JOHN W. FRANCIS, M.D.,

Late Professor of Materia Medica, Institutes of Medicine, Medical Jurisprudence, Obstetrics, and the Diseases of Women and Children in the University of the State of New-York; Member of the Medical and Chirurgical Society of London; of the Wernerian Natural History Society of Edinburgh; of the Academy of Natural Sciences of Philadelphia; of the Lyceum of Natural History of New-York; of the Historical Society of Massachusetts and of New-York; of the Literary and Philosophical Society of New-York, &c.

THE

SIXTH AMERICAN EDITION

OF

GOOD'S STUDY OF MEDICINE

IS DEDICATED,

BY HIS OBLIGED FRIEND,

A. SIDNEY DOANE.

New-York, August, 1935.

PREFACE OF THE AMERICAN EDITOR.

THE sixth American edition of the "STUDY OF MEDICINE" is reprinted from the fourth English edition, which was issued in London early in the present year: beside the ample additions of Professor Cooper, it contains between four and five hundred notes of a practical character, derived principally from the writings of American physicians.

It was with extreme diffidence, and with no little dread of appearing presumptuous, that the American Editor assumed the responsibility of adding notes to a work characterized by such profound learning and deep research: but he was encouraged by the consideration, that although the "Study of Medicine" has been used as a text-book for several years in this country, and is thought to be indispensable to every medical library, it contains but few allusions to the important results of American practice; while some forms of disease peculiar to this country, and the contributions of American physicians to physiology, pathology, therapeutics, and the materia medica, are, generally speaking, unnoticed in it.

In fulfilling his duty, the Editor has attempted to divest himself of local feelings; to consider the physicians of the United States as belonging to one family; to be just to all; and to present the results of their experience with fairness. How far he has succeeded, may be seen by referring to the notes marked with the letter D., for which he alone is accountable. The desire, however, of printing the new edition in such a form as to place it within the reach of every one, and the constant inquiries for the book, which, to speak technically, has been out of print for many months, obliged the publishers to limit the Editor both as to space and time. This fact will account for the brevity with which many important topics have been treated, and also for some omissions.

To those of his professional brethren who have so kindly tendered the results of their experience, the Editor returns his warmest acknowledg-

ments and thanks ; and to no one are these due more than to a personal friend of Doctor Good, Professor J. W. Francis, of New-York, not only for many practical remarks of great importance, but also for the use of his extensive library of rare books, and for a free access to his valuable cabinet of anatomical preparations, which, in many cases, has afforded the Editor an opportunity of verifying the statements of the text.

Prefixed to the "Study of Medicine," the reader will find a new "History of Medicine," by the learned and eloquent Bostock ; it forms a happy introduction to the main work, and its perusal will richly reward the careful reader.

HISTORY OF M E D I C I N E,

FROM ITS ORIGIN TO THE COMMENCEMENT OF THE NINETEENTH CENTURY.

By J. BOSTOCK, M.D. F.R.S.

CHAPTER I.

Introduction—Division of the History of Medicine into three great Chronological Periods—History of Medicine previously to its Introduction into Greece—Origin of Medicine—State of Medicine among the Egyptians—Among the Assyrians—Among the Jews—Introduction of Medicine into Greece—Chiron—Æsculapius—Machaon—Podalirius—The Asclepiadæ—Records in the Temples of Æsculapius—Ancient Inscriptions—Pythagoras—Democritus—Heraclitus—Acron—Herodicus—Gymnastic Medicine.

ALTHOUGH the primary object of this treatise is to present a view of the history and progress of practical medicine, yet it will be impossible to avoid entering occasionally into the consideration of the various theories and speculations which have so generally prevailed in the science. Medical theory and practice have been so intimately blended together, that it would be useless to attempt to separate them. The terms which are employed in works of the most practical nature are, for the most part, derived from the theory which was current at the time of their publication; and even the narrative of facts, and the direct details of experience, are, with a few exceptions, deeply tinged with the prevailing doctrines of the day, or with the individual speculations of the writer. Those who are versed in medical science, and who are acquainted with the relation which it bears to the other physical sciences, with the mode in which it is acquired, and the nature of the evidence on which it rests, will easily perceive that, in this department, it is peculiarly difficult to separate facts from hypothesis. It may, however, be asserted, that until this be accomplished, medicine can never be placed upon the basis of induction, and that this alone can give it that stability which may entitle it to be regarded as a correct science. In its present condition, it will be impossible to do more than to approximate to so desirable a state; but it will be a special object of attention in the following pages to endeavour to point out the limits between practice and theory, between facts and the opinions that have been deduced from them.

When we take an extended view of the progress of medicine, tracing it from its scanty sources, in the most remote periods of society, and observe its course, as gradually augmented by the stores of Grecian and Roman learning, obscured by the darkness of the middle ages, and again bursting forth in the copious and almost overwhelming streams of modern literature, we are naturally led to separate the narrative into three divisions, corresponding to the three great chronological periods. The first of these will comprehend the history of practical medicine, from the earliest records which we possess to the decline of Roman literature; the second will contain an account of the state of the science through what are termed the dark ages until the revival of letters; the third will commence with the establishment of the inductive philosophy, and be continued to the commencement of the nineteenth century.

In tracing the history of this science from its earliest records, it will not be necessary to devote much time to a subject which was formerly discussed with great learning and acuteness, viz. the origin of medicine. It may be sufficient to remark, that in proportion to the progress of civilization or refinement, attempts would be made to remove or alleviate the diseases, and to repair the injuries to which the body is constantly incident. Subject as it is at all times to the influence of various noxious agents, and to a consequent derangement of its functions, to painful affections of various kinds, and to the loss or depravation of its powers or actions, we must conceive that mankind would be anxious to remove or relieve these evils. The means that would be employed must have been, in the first instance, extremely imperfect, and frequently ill-directed. They may have been suggested by the effects of certain kinds of food, or by the operation of certain external agents on the body: some analogies may have been derived from the spontaneous actions of the system, by observing the natural efforts of the constitution to remove certain causes of disease, or to relieve the patient when suffering from their effects. Thus, in the earliest periods of society, mankind must have been aware of the relief which was obtained in the derangements of the alimentary canal by an evacuation of its contents, and would probably have discovered, incidentally, that certain vegetable substances promoted this operation. In the external injuries to which the body is subject, more especially in a rude state of society, means would early be had recourse to for procuring present ease from pain, or for removing the obvious danger to life which would so frequently follow from various causes. It would soon be found that the pain was diminished by excluding the wounded part from the air, or from other extraneous substances; that by certain modes of pressure, the flow of blood might be restricted; and that in some cases an increased and in others a diminished temperature gave immediate ease to the patient, and tended to promote the ultimate cure. A rude species of medical and surgical practice of this description has been in all cases found to exist in newly-discovered countries, even when in the most barbarous state; while it has been observed, generally, that the improvement in the healing art has been nearly in proportion to the advancement of the other arts of life, and to the gradual progress of knowledge on all subjects intimately connected with our existence or welfare.

The historical records which we possess respecting the progress of practical medicine are scanty and uncertain; but so far as they extend, they coincide with the view of the subject taken above. The writers who have investigated this point with the greatest learning and assiduity, inform us that Egypt was the country in which the art of medicine, as well as the other arts of civilized life, was first cultivated with any degree of success, and that it had advanced so far as to have become a distinct profession. We are not, however, informed in what degree or to what extent that distinct appropriation was carried; whether medicine was made the exclusive business of certain individuals, who were regularly instructed for that purpose; whether it was attached to certain public functionaries, especially to the priests; or whether persons in different situations applied themselves to the practice of medicine from a real or supposed superiority in their skill and in their knowledge of the treatment of diseases. The probability, however, is, that the priests of the Egyptians were at the same time their physicians. This appears to have been the case among the Jews and the Greeks, who are supposed to have borrowed from the Egyptians many of their institutions; and indeed it seems to be the natural progress of society in its earlier periods, when the priests were generally the depositaries of knowledge of all kinds, and when they confined it as much as possible to their own use, for the purpose of maintaining their influence over the rest of the community.

From some remarks which are made incidentally in the writings of the ancients, respecting the medicine of the Egyptian priests, it would appear that it consisted in a great measure of the employment of magical incantations, and, so far therefore as it effected the cure of disease, must have operated through the medium of the imagination. This has been in all cases the first step in the art of medicine, if it may be so called, and its efficacy must have been in exact proportion to the ignorance and superstition of the people on whom it was exercised.*

A circumstance respecting the practice of medicine in Egypt is mentioned by

* *Le Clerc, Hist. de la Médecine, par. i. liv. i. chap. 12.*

Herodotus as existing when he visited that country, and which it may be presumed was transmitted from a much earlier period, that certain individuals treated certain diseases only.* This division into separate branches might, at first view, seem to indicate a degree of manual dexterity and of minute observation in certain departments. But, independent of any other consideration, we may rest assured that the science must have remained in a state of complete degradation, when we bear in mind that it was the custom in Egypt, as it is in the present day among many of the nations of the East, to transmit the same occupations from father to son, through a number of successive generations. This practice, although it may be favourable to the perfection of an art, or even of a science, in some of its minute details, must furnish an almost insurmountable obstacle to its general improvement, or to the development of the powers and faculties of the human mind.

Although we are in the habit of considering Egypt as the parent of the arts and sciences, the empire of Assyria has been supposed, by many learned men, to possess a greater claim to this distinction. Perhaps the priority of invention may be justly awarded to the Assyrians, but the memorials which they have left behind them are so scanty, that the degree of excellence to which they arrived is almost entirely conjectural. The priests of this nation, as in all other cases, appear to have been the depositaries of all the learning of the times, and of that of medicine among the rest. We have reason to suppose that their practice consisted of little more than the dexterous application of magical arts, and such other means as tended to impress the minds of the people with a sense of their power over the operations of nature, while any actual information which they possessed was carefully concealed under the guise of mystery and superstition.†

In the writings of Moses there are various allusions to the practice of medicine among the Jews, and more especially with regard to the treatment of leprosy. The priests appear in this, as in other cases, to have been the practitioners; the treatment consisted principally in certain regulations for the purpose of promoting cleanliness and preventing contagion, together with various ceremonies, which, so far as they could affect the patient, must have acted entirely on the imagination.‡ So little is known respecting the state of the arts and sciences in the other countries of the East, at these remote periods, that it is scarcely necessary to allude to them in this place. We shall only remark, that the imperfect and scanty notices which we possess on this subject would lead us to conclude, that the practice of medicine was even in a less advanced state than among the Egyptians, its progress being regulated by the greater or less degree of refinement or civilization of the respective countries, but in no case having advanced beyond the state of implicit credulity and gross superstition.§

After having given an account of the state of medicine among the ancient Egyptians and other contemporary nations, as far as can be gleaned from the scanty records that remain on this subject, we must follow it into Greece, and trace its progress from the period of its first introduction in the remote and semi-fabulous ages of their *demigods* and *heroes*, until it acquired the rank of a science under the genius of Hippocrates. It is generally admitted, that although Greece cultivated the arts and sciences with so much success, yet, in the first instance, she borrowed them from the neighbouring nations; principally, as it would appear, from Egypt, and in some cases from Phœnicia.|| To certain individuals who migrated from these countries, the Greeks themselves were in the habit of referring the introduction of many of the most useful inventions; and during a considerable space of time all those who were desirous of acquiring a larger share of knowledge, either

|| Vide *Bryant*, ubi supra, et v. ii. p. 426 et seq. et alibi.

theoretical or practical, than was possessed by their countrymen, visited Egypt, as the great storehouse of science and learning. It is from this cause that we find so much analogy between the divinities that were worshipped in the two countries, as inventors or patrons of the various arts and sciences. For although they acquired new names on their being transferred into Europe, yet their attributes, and even their forms, clearly demonstrate their origin. This is particularly the case with respect to medicine, so that in the Orus and Thouth of the Egyptians we may recognise the prototypes of the Apollo and Hermes of the Greeks.*

It is not until comparatively at a late period, approaching to that of the Trojan war, that we find the names of actual personages who practised medicine in Greece: and of these, it is probable that some were natives of either Africa or Asia, who brought with them the information which they had acquired in their respective countries. Of those whose history is better known, and who were acknowledged to be of Grecian origin, it was the general custom to travel into Egypt for the purpose of obtaining a knowledge of their art, and with this view they submitted to a system of rigid discipline, and to a variety of irksome and burdensome ceremonies; and after all this laborious process, so far as the science of medicine is concerned, the result seems to have been little more than the knowledge of magic and incantations, with some rude notions respecting the application of external remedies for the cure of wounds and of cutaneous diseases, with a very imperfect idea of the anatomy of the human body, and a very inadequate conception of its functions.†

The first native of Greece who is more particularly singled out, as having introduced the art of medicine to his countrymen, is the centaur Chiron. There is much mystery attached to his character and to every thing connected with him, but what we may consider as the most probable conclusion is, that he was a prince of Thessaly, who lived about the thirteenth century before the Christian era; that he was distinguished above his contemporaries for his knowledge of the arts of life; and that, after the manner of his countrymen, he was frequently seen on horseback, so as to give rise to the fabulous account of his compound form. He is particularly celebrated for his skill in medicine and in music; a combination, it may be remarked, that was said to have existed in many other individuals. We are not informed by what means he obtained his superior knowledge in medicine; but there are various circumstances which lead us to conclude that it was at that time regarded rather as a part of the education of all men of rank, than as attached to a particular profession. We accordingly find that he instructed the Argonauts in medicine, and the heroes who were engaged in the siege of Troy; and that all the kings and warriors of that period were more or less acquainted with the treatment of wounds, and even with the practices which were adopted for the cure of internal diseases.‡

But although Chiron has the reputation of having introduced the art of medicine into Greece, it is to his pupil Æsculapius that, by the common consent of antiquity, is ascribed the merit of having first devoted himself to the cultivation of medicine as a science, and of having made it a distinct object of pursuit. The improvements which he made in the art were so considerable as to have induced his countrymen after his death to pay him divine honours, to designate him as the god of physic, to erect temples to him in various parts of Greece,§ and to derive his origin from Apollo himself. His history, when divested of all the fabulous appendages that were attached to it by his contemporaries, appears to be, that he was a native of Epidaurus, that he was exposed in his infancy, probably in consequence of his illegitimate birth, that he was accidentally discovered by a shepherd, and placed under the care of Chiron. His death was said to have been caused by the jealousy of Pluto, in consequence of the number of individuals whom he rescued from the grave; from which tale we may at least conclude that his reputation, as a successful practitioner, must have been much higher than that of any of his contemporaries.||

|| Diodorus Siculus, lib. iv. §. 71. Hyginus, fab. 49 et alibi. Le Clerc, par. i. liv. i. ch. 11-16.

According to the custom of that age, he transmitted his profession to his sons Machaon and Podalirius, who accompanied the Greeks in the Trojan expedition, and are celebrated in various passages of the Iliad for their medical skill.* From the incidental mention that is made by Homer and the early Greek writers of the nature of the remedies that were employed by these individuals or their contemporaries, it will appear that their practice was principally surgical, and nearly confined to the treatment of wounds, and that, with respect to internal diseases, these were for the most part conceived to be the immediate infliction of the Deity, and were therefore abandoned as incurable, or at least were to be obviated only by charms and incantations, and that the arts of magic formed no inconsiderable part even of their surgical practice.†

The practice of medicine remained for a considerable time hereditary in the family of Æsculapius, and in a great measure confined to it. His descendants obtained the name of Asclepiadæ; they were the priests of his temples, and presided over and directed the rites and ceremonies.‡ These temples, indeed, became a species of hospitals, to which patients resorted from all quarters for the relief of the diseases with which they were affected. Under the direction of the priests of these temples they underwent a variety of ceremonies, the immediate effect of which must have been principally upon the imagination. Some, however, of the practices which were enjoined were of a dietetic nature, and were directly conducive to temperance and cleanliness; such as frequent ablution, and the abstaining from certain kinds of food. To these, if we add that the temples were generally erected in healthy situations, that the patients enjoyed rest and leisure, and that the mind was interested by a succession of new and pleasing impressions, we may suppose that they would be placed under circumstances not a little resembling those which are found so conducive to health by the invalids who frequent the medicinal springs and other analogous establishments of modern times.§

Although the accounts that have been transmitted to us respecting Æsculapius would lead us to conclude that he was a real personage, who actually possessed a greater degree of medical skill than any of his contemporaries, yet his whole history is so involved in fable and mystery, that it is impossible to obtain any correct idea of the details of his practice. It has been observed above that it was probably, in a great measure, surgical, and even confined almost exclusively to the cure of wounds or recent injuries. The treatment of these may be considered so far judicious as it was simple; it consisted in removing all extraneous bodies, in placing the parts as much as possible in their natural position, in fomentations and ablutions, and in the application of certain vegetables, which were supposed to be possessed of balsamic or styptic properties. Wine and other articles of a more stimulating nature were also used, while oleaginous substances were employed nearly with the same intention as in modern times, to defend the part from the air or other external agents, together with bandages and other means of mechanical support. We have no distinct evidence how far internal remedies were administered; for the most part they relied on magical arts and incantations, and although we have reason to believe that certain vegetable products were occasionally employed as internal remedies, we are scarcely able to discover what was the object of the practitioner, and we are frequently unable to ascertain what were the plants that were employed.||

But scanty and imperfect as is our knowledge of the state of medicine in the age of Æsculapius, after his death and that of his sons Machaon and Podalirius we have a long period, extending even to several centuries, during which we have still less information respecting the history and progress of the science. We have

not a single improvement of any importance recorded as having taken place during this long interval, nor have we the names of any individuals transmitted to us who were of sufficient eminence to be distinguished above their contemporaries. We learn that the practice of medicine was entirely confined to the Asclepiadæ, who were the guardians or superintendents of the temples that were erected in honour of Æsculapius. It may be inferred from the very scanty materials which we possess on the subject, consisting entirely of allusions or indirect accounts, scattered through the works of the older poets and historians, that they sedulously kept up the system of rites and ceremonies, which had been handed down to them from still more ancient practitioners, that they carefully preserved to themselves the sole management of the art over which they presided, and we cannot doubt made use of the influence which they acquired over the minds of their contemporaries for the purposes both of gain and of ambition.* But although we regard the general system of the priests of Æsculapius to be nothing more than a tissue of mystery and delusion, it is very probable that the ample opportunities which they possessed of witnessing the phenomena of disease in all its forms, might enable them to obtain much valuable information respecting the nature and tendency of the morbid actions of the body, and of the effects of certain agents upon them. Men possessed of superior talents and sagacity would naturally profit by these advantages, and we accordingly find that some of these temples acquired a high degree of celebrity, in consequence of the supposed skill of the priests that were attached to them. These opportunities of acquiring experience were much facilitated by a practice which generally prevailed among the patients, whenever they were cured of their diseases, of depositing in the temple a votive tablet, on which was inscribed a narrative of the case, including a statement of the symptoms of the disease, and the means adopted for its removal. The temples were thus converted, to a certain extent, into schools of medicine, and as these records were religiously preserved, they became the repositories of much important information, which must have gradually led to an improvement in the art. Of the numerous temples that were dedicated to Æsculapius, there were three which acquired peculiar celebrity, those of Cos, of Gnidos, and of Rhodes; we are informed that Hippocrates made great use of these records, and it has even been supposed that one of the treatises which is generally ascribed to him, "*Coacæ Pranotiones*," was composed from the records which he procured from the temple of Cos.

Some ancient inscriptions have been discovered by the researches of the learned antiquaries of the last century, which would appear to consist of memorials of this kind; and from these specimens we may form some idea of the nature of the information that would be conveyed by them. For the most part they state little more than the name of the disease, together with a very brief account of the means adopted for its relief, which in many cases depended entirely upon certain ceremonies, and in others upon the application of remedies, which, we may venture to assert, could have no physical operation.† Still, however, some experience of the nature and treatment of disease might have been conveyed by their means, and of this we may presume that an individual of a sagacious mind would have availed himself for the improvement of his art.

Among the few circumstances that are transmitted to us respecting the principles and practice of the Asclepiadæ, we are informed that the priests connected with the two rival establishments of Cos and Gnidos devoted their attention, in some measure, to different objects; those of the former assumed more of a philosophical cast, attempting to unite reasoning with experience, while the latter attached themselves solely to the observation and collection of mere matters of fact. Hence it would appear that a foundation was thus early laid for the two great sects of the Dogmatists and the Empirics, which long divided the medical world, and the influence of which is, even at this day, not altogether destroyed. I may remark, however, that the philosophy of the school of Cos, if it may be so called, was founded upon such totally incorrect principles, and upon so fallacious a basis, that little immediate benefit was derived from it, and that it was only useful so far as it might lead them to exercise their intellectual powers, and enable them to reason

* *Lucian*, in his "*Philopseudes*," gives an account of various medical superstitions which prevailed at a later period, many of which were probably transmitted from the empirics of antiquity. See *Tooke's Trans.* v. i. p. 87 et seq.

† *Gruter*, *Corp. Inscript.* a Grævio, pl. 17 et alibi. *Ackermann*, *Opuscula*, Diss. 3, §. 3, by *Hundertmark* and *Carpzov*.

more correctly on medical subjects. By the mode in which Hippocrates speaks of certain practices, such as bleeding and the administration of emetics, purgatives, and other analogous medicinal agents, we may infer that they were in common use among his contemporaries, and probably had been so for a long time before him. We may in some instances obtain a knowledge of the vegetable substances that were employed in these early ages, as well as of the individuals who introduced them into practice by the names which were afterward imposed upon them by the ancients. It must indeed be obvious that the indication derived from these names is far from being decisive, as applied to any particular case; but we derive a general inference from it as to the nature of the articles employed, while they serve to point out the persons who were supposed to have been the most eminent for their skill or their science.

Some centuries had elapsed, during which the practice of medicine continued altogether in the hands of the priesthood, and under their control had remained nearly stationary. It had been exercised, for the most part, for the purpose either of direct emolument, or for the still more selfish purpose of maintaining their influence over the minds of the people, when it began to be cultivated by a different description of persons, much more likely to produce a spirit of improvement, and from whom in reality it derived its first impulse. It was during the sixth century before the Christian era that the genuine principles of philosophy first made their appearance in Greece; and among the other topics which then became the subject of investigation, the powers and functions of the human body were examined with considerable attention. This led to an inquiry into the nature and cause of diseases, and to the means of their removal; and although a long period elapsed before much actual advance was made in the knowledge of pathology or of the practice of medicine, yet we observe the effect of a more correct mode of reasoning, and may perceive that the strongholds of mystery and superstition, although not destroyed, were at least in some degree weakened.*

The celebrated name of Pythagoras may be mentioned as the first of this class respecting whom we have any accurate information, and even his history is enveloped in much obscurity. We may, however, conclude with certainty that he devoted the greatest portion of a long life to the pursuit of natural knowledge; that he made many considerable advances in various departments of science, and among others in the knowledge of the structure and actions of the human frame. It has been supposed that he dissected the bodies of animals, and hence acquired a certain acquaintance with anatomy; and that he publicly taught what he knew on this subject to a large assembly of students, who came from all the civilized parts of Greece and Italy to Crotona, where he established his school. We are informed that, for the purpose of acquiring knowledge, he travelled into those countries which, previously to his time, were regarded as the depositories of knowledge, particularly Egypt, where he is said to have passed no less than twenty-two years, and probably also Chaldea and some parts of Eastern Asia. From what has been stated above, we may form some conception of the nature of the knowledge that he would obtain from these sources, and we may conclude that he must have been possessed of a very superior mind to have been capable of extricating himself from the trammels of superstition and bigotry, in which every thing connected with those countries was involved.†

We are scarcely able to determine in what degree he directly improved the practice of medicine; it is probable, however, that as he did not make it his profession, but studied it only in connection with the other branches of natural philosophy, the actual additions which he made to it were not considerable.‡ This we may also conclude to have been the case with many of his pupils, who were among the most justly celebrated philosophers of that and the succeeding age. They may all of them be regarded as belonging to the school of Pythagoras, inasmuch as they cultivated natural knowledge by means of observation, and even occasionally of a rude kind of experiment; and although none of them were exclusively devoted to the study of medicine, yet they gradually and indirectly contributed to its advancement, so as to prepare the way for one of those great and commanding

geniuses who occasionally make their appearance, and by their intellectual ascendancy produce such important revolutions in the world of science: it is unnecessary to state that I here allude to Hippocrates.

During the interval from Pythagoras to Hippocrates there are few names that require any particular notice as improvers of medicine. Democritus* and Heraclitus† were among the most illustrious followers of Pythagoras, but they became famous rather from the ingenuity with which they supported their peculiar hypotheses than from the additions which they made to actual knowledge. They applied respectively their favourite doctrines of atoms and elements to explain the phenomena of disease, and even the operation of remedies; but, it is unnecessary to say, with little real advantage. The former of these philosophers, however, deserves honourable mention from the attention which he paid to the study of comparative anatomy; and it has been conjectured that he so far rose superior to the prejudices of his age as to venture upon the dissection of the human subject.

The name of Acron is mentioned by Pliny‡ as among the first who attempted, upon any general principles, to apply philosophical reasoning to the science of medicine; but we have scarcely any knowledge of his history or character, nor have we any memorials left of the principles which he adopted.§ We may also select the name of Herodicus as having been considered the inventor of what was styled gymnastic medicine,|| which was regarded by the Greeks as a very important branch of the art. Schools for the practice of the gymnastic exercises were established in various parts of Greece, and were placed under the direction and superintendence of persons especially trained for the purpose, who took charge of the health of their pupils, and who appear to have undertaken the treatment both of the accidents which occasionally occurred in their establishments, and also, when necessary, of internal diseases. These gymnasiarchs, as they were styled, must in this way have acquired a certain degree of information respecting the nature of disease, and seem to have been considered as among the most skilful practitioners of the age in which they lived.¶

CHAPTER II.

An Account of the Opinions and Practice of Hippocrates and his Contemporaries—Remarks on the History and Education of Hippocrates—High Estimation in which he was held—Remarks on his Character and Acquirements—On his Works—Account of his Principles and Doctrines, his Physiology, Pathology, Anatomy, and Practice.

WE now enter upon the history of an individual of very distinguished character and acquirements, who was destined to effect a complete revolution in his profession, and to introduce a system which may be considered as having laid a foundation for all its future improvements. The contemporaries and immediate successors of Hippocrates were so sensible of his merit, that he acquired from them the title, which he has since retained, of Father of Medicine; and it may be confidently affirmed that the science is more indebted to his genius and ability than to that of any single individual. It is a little remarkable that, notwithstanding the great celebrity which he attained, we have no very correct knowledge of his history, of the mode of his education, or of the means by which he acquired his wonderful pre-eminence. All that we are able to learn on these points with any degree of

§ *Le Clerc*, par. i. liv. ii. ch. 7.

|| *Le Clerc*, par. i. liv. ii. ch. 8. *Mercurialis*, *De Arte Gymnastica*. *Schulz*, p. 192 et seq. *Barbier*, *Dict. Scien. Méd. art. "Gymnastique."* *Ackermann*, par. 2, cap. 6.

¶ *Plato*, *De Repub. passim*, et *De Leg. lib. vii.* *Schulz* has judiciously summed up, in a series of general propositions, the history and progress of medicine up to the period at which we are now arrived, p. 201, 2.

certainly is, that he was brought up among the Asclepiadæ, who were attached to the temple of Cos; that he studied medicine under Herodicus, and that he embraced the philosophical hypothesis of Heraclitus: he is also reputed to have been a lineal descendant, in the eighteenth degree, from Æsculapius, and may therefore be supposed to have been devoted to the profession from an early period of life, and must have had access to all the records which were accumulated in the establishment to which he belonged. These circumstances may have had the effect of originally directing his mind to the pursuits in which he afterward became so eminent; but we must suppose that he possessed from nature a genius singularly adapted to the advancement of medical science, by which he was enabled so far to surpass all those who were placed in situations equally advantageous. We are informed that he spent a considerable portion of his life in travelling through foreign countries, partly for the purpose of obtaining information, and partly from the circumstance of his assistance being required to undertake the cure of persons of rank, to arrest the progress of epidemics, or to check the ravages of endemic diseases. The works that he left behind him are very numerous, and, considering their antiquity, they may be regarded as in a tolerably perfect state.

Unfortunately, however, to those which appear to have a just claim to be considered as his genuine productions there are appended a number of others, which it may be concluded are spurious, either written by his pupils or successors, or fraudulently attached to his name in consequence of his great celebrity. Many eminent critics have exercised their ingenuity in endeavouring to separate the genuine from the spurious writings of Hippocrates; and in such estimation was he held, that for many ages a main object with all writers on medical topics was to comment on the works of Hippocrates, to elucidate his principles by subsequent observation, or to support their respective doctrines by his authority. He is mentioned with great respect by Plato, Celsus, and Pliny, and by others among the ancients: Galen speaks of him with a degree of almost enthusiastic admiration; and at the revival of letters the most learned men of the times devoted themselves to the elucidation of his works by glossaries, commentaries, and criticisms of all descriptions. In Italy, Germany, and France, where learning first began to revive, and where the earliest universities were established, we have, among other illustrious names, those of Alpinus, Cornarius, Hollerius, Ballonius, Mercurialis, Fernel, Heurnius, Sennert, Fœsius, Riolan, and Duret,* who, however they might differ in their opinions and practice, all coincided in regarding Hippocrates with equal respect, and considered him as having first placed the study of medicine on its correct basis.†

We are hence naturally led to inquire what were the circumstances, in the intellectual or literary character of Hippocrates, which produced this powerful impression, and perhaps we may assign the following as among the most influential. He appears to have had the sagacity to discover the great and fundamental truth, that in medicine, probably even more than in any other science, the basis of all our knowledge is the accurate observation of actual phenomena, and that the correct generalization of these phenomena should be the sole foundation of all our reasoning. Every page of Hippocrates proves that he was not without his speculations and hypotheses, but at the same time we perceive that, for the most part, they were kept in subjection to the result of observation, and that, when they appeared to be in opposition to each other, he had the wisdom to prefer the latter. Hence his descriptions of particular diseases, after all the revolutions of customs and habits, both moral and physical, are still found to be correct representations of nature, while his indications of cure, and the treatment derived from them, are generally rational and practicable. When we reflect that at this period anatomy was scarcely practised,‡ that physiology was almost unknown, that the *materia medica* was nearly confined to vegetable substances, and of these to such as were indigenous to Greece and the neighbouring countries, our admiration of the skill and talents of Hippocrates will be still further increased, and we are induced to regard him as

* In designating the names of authors who flourished after the revival of letters, it is somewhat difficult to determine whether we ought to employ their actual or their latinized names: I have adopted the former where it could be done without ambiguity or the appearance of affectation.

† *Conring*, Intr. cap. 3. §. 8. et alibi. *Haller*, Bibl. Med. Prac. lib. vi.; it is entitled "*Schola Hippocratica*," and is carried down to the beginning of the seventeenth century.

‡ *Gruener*, *Analecta*, diss. 2. "Hippocrates, corpora humana insecurit necne?" He discusses the question with much learning and candour, and decides in the negative.

one of those rare geniuses, who so far outstrip their contemporaries as to form an era in the history of science.

With respect to the particular improvements which he introduced into the practice of medicine, I may remark, that one of the first importance was the narration of individual cases of disease,—a plan which may perhaps have been suggested to him by the votive tablets deposited in the temple of *Æsculapius*, but upon which he so far improved as to be entitled to the merit of an inventor. The second point on which I shall remark, was his method of endeavouring to remove particular symptoms by carefully noticing what have been termed the *juvantia* and the *ledentia*, watching the effect of his applications, and proceeding, by a cautious analogy, from individual facts to more general conclusions; and hence deducing his indications of cure from the operations of remedies, not from any preconceived or abstract principles, which were generally either fallacious or inapplicable. Hence his practice may be characterized as consisting in what has been termed a rational empiricism, where we first ascertain the fact, and afterward reason upon its consequences.

In speaking of the writings of Hippocrates, it may be proper to remark, that the most complete edition of them, in all respects, is that of Fesius, in which every circumstance is attended to that can illustrate them or render them more easily intelligible. He has given a list of all the commentaries and criticisms that had been written upon them, which, at the time of his publication, in the year 1595, would of themselves have formed an extensive library. It appears from this list that no less than one hundred and thirty-seven authors had published on the subject of the aphorisms alone. It was remarked above that many of the writings which are commonly ascribed to Hippocrates, or at least are published in the collection of his works, are supposed not to have been his genuine productions; and hence it has been an object of interest with many eminent critics to distinguish the one from the other. It will not be necessary for me to enter into these discussions in this place; I shall only remark, that the number of treatises which are admitted to be certainly genuine is very small, compared to the whole number popularly ascribed to him. Of those which are printed in the ordinary editions of his works, which amount to more than sixty, *Mercurialis*, *Haller*, *Gruner*, and other critics, conceive that there are a few only which were actually written by Hippocrates, and *Aekermann* has even reduced the number of the genuine works to ten.*

In ascertaining what were the real opinions and practices of Hippocrates, besides the difficulty of discriminating the genuine from the spurious productions, we have a further difficulty arising from the peculiarity of his style. This is admitted to be brief and abrupt, and to be full of ideas, compared with the number of words employed to convey them; so that it appeared somewhat obscure even to his contemporaries and immediate successors. *Erotianus*, who lived in the first century of the Christian era, thought it necessary to write a glossary for the express purpose of elucidating his phraseology; and the immense number of commentaries which have appeared, and which continued to be published until the commencement of the eighteenth century, must be regarded, not only as a tribute to his extraordinary merit, but, in some measure, as an indirect censure of his style. But after making all due allowance for these peculiarities, after rejecting all the doubtful works and obscure passages, and resting more upon the general scope and tendency of the treatises than on particular words and phrases, we have sufficient evidence left us of the nature of his principles, both as regards theory and practice. Although it is principally in the latter capacity that we are now to regard Hippocrates, yet it will be proper to make a few remarks upon his acquirements in the analogous departments of science.

With respect to his philosophical tenets, it appears that the father of medicine must be classed generally among the Pythagoreans, and in the particular sect or school of *Heraclitus*. The leading doctrine of this philosopher was, that fire is the prime origin of all matter, and that by the collision and peculiar combination of its particles, which are in perpetual motion, the four elements are produced.† From

† *Enfield*, b. 2, c. 14, v. 1, p. 436 et seq.

this doctrine Hippocrates derived his leading principles of pathology; it lies at the foundation of all his medical hypotheses, and is brought forward in various parts of his works. But although, like all his contemporaries, and indeed nearly all his successors up to the present day, he assumed certain theoretical principles; yet, as we remarked above, he had the extraordinary sagacity to perceive the necessity of detaching medicine from what was then styled philosophy. He professed to examine the phenomena of disease in the first instance, to ascertain what were the natural powers and properties of the animal frame, how far these were affected by external circumstances and by morbid causes, and hence to derive his curative indications and his mode of treatment. It is in the writings of Hippocrates that we observe the first traces of what is properly styled physiology, *i. e.* an account of the functions and powers of the living body. Although some of his opinions were derived from the school of Pythagoras, and savour of its mysticism and obscurity, yet others appear to have been original, and founded upon a much more correct and philosophical view of the subject. We owe to him the invention of the hypothesis of a principle, to which he gives the appellation of nature (*φύσις*), which influences all parts of the corporeal frame, superintends and directs its motions, and which is possessed of a kind of intelligence, so as to promote all the actions which are beneficial, and repress those which have an injurious tendency. In addition to this general principle, he conceives of others of a subordinate nature, which he styles powers (*δυνάμεις*), which are more particularly concerned in the action of the various functions of the body. The body itself is supposed to consist of the four elements, combined in different proportions in different individuals, so as to produce an original difference in the constitution of the body, giving rise to the four temperaments. These influence both the intellectual and the corporeal part of our frame, and lay a foundation for disease independent of circumstances, and cause these circumstances to operate in different modes and in different degrees in different individuals.

One of the leading pathological doctrines of Hippocrates was, that the fluids are the primary seat of disease; a doctrine which, under the denomination of the Humoral Pathology, became the prevailing opinion of all sects and of all theorists, until the commencement of the eighteenth century. The combination of the four elements with the four states or qualities with which they were affected—of hot, cold, moist, and dry—gave rise to the four fluids or humours of the body—blood, phlegm, bile, and black bile,—which originally tended to produce the four temperaments, and which in their turn contributed to the excess or defect of each of the humours.

Another of the most important doctrines of Hippocrates is that of crises, or the natural tendency of diseases to a cure at certain stated periods, depending upon a natural train of actions, which, when proceeding in their due course, terminate in the removal of the morbid action. These supposed crises were, for the most part, evacuations of various kinds, especially by the bowels or the skin; and hence the regulation of these evacuations led to his most important indications, and became a main part of his practice. There is no subject on which Hippocrates showed more sagacity and accurate observation than in watching the effect of external agents upon the system,—such as temperature, the influence of the atmosphere, the effect of particular situations, of the seasons, and other analogous circumstances. In most of these cases the causes were obscure, and he frequently erred in his attempts to explain them; but his observations were correct, and contributed materially to the success of his practice.

The extent of knowledge which Hippocrates possessed on the subject of anatomy has given rise to much learned discussion. While his admirers were unwilling to admit that he was deficient in any of the departments of medical science, and attempted to prove that he had acquired a correct knowledge of the structure of the body, it has been contended, on the other hand, that on this point his information was very imperfect. This may be readily supposed to be the case from the abhorrence with which the dissection of the human subject was regarded at that period, and from the little attention which was paid even to comparative anatomy. There are likewise other considerations of an especial nature, which lead us to conclude that he had little knowledge of the internal structure of the body, or of the relation of its different parts to each other. Notwithstanding, therefore, the claim which has been set up for Hippocrates, by some of his devoted advocates, to a knowledge of the circulation of the blood, and other claims equally extravagant

and unfounded, we may conclude, with the learned and candid Le Clerc, that the knowledge which Hippocrates possessed of anatomy was little, if at all, superior to that of his contemporaries.*

After these brief observations on the theoretical doctrines of Hippocrates, and of the knowledge which he possessed in the various departments of medical science, we must conclude this chapter with a somewhat more minute account of his practice. Although he has published no regular treatise on practical medicine, nor laid down any specific rules on this subject, he has given us, in several parts of his works, a minute detail of his treatment of various diseases, so that we are enabled to ascertain, with considerable minuteness, the general principles on which he acted, as well as the mode in which he applied them. The great principle which directed all his indications was the supposed operation of "nature," to which we have referred above, in superintending and regulating all the actions of the system. The chief business of the physician is to watch these operations, to promote or suppress them according to circumstances, and perhaps, in some rare cases, to attempt to counteract them. The tendency of this mode of practice would be to produce extreme caution, or rather inertness, on the part of the practitioner, and we accordingly find that Hippocrates seldom attempted to cut short any morbid action, or to remove it by any decisive or vigorous treatment. Considering the state of knowledge on all subjects when he lived, it must be admitted that this plan of proceeding was much more salutary than the opposite extreme, and that it had likewise the good effect of enabling the practitioner to make himself better acquainted with the phenomena of disease, and, by observing the unaided efforts of nature, to form his indications with more correctness, and to determine to what object he ought more particularly to direct his attention. It has been remarked, that a man who is possessed of an acute and penetrating genius, however strongly he may be attached to a favourite hypothesis, contrives to adapt it to the information which he acquires; and this was in some measure the case with Hippocrates. For, notwithstanding the grand principle of the all-sufficient and unerring superintendence of nature, we have another general principle brought into view, which appears altogether of an opposite tendency, viz. that a disease is to be cured by inducing a contrary state of the system, or a contrary action in the morbid part. Thus, repletion is to be relieved by evacuation, and the effect of excessive evacuation to be removed by inducing repletion; the excess or defect of any of the humours or qualities is to be relieved by the employment of such means as may augment or diminish the contrary humour or quality. Perhaps it may be said that, in these cases, the practitioner is in fact only anticipating the operation of nature, or producing that change which would naturally ensue, were there not some unusual counteracting cause which prevented or repressed it. But it is of comparatively little consequence in what way he reconciled this apparent discordance; we have every reason to feel assured that this mode of treatment is frequently correct, and Hippocrates evinces the superiority of his genius by not suffering his judgment to be warped, even by the influence of a favourite hypothesis.

A third principle which very materially affected the practice of Hippocrates was the doctrine of critical evacuations, to which we have alluded above. As diseases were supposed to originate in the prevalence of some morbid humour, so when they are suffered to run their course without interruption, they are relieved by the discharge of the humour, and consequently the promotion of this discharge becomes an important indication, which it is often easy to accomplish, and which proves very effectual. Hence an important part of his practice consisted in the employment of evacuations of various kinds, and especially of purgatives, of which he used a great variety, and administered them with great freedom. This, indeed, was the only part of his practice which can be considered as decidedly active, but even here we do not perceive that he transgressed the limits of prudence, while in the selection of the remedy and its adaptation to each particular case, he manifested considerable judgment and sagacity. With the same intention he prescribed diuretics and sudorifics: he drew blood both by the lancet and the scarificator; he applied the cupping-glasses; he administered injections and inserted issues. He made very frequent use of external applications, such as ointments, plasters,

* *Le Clerc*, par. 1, liv. iii. ch. 3. *Schulz*, per 1, sec. 3, cap. 2, §. 1-8. *Sprengel*, t. i. p. 302 et seq. *Græner*, *Analecta*, No. 2. *Lauth*, liv. iii. passim.

liniments, &c., and was familiarly acquainted with the effects of external temperature. His *materia medica* was tolerably copious, and embraced many articles which still retain their place in our pharmacopœias. They were almost exclusively of vegetable origin, for the preparations which depend on chymical processes, such as metallic salts and oxides, the strong acids, with the spirituous compounds, were then totally unknown.

One important part of medical practice to which Hippocrates paid particular attention was the regulation of the diet; in this he displayed much sagacity and discernment, as well as on all points connected with the management of his patients, with regard both to the cure and prevention of disease. He appears to have been the first who noticed what has been called the epidemic constitution of the seasons, that inexplicable condition of the atmosphere, or of those influences to which the body is exposed, which appears to render it more or less obnoxious to certain morbid causes, and even to generate these causes at certain periods, without our being able to refer their production to any more general principle.

The tendency of the practice of Hippocrates to allow the operations of the system to pursue their course without interruption, united with his natural sagacity, enabled him to acquire great skill in prognostics, so that there are no parts of his writings which exhibit more decisive marks of a superior understanding than those in which he treats on this topic. Upon a review of the character and writings of this celebrated individual, we conceive that we are warranted in the conclusion, that while there are few persons of any age or nation who attained to greater distinction among their contemporaries, or whose memory has been more cherished by posterity, there was perhaps no one whose fame was more merited or established upon a firmer foundation.*

CHAPTER III.

History of Medicine from the Time of Hippocrates until its Introduction into Rome—Establishment of the Dogmatic Sect—Plato—Aristotle—School of Alexandria—Erasistratus—Herophilus—Division of Medicine into different Departments—Into the Dogmatic and Empiric Sects—Their General Principles.

We have not much to add respecting the state of medicine during the period which immediately succeeded to the death of Hippocrates. The advance which he made in the science, and the improvement which he introduced into the practice, were so considerable, that no one appeared for some centuries who was able to proceed, at least in any considerable degree, beyond the point of perfection to which it had been brought by the great father of medicine. In conformity with the custom of the times, Hippocrates transmitted his profession to his sons Thesalus and Draco, and we are informed that it continued to descend in the direct hereditary line for several successive generations. Polybus, his son-in-law, is singled out as having fully maintained the credit of his illustrious relative; and it is even said that many of the writings usually ascribed to Hippocrates are in reality the production of Polybus.†

The only other names which we meet with in the annals of medicine among the Asclepiadæ, that are in any considerable degree distinguished, are Dicoles of Carystus and Praxagoras of Cos. The former of these obtained a high reputation for his learning and practical skill: he appears to have adopted for the most part the opinions and practice of Hippocrates.‡ Of the latter, although he is enumerated among the successful improvers of the art, we have only very imperfect and unsatisfactory accounts. We are indeed informed that he paid great attention to

* *Le Clerc*, par. i. liv. iii. *Conring*, cap. 2, §. 11, et alibi. *Schulz*, per. 1, §. 3, cap. 1-4. *Douglas*, *Bibliogr. Anat.* p. 1, et seq. *Barchusen*, diss. No. 12. *Haller*, *Bib. anatomy, that he particularly noticed the state of the pulse, and derived many of his indications from this source; but we have little except the general fact of the estimation in which his name was held by his contemporaries, which can enable us to form an estimate of his merit.* The name of Chrysippus may be noticed in this place as one who appears to have been a kind of irregular practitioner, as we should style him, who did not belong to the family of the Asclepiadæ, and was principally remarkable for the innovations which he introduced into practice.† But, like too many of those whose fame is principally founded on the novelty of their opinions, we do not find much to commend in them. We are told that he did not allow, in any case, of bleeding, and that he discountenanced the employment of all active purgatives; and, in short, that he rejected many of the most powerful and effective agents in the treatment of disease.‡

Draco and Thessalus, in conjunction with their relative Polybus, are generally regarded as the founders of what has been considered as the first medical sect or school which was established upon rational principles. It obtained the name of the Hippocratean, or more generally the Dogmatic school or sect, because it professed to set out with certain theoretical principles which were derived from the generalization of facts and observations, and to make these principles the basis of practice.

Although we can have no hesitation in pronouncing this to be the correct and legitimate method of pursuing the study of medicine, yet it must be acknowledged at the same time that it is a method which, if not carefully watched and strictly guarded by prudence and sagacity, is exposed to the greatest danger of being corrupted by ignorance and presumption. Hence we may easily conceive that it would be liable to fall into the grossest errors, and to lie open to the most serious imputations, and that a fair plea would always be found for exclaiming against the introduction of what is termed theory into the practice of medicine. This abuse of the principles of the Dogmatists gave rise to the rival sect of the Empirics, who, perceiving the false reasoning of the former, and the injudicious practice consequent upon it, professed to be guided altogether by experience, and to discard all theory. For many centuries, these two sects divided the medical world; and even at this day, after all the revolutions of opinion and the improvements of science, we may observe very distinct traces of their influence. It was not, however, until a considerably later period that the Empirics formed themselves into a distinct sect, and became the declared opposers of the Dogmatists.§

Besides the individuals who belonged to the family of the Asclepiadæ, and who made medicine their particular profession or pursuit, most of the philosophers of Greece bestowed a certain degree of attention upon this science; for it appears that among the ancients a knowledge of medicine was regarded as one of the branches of philosophy which was included in a course of general education. The only two, however, of the Grecian philosophers whom it will be necessary to mention on the present occasion are Plato and Aristotle, who, although they did not compose any treatises on medicine, strictly so called, make frequent allusions to it in various parts of their writings. The former of these authors, in his dialogue styled *Timæus* and in his treatise *De Republica*, has entered into various physiological discussions respecting the functions of the body, and the supposed effect of their derangement in producing the morbid conditions of the system, and has offered various incidental observations on the practice of his contemporaries. But it does not appear that either the theory or the practice of medicine received any improvement from this philosopher. He made little or no addition to the actual stock of our knowledge in any branch of natural science, while his peculiar genius rather led him to the formation of hypotheses and speculations derived from fanciful analogies, tinged with that air of mystery which pervades most of his writings.||

Both the original turn of mind and the pursuits of Aristotle were much better adapted to improve the science of medicine than those of Plato: he made very

* *Le Clerc*, par. i. liv. iv. ch. 6. *Schulz*, p. ii. cap. 1, §. 23-8. *Sprengel*, t. i. p. 372-4.

† Pliny remarks of him, "Horum (referring to previous physicians) placita Chrysippus ingenti gravitate mutavit." *Nat. Hist. lib. xxix. cap. 1.*

‡ *Le Clerc*, par. ii. liv. i. ch. 1. *Schulz*, p. i. §. 3, ch. 5, 6. *Sprengel*, t. i. p. 365.

§ *Sprengel*, §. 4, ch. 1.

|| *Le Clerc*, par. i. liv. iv. ch. 3. *Stanley's Hist. of Phil. part v. ch. 22, p. 79 et alibi.* *Sprengel*, t. i. p. 337 et seq.

great advances in the knowledge of nature; he was peculiarly well situated for the acquisition of new information on all subjects connected with natural history, and he diligently availed himself of his advantages. He was the first writer who published any regular treatises on comparative anatomy and physiology, and his works on these subjects may be still read with much interest after all the additions which have been made to them by the moderns.* But notwithstanding all these favourable circumstances, it may be questioned whether the influence of Aristotle has not been ultimately somewhat unfavourable to the progress of knowledge. With his valuable facts and observations he mixed up a large portion of recondite and refined speculations, so that it is frequently not easy to separate the one from the other; and so great was the ascendancy which this genius acquired over the minds of men for many centuries after his death, that all his opinions, the most unfounded as well as the most philosophical, were indiscriminately received as established truths, which no one ventured to oppose or to controvert.†

The next circumstance which we are called upon to notice in the history of medicine is the establishment of the school of Alexandria. This was effected by the munificence of the Ptolemics, who, about three hundred years before the Christian era, laid the foundation of the celebrated Alexandrian library and of the school of philosophy which is graced by so many illustrious names. The science of medicine was cultivated in this school with peculiar assiduity, and we owe some very essential improvements to its professors. Among the most famous of these are Erasistratus and Herophilus. We have not much accurate information respecting the personal history of these two individuals, nor have any of their works been transmitted to us; but we have a detailed account of their opinions and practice given us by Galen, Cœlius Aurelianus, and others, so as to enable us to form a tolerably correct estimate of their merits. They are particularly mentioned as being the first who dissected the human subject, for which purpose the bodies of criminals were allotted to them by the government; and it appears that they amply profited by the advantage which was thus given them, so as very considerably to advance our knowledge of the structure of the body, especially by pointing out those circumstances in which the human subject differed from that of the animals who most nearly resembled it, and in correcting the errors on this point into which their predecessors had fallen. Nearly every part of the great system of which the body is composed profited by their labours: they ascertained with much more correctness than had been previously done the structure of the heart and great vessels, and of the brain and nerves, and they even seem to have had some imperfect knowledge of the absorbents. We are informed that Erasistratus was the pupil of Chrysippus, and that he imbibed from him his prejudice against bleeding and against the use of active remedies, trusting more to the operation of diet or the natural efforts of the system: hence we are to regard him as having improved the practice of medicine only indirectly by the addition which he made to our knowledge of anatomy.‡ The anatomical fame of Herophilus is so intimately blended with that of Erasistratus that we are unable to assign to each his respective share of merit; but it would appear that the former was more correct and more skilful in the practical department. Of this we have one proof in the fact which is stated by Galen, that Herophilus was one of the first who paid very minute attention to the varieties of the pulse; and his name is handed down to us by the ancients as entitled to the highest respect, both from his character and his acquirements.§

An important circumstance in the history of medicine, and more especially in that department to which our attention is particularly directed, occurred soon after the establishment of the Alexandrian school, viz. the division into distinct professions, which were exercised by different individuals. Previously to this period the practice of what is more especially styled medicine and of surgery was exercised by the same person; the *iarpog* of the Greeks corresponding nearly to what we

should now term the general practitioner. But about this time the separation into the departments of dietetics, pharmacy, and surgery commenced, and was gradually admitted into all succeeding schools or sects. The terms did not, however, possess precisely the same signification as in modern times. Dietetics comprehended not the regulation of the diet alone, but every circumstance connected with the general health or management of the patient, and corresponded very nearly to the "medicus" or physician of modern times. The second included not merely the department of the apothecary or the compounder of drugs, but the performance of many of the operations of surgery; while to the third was allotted the treatment of surgical diseases, many of the operations, however, being committed to the professors of the second branch. That this separation eventually tended to the improvement of the respective branches of the profession will scarcely be doubted, although it must at the same time be acknowledged that many of the distinctions which were introduced were frivolous and invidious, and are now rapidly yielding to the superior intelligence of modern times.*

It was about this period, *i. e.* shortly after the establishment of the Alexandrian school, that the great schism, to which we have so often alluded, took place. It was occasioned by the formation of the rival sects of the Dogmatists and the Empirics. Neither of these terms, in the first instance, bore exactly the same meaning which they convey to a modern ear. The controversy really consisted in the question, how far we are to suffer theory to influence our practice. While the Dogmatists, or, as they were sometimes styled, the Rationalists, asserted that before attempting to treat any disease we ought to make ourselves fully acquainted with the nature and functions of the part which is affected, or rather of the body generally, with the operation of medical agents upon it, and with the changes which it undergoes when under the operation of any morbid cause; the Empirics, on the contrary, contended that this knowledge is impossible to be obtained, and, if possible, is not necessary;—that the minute and internal changes of the system, and of its different parts, are beyond the reach of our most acute observation, that it is alone essential to watch the phenomena of disease, and to discover what remedies are best fitted to relieve the morbid symptoms;—that our sole guide must be experience; and that, if we step beyond this, either as derived from our own experience or observation, or that of others on whose testimony we can rely, we are always liable to fall into dangerous and often fatal errors. We may remark that this controversy, like so many others which have occupied the attention of mankind for a succession of ages, is partly verbal, and in so far as it is not verbal, that it is a question of degree. The boldest Dogmatist professes to build his theory upon facts, and the strictest Empiric cannot combine his facts without some aid from theory. The uniform experience of all the schools and sects from the days of Hippocrates to the present time, demonstrates that the undue extension of either of these systems is injurious, that they both originate from a partial view of the subject, and may generally be traced to some defect either in the acquired information or natural disposition of the practitioner. The controversy, however, forms so prominent a feature in the history of medicine, that it will be necessary to advert to it very frequently in the following pages; and we shall find that in estimating the value of the various opinions or modes of practice which will successively pass under our review, it will in most cases be necessary to inquire from which of these sects they emanated.†

Respecting the individuals to whom the origin of these sects should be referred, there is some degree of obscurity: the Dogmatists generally claim Hippocrates for their founder, and it is certain that he investigated with great care the functions of the animal body, the action of morbid causes upon it, and the operation of remedies, or, as we should style them, the general principles of pathology and therapeutics. But while in this respect he acted upon the principles of the Dogmatists, he was no less remarkable for the accuracy with which he observed the phenomena of disease, and the actual operation of remedies upon individual cases, or even upon particular symptoms; and it may be affirmed, that in most instances, when his preconceived hypothesis seemed to be in contradiction to the results of his experience, he wisely followed the latter. We may, however, easily imagine

* *Celsus*, lib. i. pr. f. *Schulz*, p. ii. cap. 5. *Le Clerc*, par. i. liv. ii. ch. 9. *Eloy*, "Partage de la Médecine."

† For an elegant summary of the arguments employed in this controversy, the reader is referred to *Percival's Essays*, nos. 1 and 2.

that his successors, not being possessed of his sagacity and industry, would prefer the easier method of indiscriminately adopting all his principles and speculations, to the more arduous task of correcting or extending them by their own observation, and that they would in this way bring all theoretical reasoning into disrepute. It is more probable that this feeling would be gradually induced in the minds of practitioners, than that it would be at once announced by any single individual; and as a matter of historical fact, the ancients themselves were divided in their opinion as to the person to whom they should ascribe the origin of the empirical sect. Pliny attributes it to Acron, a physician of Sicily,* who was contemporary, if not prior to Hippocrates; while Celsus states that Serapion of Alexandria, who was said to be a pupil of Herophilus, was the first who distinctly professed the opinion that theory is to be totally discarded in medicine, and that direct experience should be our sole guide.† We have little correct information respecting either the history or the practice of Serapion; none of his writings have been transmitted to us, but from the scattered notices which we meet with concerning him, dispersed through the works of the ancients, it may be conjectured that he was a man of considerable acuteness and sagacity, and that he generally adopted the practice of Hippocrates and his school, although he discarded their theory.‡

All the medical men of the period at which we are now arrived, and for some centuries subsequent to it, were attached to one or other of these rival sects, and, it would appear, in nearly an equal proportion. Unfortunately, however, for the Empirics, it has happened that all their writings have perished, so that we are obliged to form our opinion of their merits principally from the representation of their antagonists. There is, indeed, one happy exception in the works of Celsus, who, in the commencement of his treatise, has given an account of the leading opinions of the two opposing sects, in so candid and judicious a manner as almost to supersede any more elaborate discussion. It has been thought by many that the view which Celsus gives of the controversy is too favourable to the Empirics; and we admit that we can scarcely read his account without being impressed with the opinion, that he advocates their side of the question. Yet the conclusion which he draws is perfectly candid, and is, indeed, not very remote from what the most enlightened practitioner would form at the present day;—that the perfect rule of practice is derived from a due combination of reason and experience; that without experience all preconceived theory would be vain and useless; and that by simple experience, without any attempt at generalization, we should frequently fall into gross errors, and be unable to profit even by the very experience which is so much extolled. And, indeed, whatever may have been the professed plan of the supporters of the two sects, we shall always find that the practice of the most eminent of either party actually proceeded upon a judicious combination of the two systems; and we are now persuaded that it is upon such a combination that all further improvements of the science and practice of medicine must essentially depend.§

CHAPTER IV.

On the State of Medicine among the Romans from its first Introduction into Rome until the Time of Galen—Roman Superstitions—Archagathus—Cato—Asclepiades—Themison—Origin of the Methodist Sect—Thessalus—Soranus—C. Aurelianus—Doctrines of the Methodics—Pneumatics and Eclectics—Aretæus—Archigenes—Celsus, his Doctrines and Practice—Condition of Physicians in Rome—Pliny—Dioscorides.*

For some centuries the school of Alexandria produced a succession of learned men, not only in medicine but in the other sciences, and contributed to the advancement of knowledge, or at least prevented the decay into which it was in danger of falling after the decline of the Grecian literature. It was during this period that the foundation was laid of the future grandeur of the Roman empire; but from the attention of this people being almost exclusively directed to warlike affairs, and perhaps also from other causes, science of all kinds, and medicine among the rest, was for a long time almost totally neglected. Rome had extended her empire far beyond the limits of Italy, and had subdued most of her rivals, before she condescended even to tolerate the pursuit of the arts and sciences. We are expressly told by Pliny, that for six hundred years she was without physicians. We cannot conceive it possible that during this long period no attempts were made to remove diseases; we can only understand by it that there were no individuals eminent for their knowledge or skill who were engaged in the profession, or perhaps that it was scarcely regarded as the object of distinct pursuit, or that individuals were not especially trained to the exercise of it. We have, indeed, abundant evidence of two circumstances; that in this, as in every other subject connected with the arts of life, the Romans servilely copied from the Greeks,† and that, as far as their medicine was concerned, wherever they deviated from them it was for the purpose of adopting various superstitious rites and ceremonies, indicating the most profound ignorance and the grossest superstition. Numerous instances of this kind are incidentally mentioned by Livy; and although he wrote in the refined age and splendid court of Augustus, they are introduced in the thread of his narrative as actual transactions, without any observation indicative of his disbelief of their efficacy.‡ One of these is the account which he gives us of the introduction of the worship of Æsculapius into Rome. In consequence of a fatal epidemic, the senate had recourse to the usual expedient of consulting the Sibylline books, where it was found to be enjoined upon them to transfer the worship of the god from Greece to their city. A formal deputation was accordingly despatched for the purpose, by whom the deity, unwilling to leave his native place, was seized by a stratagem, and was conveyed under the form of a serpent into Italy. He was received by the people of Rome with unbounded transport; a temple was erected to him on an island in the Tiber; the usual appendages of priests, with all their ceremonies, were appointed; and the plague was of course suspended.§

Pliny further informs us that medicine was introduced into Rome at a later period than most of the other arts and sciences; that the practice of it had even been expressly prohibited by the citizens, and its professors banished. The

* For a concise, and at the same time a comprehensive, view of this period of the history of medicine, the reader is referred to the fifth section of Blumenbach's Introduction. I may further remark that this work may be consulted with advantage, in connection with almost all the names that pass in succession under our review.

† Suetonius, de Grammat. sub initio; the fact is admitted by Cicero and by Pliny, and is frequently alluded to in various parts of their writings.

‡ The following references may be selected among many others of a similar kind:—Book i. ch. 31, Tullius consults the Sibylline books in order to stop the plague;—iv. 25, for the same purpose a temple is erected to Apollo;—v. 13, the books were again consulted;—vii. 2, a lectisternium was ordered for the same purpose, and afterward the public games;—vii. 3, the plague was stopped by the dictator driving a nail.

§ Livius, lib. x. cap. 47, et epitome ad lib. xi. Val. Maximus, lib. i. cap. 8. §. 2. Schulz, p. ii. cap. 6. §. 4 et seq. Montfaucon, Antiq. Suppl. v. i. b. v. ch. 1. Lucianus, Tooke's Trans. v. i. p. 635, note.

account which he gives of so singular an occurrence is, that about two hundred years before Christ, Archagathus, a Peloponnesian, settled at Rome as a practitioner of medicine, and, as it may be inferred, was the first person who made it a distinct profession. He was received in the first instance with great respect, and was even maintained at the public expense; but his practice was observed to be so severe and unsuccessful, that he soon excited the dislike of the people at large, and produced a complete disgust to the profession generally, which led to the transaction mentioned above.* His practice seems to have been almost exclusively surgical, and to have consisted, in a great measure, in the use of the knife and of powerful caustic applications. We hear little more of the state of medicine in Rome for the next century; but from certain incidental observations we may infer that it remained principally in the hands of the priests, and consisted as before in superstitious rites and ceremonies. It appears, indeed, that the few individuals who devoted themselves to the cultivation of natural science, among other subjects directed their attention to medicine; and it is particularly stated that Cato introduced various articles into the *materia medica*, and wrote several treatises on medical topics. We are not able to form any just conception of their merit from the account which is given of them; but it is worthy of remark that he was a professed opponent to Grecian literature in general, and we may therefore conclude, would not avail himself of the improvements that had been made by the Greek physicians.†

We may presume that the prejudice which was excited against Archagathus would be gradually allayed, and that the improvement of the Romans in intellectual cultivation, although not considerable, would be at least sufficient to make them sensible of the necessity of attempting something beyond the mere power of charms and incantations for the removal of disease. Accordingly, about a century before the Christian era, we find that another individual had acquired a very considerable degree of popularity at Rome, which he maintained through life, and in a certain degree transmitted to his successors,—Asclepiades of Bithynia. It is said that he first came to Rome as a teacher of rhetoric, and that it was in consequence of his not being successful in his profession that he turned his attention to the study of medicine. From what we learn of his history and of his practice, it would appear that he may be fairly characterized as a man of natural talents, acquainted with human nature, or rather with human weakness, and possessed of considerable shrewdness and address, but with little science or professional skill. He began upon the plan which is so generally found successful by those who are conscious of their own ignorance, of vilifying the principles and practice of his predecessors, and of asserting that he had discovered a more compendious and effective mode of treating diseases than had been before known to the world. As he was ignorant of anatomy and pathology, he decried the labours of those who sought to investigate the structure of the body, or to watch the phenomena of disease, and he is said to have directed his attacks more particularly against the writings of Hippocrates. It appears, however, that he had the discretion to refrain from the use of very active and powerful remedies, and to trust principally to the efficacy of diet, exercise, bathing, and other circumstances of this nature. A part of the great popularity which he enjoyed depended upon his prescribing the liberal use of wine to his patients, and upon his attending in all cases, with great assiduity, not only to every thing which contributed to their comfort, but that he flattered their prejudices and indulged their inclinations. By the due application of these means, and from the state of the people among whom he practised, we may, without much difficulty, account for the great eminence to which he arrived, and we cannot fail to recognise in Asclepiades the prototype of more than one popular physician of modern times.

Justice, however, obliges us to admit that he seems to have been possessed of a considerable share of acuteness and discernment, which on some occasions he employed with advantage. It is said that to him we are indebted, in the first instance, for the arrangement of diseases into the two great classes of acute and chronic, a division which has a real foundation in nature, and which still forms an important feature in the most improved modern nosology. In his philosophical principles Asclepiades is said to have been a follower of Epicurus, and to have adopted

* Lib. xxix. cap. 1.

† *Le Clerc*, par. ii. liv. iii. ch. 1. *Schulz*, p. ii. cap. 6. *Ackermann*, p. iv. cap. 15.

his doctrine of atoms and pores, on which he attempted to build a new theory of disease, by supposing that all morbid action might be reduced into obstruction of the pores and irregular distribution of the atoms. This theory he accommodated to his division of diseases,—the acute being supposed to depend essentially upon a constriction of the pores, or an obstruction of them by a superfluity of atoms; the chronic, upon a relaxation of the pores or a deficiency of the atoms.*

Asclepiades was succeeded in his professional reputation by his pupil Themison of Laodicea, who had the honour of founding a new sect in medicine, which for some time almost eclipsed the former rivals; this was the Methodic sect. The great object of Themison seems to have been to adopt a middle course between the Dogmatists and the Empirics, and to take advantage of the excellences of each of them. He was, however, strongly impressed with the great principles of Asclepiades, the importance of reducing the science to a few general laws, which by their simplicity might be universally intelligible and of easy application. He therefore rejected all the abstruse and recondite speculations of the Dogmatists, and substituted in their place a few positions derived from the tenets of his master, and founded upon the Epicurean doctrines. He remarks that it is an essential part of the business of the practitioner to make himself acquainted with the nature of the human frame, with its laws while in the state of health, and with the changes which they experience from disease. All these he referred to the respective states of constriction and relaxation, and to the undue preponderance of one of them over the other. To these two, however, he added a third, or mixed state, as he styled it, the nature of which is not very easy to understand; while by classing all medical agents under the two great divisions of astringents and relaxants, we learn how to apply the appropriate remedy for every disease.

Themison's doctrine must be regarded as a refinement, and certainly an improvement of that of Asclepiades; for although we have the states of constriction and relaxation professedly copied from his master, it is disencumbered of the more objectionable speculation of the atoms and pores. The theory of the Methodics contemplates the solids as the seat and cause of disease, in which respect it is directly opposed to that of Hippocrates, who traced the primary cause of disease to an affection of the fluids, giving rise to what has been termed the Humoral Pathology. The humoral pathology was zealously defended by Galen, and was universally adopted by his successors until the seventeenth century, when the opposite doctrine of Solidism was revived, and has been gaining ground until the present day. It has been justly objected to Themison's theory, that even if we admit the correctness of his views respecting the states of constriction and relaxation of the system, there is a palpable absurdity in supposing that they can co-exist in what he terms his middle state, as they are directly opposed to each other.

There is no work of Themison's extant, but we have an ample account of his practice in the writings of Cælius Aurelianus, who was a zealous defender of the tenets of the Methodic sect. They appear to have been diligent in the observation of the phenomena of disease, and sagacious in their employment of remedies: they seem, indeed, to have sustained their character, of keeping a middle course between the Dogmatists and Empirics, avoiding the extremes of either, and combining the more useful parts of each system in a greater degree than had been done by their predecessors.†

For some time after the death of Themison the opinions of the Methodics were generally adopted in Rome, and almost superseded those of the professed Dogmatists and Empirics, so that we shall have little to detain us in our progress, except to notice certain individuals who became remarkable from their personal history or character, or from some peculiarity in their opinions or practice. The first of this description in point of time is Thessalus, who lived about half a century after Themison, and who ranks as one of his followers. He was, however, an individual very different, both in character and in acquirements, from his master. He is stated to have been of mean birth and of defective education, but, by cun-

* *Plinius*, passim. *Celsus*, ubi supra et alibi. *Le Clerc*, par. ii. liv. iii. ch. 4-9. *Sprengel*, sect. 5. ch. 1. *Cabanis*, ch. 2. §. 5. *Goulon*, *Encyc. Méth.*, Médecine, "Asclépiade." *Chaussier et Adelon*, in *Biog. Univ.*, "Asclépiade."

† *Celsus*, in præf. *Le Clerc*, p. ii. liv. iv. sect. 1. ch. 1. *Barchusen*, *Diss.* 11. *Sprengel*, t. ii. p. 20-3. *Ackermann*, per. iv. ch. 17.

ning and artifice, to have acquired great wealth and a high reputation. He began his career, in the usual mode of ignorance and self-sufficiency, by endeavouring to throw contempt on all his predecessors and contemporaries, by pretending to expose their errors, and by claiming to himself the discovery of a new theory of medicine which should lead to more correct practice, and should supersede all further attempts of the kind; in fine, he assumed to himself the pompous title of the conqueror of physicians (*ιατρονικης*).*

We shall not have occasion to dwell long upon one who is so unworthy of a place in the records of science; it is only necessary to remark concerning him, that he appears to have united the speculations of Asclepiades with those of Themison, and to have admitted the atoms and pores of the one, with the constriction and relaxation of the other. The only addition which Thessalus made to medical theory which deserves our notice, is the introduction of what he terms *metasyncrasis*, or the method of producing an entire change in the state of the body. This he opposed to the practice of Hippocrates, who professed to watch over and regulate the actions of the system, as well as to that of the Empirics, whose aim was to correct specific morbid actions, or to remove particular morbid symptoms. The term, as conveying a conceivable if not an actual occurrence, was not without its value, and was generally adopted by medical writers; and even in the present day the principle implied in it serves as the foundation for some of our most important indications.†

The name of Soranus next occurs among the celebrated Roman practitioners. There is, indeed, some reason for supposing that there were no less than three physicians of this name, but the one who is most eminent appears to have been a native of Ephesus, to have studied at Alexandria, and finally to have settled in Rome. He was a strict Methodic, and is said to have been highly respected for his character and talents. His writings have not been transmitted to us, but probably the most valuable information which they contain is handed down to us by C. Aurelianus, whose work, if not, as some have supposed, a translation of Soranus's treatise, proceeds upon the same principles, and inculcates the same practice.‡

There is considerable uncertainty respecting both the age and country of C. Aurelianus. Some writers place him as early as the first century of the Christian era, while others endeavour to prove that he was at least a century later. This opinion is principally founded upon the circumstance of his not mentioning or being mentioned by Galen, indicating that they were contemporaries or rivals. Numidia has been generally assigned as his native country, but perhaps without any direct evidence; it may, however, be concluded from the imperfection of his style, and the incorrectness of some of the terms which he employs, that he was not a native either of Greece or of Italy. But whatever doubts may attach to his personal history, and whatever defects exist in his writings, they afford us much valuable information respecting the state of medical science. He was a professed and zealous Methodic, and it is principally from his work that we are able to obtain a correct view of the principles and practice of this sect. In his descriptions of the phenomena of disease he displays considerable accuracy of observation and diagnostic sagacity; and he describes some diseases which are not to be met with in any other ancient author. He gives us a very ample and minute detail of the practice which was adopted both by himself and his contemporaries; and it must be acknowledged that on these points his remarks display a competent knowledge of his subject, united to a clear and comprehensive judgment.

He divides diseases into the two great classes of acute and chronic, nearly corresponding to diseases of constriction and of relaxation, and upon these supposed states he founds his primary indications; but with respect to the intimate nature of these states of the system, as well as of all hidden or recondite causes generally, he thinks it unnecessary to inquire, provided we can recognise their existence, and can discover the means of removing them. Hence his writings are less theoretical and more decidedly practical than those of any other author of an-

* *Plinius*, lib. xxix. cap. 1.—We have an amusing, and probably a correct, account given us by Lucian, of the successful knavery practised by an impostor of his age, named Alexander; see Tooke's *Trans.*, v. i. p. 630 et seq. He appears to have been a worthy successor of Thessalus, so far as respects his arrogance and presumption.

† *Le Clerc*, p. ii. liv. iv. sect. 1, ch. 2, 3. *Sprengel*, t. ii. p. 28-31.

‡ *Le Clerc*, par. ii. liv. sect. 1, ch. 4. *Sprengel*, t. ii. p. 33-5.

tiquity; and they consequently contributed more to the advancement of the knowledge and actual treatment of disease than any that had preceded them. They contributed in an especial manner to perfect the knowledge of therapeutics, by ascertaining with precision the proper indications of cure, with the means best adapted for fulfilling them. The great defect of C. Aurelianus, a defect which was inherent in the sect to which he belonged, was that of placing too much dependence upon the twofold division of diseases, and not sufficiently attending to the minute shades by which they gradually run into each other; a defect the more remarkable in one who shows so much attention to the phenomena of disease, and who, for the most part, allows himself to be so little warped by preconceived hypothesis. This view of the subject leads him not unfrequently to reject active and decisive remedies, when he could not reconcile their operation to his supposed indications; so that, although his practice is seldom what can be styled bad, it is occasionally defective.

There were two points in which C. Aurelianus, and the Methodics generally, decidedly opposed the doctrines and practice of the followers of Hippocrates, in trusting the removal of disease to the restorative powers of nature, and in attributing diseases to the excess or defect of particular humours. With respect to the former point, they conceived that it was as frequently necessary to oppose as to promote the natural actions of the system; and with respect to the latter, they did not admit the existence of the supposed four humours; and even, if their existence could be proved, they did not conceive that they were in possession of the means of acting upon them individually or specifically.

In the treatment of acute diseases, or those of constriction, the cure was effected by topical bleeding (for general bleeding was rarely admitted), and by narcotic and oleaginous applications, aided by a pure and sometimes by a moist air. Abstinence was strictly enjoined, and indeed often carried to an undue length; and in the administration of all remedies the practitioner was frequently guided by critical periods, generally of three, or in other cases of seven days. When the ordinary means of cure were found not to be successful, or when any circumstance occurred which appeared to contra-indicate their application, C. Aurelianus had recourse to a preparatory system. This consisted principally in certain regulations regarding diet and exercise, in the use of the bath, frictions, and other external applications; when the system was thus prepared, the ordinary plan of treatment was had recourse to. Inflammatory diseases were supposed to depend upon constriction; abstinence, rest, and friction were enjoined in the first instance; bleeding, general or local, baths, and certain vegetable preparations were then administered, while purgatives seem to have been seldom if ever employed. Little regard appears to have been paid to particular symptoms, and upon the whole we should be disposed to consider the practice as deficient in promptness and vigour, and not very unlike that which prevails at this day in many parts of the Continent. We have mentioned above that C. Aurelianus seldom employed purgatives,—an unfortunate prejudice, by which he deprived himself of one of the most useful agents in the cure of disease; he also generally condemns the use of what are termed specifics,—an error, if it be one, much more venial; he very sparingly employs diuretics, condemns narcotics, and rejects caustics and all similar applications.*

Although the Methodic sect continued to prevail among the Roman physicians during the greatest part of the first two centuries of the Christian era, some alteration in the original tenets of Themison were gradually introduced, and it at length became subdivided into several minor sects or schools, which, although agreeing in certain fundamental principles, had each their peculiar views, which led to their separation from the main body, and to the adoption of specific appellations. Two of these were of sufficient notoriety to require being individually mentioned in this sketch,—the Pneumatics, and the Eclectics or Episynthetics.

The Pneumatics rose into notice about half a century after the death of Themison. They derive their appellation from the circumstance of their having introduced into their pathology the agency of what is termed the spirits (*πνεύμα*), which, together with the solids and fluids, compose the corporeal frame. It would be somewhat difficult to state, in a few words, to what supposed substance or power

* Vide Opus, de Morb. Acut et Chron. *Le Clerc*, par. ii. liv. iv. sect. 1, ch. 5–11; we have in this author a very ample account of the principles and practice of the Methodics. *Barchusen*, Diss. 11, §. 5. *Haller*, Bib. Med. §. 72. *Sprengel*, t. ii. p. 37 et seq. *Eloy*, in loco. *Biog Univ.* in loco.

the term was applied; we may observe in it some traces of the pneumatic physiology of the modern chymists, while in some of its agencies it resembles the nervous influence. This sect has acquired considerable celebrity from the name of an eminent medical writer, which has been generally attached to it, that of Aretæus.

There is some uncertainty respecting both the age and the country of Aretæus; but it seems probable that he practised in the reign of Vespasian, and he is usually styled the Cappadocian. He wrote a general treatise on diseases, which is still extant, and is certainly one of the most valuable reliques of antiquity, displaying great accuracy in the detail of symptoms, and in seizing the diagnostic character of diseases. In his practice he follows, for the most part, the method of Hippocrates, but he paid less attention to what have been styled the natural actions of the system; and, contrary to the practice of the father of medicine, he did not hesitate to attempt to counteract them, when they appeared to him to be injurious. The account which he gives of his treatment of various diseases indicates a simple and sagacious system, and one of more energy than that of the professed Methodics. Thus he freely administered active purgatives; he did not object to narcotics; he was much less averse to bleeding; and upon the whole his *materia medica* was both ample and efficient. It may be asserted generally, that there are few of the ancient physicians, since the time of Hippocrates, who appear to have been less biased by attachment to any peculiar set of opinions, and whose account of the phenomena and treatment of disease has better stood the test of subsequent experience. We have placed Aretæus among the Pneumatics, because he maintained the doctrines which are peculiar to this sect, and because he is generally considered as such by most systematic writers, although perhaps, strictly speaking, he is better entitled to be placed with the Eclectics.*

Of the sect of the Eclectics we know little except through the medium of the writings of their opponents. The most celebrated of them was Archigenes of Appamea, who practised at Rome in the time of Trajan, and enjoyed a very high reputation for his professional skill. He is, however, reprobated as having been fond of introducing new and obscure terms into the science, and having attempted to give to medical writings a dialectic form, which produced rather the appearance than the reality of accuracy. Archigenes published a treatise on the pulse, on which Galen has written a commentary; it appears to have contained a number of minute and subtle distinctions, many of which we may venture to affirm have no real existence, and to have been, for the most part, the result rather of a preconceived hypothesis than of actual observation; and the same remark may be applied to an arrangement which he proposed of fevers. He, however, not only enjoyed a considerable degree of the public confidence during his lifetime, but left behind him a number of disciples, who for many years maintained a respectable rank in their profession.†

It may appear singular that we have so many instances of individuals who have risen to great eminence, both from their professional skill and general science, but of whose private history we possess so little information. This is very remarkably the case with Celsus. We know little of his age, his origin, or even of his actual profession. There are some incidental expressions which lead to the conjecture that he lived under the reigns of Augustus and Tiberius, and particularly the mode in which he refers to Themison would indicate that they were either contemporaries, or that Themison preceded him by a short period only. With respect to the country of Celsus we have nothing on which to ground our opinion, except the purity of his style, which at most would prove no more than that he had been educated, and passed a considerable part of his life at Rome.

With regard to his profession, it has been doubted whether he was a practitioner of medicine, or whether he only studied it as a branch of general science after the manner of some of the ancient Greek philosophers. This doubt has arisen principally from the mode in which he is referred to by Columella‡ and by Quintilian,§ and by his not being enumerated by Pliny among the physicians of Rome in his

sketch of the history of medicine. Yet, on the other hand, it appears to me that his work bears very strong evidence that he was an actual practitioner, that he was familiar with the phenomena of disease and the operation of remedies, and that he described and recommended what fell under his own observation, and was sanctioned by his own experience; so that I conceive it, upon the whole, most probable that he was a physician by profession, but who devoted part of his time and attention to the cultivation of literature and general science.

The treatise of Celsus "On Medicine" is divided into eight books. It commences by a judicious sketch of the history of medicine, terminating by the comparison of the two rival sects, the Dogmatists and the Empirics, which has been referred to above. The two next books are principally occupied by the consideration of diet, and the general principles of therapeutics and pathology: the remaining books are devoted to the consideration of particular diseases and their treatment, the third and fourth to internal diseases, the fifth and sixth to external diseases and to pharmaceutical preparations, and the two last to those diseases which more particularly belong to surgery. In the treatment of disease, he for the most part pursues the method of Aselepiades; he is not, however, servilely attached to him, and never hesitates to adopt any practice or opinion, however contrary to his, which he conceived to be sanctioned by direct experience. He adopted, to a certain extent, the Hippocratic method of observing and watching over the operations of nature, and rather regulating than opposing them, a method which, with respect to acute diseases, may frequently appear inert. But there are occasions on which he displays considerable decision and boldness, and particularly in the use of the lancet, which he employed with more freedom than any of his predecessors. His regulations for the employment of bloodletting and of purgatives are laid down with minuteness and precision; and although he was, in some measure, led astray by his hypothesis of the crudity and concoction of the humours, the rules which he prescribed were not very different from those which were generally adopted in the commencement of the present century. His description of the symptoms of fever, and of the different varieties which it assumes, either from the nature of the epidemic, or from the circumstances under which it takes place, are correct and judicious; his practice was founded upon the principle so often referred to, of watching the operations of nature, conceiving that fever consists essentially in an effort of the constitution to throw off some morbid cause, and that, if not unduly interfered with, the process would terminate in a state of health. We here see the germ of the doctrine of the *vis medicatrix nature*, which has had so much influence over the practice of the most enlightened physicians of modern times, and which, although erroneous, has perhaps led to a less hazardous practice than the hypotheses which have been substituted in its room.

But perhaps the most curious and interesting parts of the work of Celsus are those which treat of surgery and surgical operations. It is very remarkable that he is almost the first writer who professedly treats on these topics, and yet his descriptions of the diseases and of their treatment prove that the art had attained to a very considerable degree of perfection. Many of what are termed the capital operations seem to have been well understood and frequently practised, and we may safely assert, that the state of surgery, at the time when Celsus wrote, was comparatively much more advanced than that of medicine. The pharmacy of Celsus forms another curious and interesting part of his work, and, like his surgery, marks a state of considerable improvement in this branch of the art. Many of his formulæ are well arranged and efficacious, and on the whole they may be said to be more correct, and even more scientific, than the multifarious compounds which were afterward introduced into practice, and which were not completely discarded until our own times.*

There is one circumstance respecting Celsus which requires to be noticed, that he is the first native Roman physician whose name has been transmitted to us. Before his time all those who arrived at any degree of eminence were either Greeks or Asiatics, and it would appear that the native practitioners were either slaves or persons from the lower ranks of life, who acted in the subordinate branches

* *Le Clerc*, par. 2. liv. iv. sect. 2, ch. 4, 5. *Barchusen*, diss. 15, p. 231, 2. *Morgagni*, *Epistolæ* in *Celsum*. *Haller*, *Bib. Med.* t. i. §. 49. *Eloy*, in loco. *Nouv. Dict. Hist.* in loco. *Sprengel*, t. ii. p. 25-8. *Black's Hist. of Medicine*, p. 63-82. *Goulin*, *Encyc. Méth. Médecine*, in loco. *Petit-Radel*, *Biog. Univ.* "Celse."

of the profession.* This circumstance may be attributed partly to the low state of science in Rome, even during the period when literature had advanced to a considerable eminence, and still more to the idea of degradation or servility which seems to have been attached to the exercise of any art or profession for the sake of gain. All the trades and manufactures of Rome were therefore carried on by slaves, and medicine seems to have been placed in the same class. It must, however, be observed, that many individuals who were brought to Rome as slaves, either by their natural talents or by some favourable conjuncture of circumstances, overcame the disadvantages of their situation, and made considerable acquirements in different departments of knowledge, and among others in that of medicine. One of the most celebrated of these is Antonius Musa, who was appointed physician to Augustus, and obtained great celebrity from his practical skill: we are told that he was a pupil of Themison, and it appears that he remained attached to the Methodic sect.†

Before we close this part of our history, it will be necessary to take some notice of a class of writers, whose names or works are transmitted to us, who particularly devoted themselves to the improvement of pharmacy. The first of these was Scribonius Largus, who flourished in the reign of Claudius. He appears to have been, like Musa, originally a slave, and it may be conjectured from his work "On the Composition of Medicines," which has been transmitted to us, that he was never able to supply the deficiency of his education. It is a mere collection of nostrums and formulæ, without arrangement or discrimination, and is solely valuable as indicating the state of the art at the time of its publication.‡

Andromachus, a native of Crete, who lived under the reign of Nero, is principally known to posterity as the inventor of certain compounded pharmaceutical preparations, one of which, the theriaca, obtained so much celebrity as to have been retained in our pharmacopœia until the close of the last century. It was composed of no less than sixty-one ingredients, which were combined together with much ceremony and no inconsiderable degree of labour and skill. Its essential ingredient, from which it derived its name, was the dried flesh of vipers, against the bites of which animals it was supposed to be an antidote. But its supposed medical virtues were equal to the number of articles of which it consisted, so that there was scarcely a disease for which the theriaca of Andromachus has not been proposed as a remedy. Andromachus is further remarkable as being the first individual on whom the title of Archiater, or principal physician, was bestowed by the emperors—a title which was continued for several centuries.§

We have next to notice an author of just celebrity, whose writings form one of the most valuable remains of antiquity,—Pliny the naturalist. Although not attached to the medical profession, and even, as appears from many of his remarks, by no means favourably disposed to it, in various parts of his great work he affords us much important information, both direct and indirect, respecting the history of medicine in all its branches, and more especially in all that concerns materia medica and pharmacy.|| We meet with a great number of curious facts and remarks upon these subjects, so that we are enabled from them to form a tolerably complete conception of the state of medical science in the age in which he wrote. We learn from his works that the ordinary practice was, in a considerable degree, what may be termed empirical, consisting in the application of certain remedies for certain diseases, without any inquiry into their mode of operation. The materia medica, which was extensive, consisted principally of vegetable products, and these combined together in various forms, but without any regard to what we should now regard as scientific principles, either chymical or pharmaceutical. We find that they possessed various active remedies, adapted to the greatest part of the

* *Le Clerc*, par. 3. liv. i. ch. 2. The condition of the practitioners of Medicine in Rome was the subject of a learned controversy between Mead and Middleton; see *Life of Mead*, prefixed to his works, v. i. p. 13, Edin. 1765, and Aikin's *Gen. Biog.* art. "Middleton."

|| The late illustrious naturalist Cuvier has formed what I conceive to be a very just and candid estimate of the literary and philosophical character of Pliny, *Biog. Univ.* t. xxxv. in loco; the same inserted into the translation of Pliny by M. Aj. de Grandsagne, t. i. p. 85. See *Eloy*, in loco, for a list of the various editions, &c. of Pliny; he enumerates one hundred and ten, of which it is worthy of notice that two only were printed in England. *Haller*, *Bib. Bot.* t. i. p. 91-8.

most important indications, so far as they could be obtained from vegetable or animal substances, but that in the application of them they frequently proceeded upon incorrect principles.

Another writer who lived about the same time with Pliny, and who, although less distinguished for general science, holds a conspicuous rank among the medical authors of this period, is Dioscorides. The same obscurity hangs over every thing which regards the personal history of Dioscorides, as over that of so many individuals to whom we have had occasion to refer. It is generally supposed that he was a native of Asia Minor, and that he was a physician by profession. It appears pretty evident that he lived in the second century of the Christian era, and as he is not mentioned by Pliny, it has been supposed that he was a little posterior to him. The exact age of Dioscorides has, however, been a question of much critical discussion, and we have nothing but conjecture which can lead us to decide upon it. He has left behind him a treatise on the *materia medica*, a work of great labour and research, and which, for many ages, was received as a standard production. The greater correctness of modern science, and the new discoveries which have been made, cause it now to be regarded rather as a work of curiosity than of absolute utility; but in drawing up a history of the state and progress of medicine, it affords a most valuable document for our information. His treatise consists of a description of all the articles then used in medicine, with an account of their supposed virtues. The descriptions are brief, and not unfrequently so little characterized, as not to enable us to ascertain with any degree of accuracy to what they refer, while to the practical part of his work the same remark nearly applies, that was made above with respect to Pliny, that it is, in a great measure, empirical, although his general principles, as far as they can be detected, appear to be those of the Dogmatic sect. The great importance which was, for so long a period, attached to the works of Dioscorides has rendered them the subject of almost innumerable commentaries and criticisms, and even some of the most learned of our modern naturalists have not thought it an unworthy task to attempt the illustration of his *Materia Medica*. Upon the whole, we must attribute to him the merit of great industry and patient research, and it seems but just to ascribe a large portion of the errors and inaccuracies into which he has fallen, more to the imperfect state of science when he wrote than to any defect in the character and talents of the writer.*

CHAPTER V.

Account of the opinions and practice of Galen—His history and education—Remarks on his character and writings—His physiology, anatomy, pathology, and practice.

THE course of our narrative brings us to one of those extraordinary characters who are destined to form an era in the history of science, both from the actual improvements which they have introduced into it, and from the ascendancy which their genius enabled them to acquire over the minds of their contemporaries. Of these, one of the most remarkable that ever appeared, either in ancient or in modern times, is Galen. Galen enjoyed, both from birth and from education, every natural and acquired advantage; his father was a man of rank, and his education appears to have been conducted upon the most liberal and judicious plan. He studied philosophy in the various schools that were then in the highest estimation, and without exclusively attaching himself to any one of them, he is said to have taken from each what he conceived to be the most important parts of their systems, with the exception of the Epicurean, the tenets of which he entirely rejected. His professional studies were conducted upon an equally extensive plan; he attended

* *Le Clerc*, par. iii. liv. ii. ch. 2. *Eloy*, in loco, where we have an account of the various editions, comments, translations, &c. *Sprengel*, t. ii. p. 58-64. *Ackermann*, p. 4. cap. 19. *Haller*, Bib. Bot. t. i. p. 79-87. *Goulin*, Encyc. Méth. Médecine, "Dioscoride." *Du-Petit-Thouars*, Biog. Univ. in loco.

the various schools and travelled through different countries for the express purpose of acquiring information; but it may be presumed that his knowledge of medicine was principally acquired in Alexandria, which still retained its character as the great depository of medical science. After passing a few years at his native city of Pergamus, spending some time at Rome, and again at Pergamus, he finally returned to Rome, in consequence of the express request of the Emperor Aurelius, and made that city his residence for the remainder of his life.

The works which Galen left behind him are very numerous, amounting in the whole to about two hundred distinct treatises; they are all on subjects directly or indirectly connected with medicine, and exhibit a great extent of knowledge on the subjects of which he treats, and a degree of information, as far as we can judge, greater than that of any of his contemporaries. He appears also to have been a man of a superior mind and of a very decided character; confident in his own powers, and paying but little attention to the opinions of others. Hence he may be accused of arrogance and want of candour, and he can only be defended upon the principle that he was so far in advance of his contemporaries, as to be fully convinced of the futility of their reasoning and the deficiency of their information. The result was, that he gained that superiority over his contemporaries which he assumed, and actually acquired a sway over public opinion, on all points connected with medicine, which has never been obtained by any individual either before or since his time. The rank which Galen held in the medical world has been compared not unaptly to that which Aristotle possessed in the world of general science. For centuries after his death his doctrines and tenets were regarded almost in the light of oracles, which few persons had the courage to oppose; and all the improvements in medicine which were even contemplated, consisted of little more than illustrations of his doctrines or commentaries on his writings. In numberless instances it was deemed a sufficient argument, not merely against an hypothesis, but even against an alleged matter of fact, that it was contrary to the opinion of Galen; and it may be stated without exaggeration, that the authority of Galen alone was estimated at a much higher rate than that of all the medical writers combined, who flourished during a period of more than twelve centuries.

Although such a brilliant reputation might, in some measure, depend upon accidental circumstances, and upon the mere personal character of the individual, we may fairly presume that there must have been a foundation of a more solid nature: and upon an actual survey of the writings of Galen, we shall find ample reason to conclude that he was a man of great talents and of very extensive acquirements. In his general principles he may be considered as belonging to the Dogmatic sect, for his method was to reduce all his knowledge, as acquired by the observation of facts, to general theoretical principles. These principles he indeed professed to deduce from experience and observation, and we have abundant proofs of his diligence in collecting experience, and his accuracy in making observations. But still, in a certain sense at least, he regards individual facts and the detail of experience as of little value, unconnected with the principles which he laid down as the basis of all medical reasoning. In this fundamental point, therefore, the method pursued by Galen appears to have been directly the reverse of that which we now consider the correct method of scientific investigation; and yet, such is the force of natural genius, that, in most instances, he attained the ultimate object in view, although by an indirect path. He was an admirer of Hippocrates, and always speaks of him with the most profound respect, professing to act upon his principles, and to do little more than to expound his doctrines, and support them by new facts and observations. Yet in reality we have few writers whose works, both as to substance and manner, are more different from each other than those of Hippocrates and Galen, the simplicity of the former being strongly contrasted with the abstruseness and refinement of the latter. Those of his works which are the most truly valuable, and in which he actually rendered the greatest service to science are his treatises on physiology. The knowledge which he possessed on this subject was much more considerable than that of any of his contemporaries: in all that regards the operations of the animal economy he was much better acquainted with the facts, and much more ingenious in the application of them. He appears to have been well practised in anatomy, and especially in what may be termed pathological anatomy he far surpassed any of the ancients. His knowledge of particular structures was, in many respects, correct, and in his mode of classifying them he made no inconsiderable approach to the philosophical views which have been taken

of them by the anatomists of the present day. It appears upon the whole probable that he was not in the habit of dissecting the human subject, and, indeed, this may be fairly inferred from his own remarks; but there is reason to suppose that he omitted no opportunity of examining the structure of those animals which the most nearly resemble it, and that from them he has drawn up his descriptions. Considering this radical defect, it must be admitted that they possess great merit, and we may justly express our surprise at the few points in which they betray the imperfection of their origin.*

The pathology of Galen was much more imperfect than his physiology, for in this department he was left to follow the bent of his speculative genius almost without control. He adopts, as the foundation of his theory, the doctrine of the four elements, and like Hippocrates, he supposes that the fluids are the primary seat of disease. But in his application of this doctrine he introduced so many minute subdivisions and so much refined speculation, that he may be almost regarded as the inventor of the theory of the Humoralists, which was so generally adopted in the schools of medicine, and which, for so long a period, entirely engrossed their attention. The four elements, the four humours, and the four qualities, connected in all the variety of combinations, presented a specious appearance of method and arrangement, which took such firm possession of the mind as to preclude all inquiry into the validity of the foundation, and to present us with one of the most remarkable examples of the complete prostration of the understanding in a physical science, where facts were daily obtruding themselves upon our observation, but were either unnoticed or totally disregarded.

The practice of Galen in its general character appears to have been similar to his pathology, and, indeed, to have been strictly deduced from it. His indications were in exact conformity to his theory, and the operation of medicines was reduced to their power of correcting the morbid states of the fluids, as depending upon their four primary qualities or the various modifications of them. Many parts of his writings prove that he was a diligent observer of the phenomena of disease, and he possessed an acuteness of mind which well adapted him for seizing the most prominent features of a case, and tracing out the origin of the morbid affection. But his predilection for theory too frequently warped and biassed his judgment, so that he appears more anxious to reconcile his practice to his hypothesis than to his facts, and bestows much more labour on subtle and refined reasoning, than on the investigation of morbid actions, or the generalization of his actual experience.

The number of treatises which Galen left behind him is very considerable, amounting to nearly two hundred separate works, embracing every department of medical science. His style is generally elegant, but diffuse, and, as may be imagined from the multiplicity of his works, he frequently repeats and copies from himself. Considered under the two classes of anatomy and physiology, and of pathology and practice, the following may, perhaps, be selected as the most valuable, both with respect to the absolute addition which they made to the previous stock of knowledge, and as to the reasoning employed in them. Under the first head we may select the treatise "On the Use of the Parts of the Body," in seventeen books, in which he describes the structure of the different organs, and assigns to each of them its use. This is a work of great anatomical research and physiological ingenuity, which contains many facts that were probably the result of his own investigation, and exhibits a very favourable specimen of his reasoning powers, when not too much under the influence of preconceived hypothesis. The same kind of merit, although less in degree, may be assigned to the treatise "On the Motion of the Muscles," and also to that "On the Formation of the Fœtus," making due allowance for the greater difficulty and obscurity of the subject.

Among the works of the second class the treatise "On Temperaments" has been greatly and justly celebrated, as well as that "On the Seat of Disease," while that "On the Varieties of the Pulse" affords a happy illustration of his peculiar turn of mind, of his acuteness and originality, and, at the same time, of his devoted attachment to hypothesis. The two works, "On the Differences and the Causes of Diseases," and "The Method of Cure," are more especially interesting, as containing the most detailed view of his peculiar doctrines of the humoral pathology, of the indications of cure which he laid down, and the methods which he adopted for their accomplishment. These two latter works exhibit a very complete view of the

* Douglas, Bibliog. p. 18-22.

practice of Galen and of that of his contemporaries, and enable us to form a correct opinion of the state of the science when he entered upon the study of it, and of the additions which he made to it. To attempt an analysis of the works themselves, or of the details of Galen's practice, would carry me far beyond the limits of this treatise, and, indeed, it would be principally as a question of literary curiosity that such an examination could be sustained. Their general character may be understood from what has been stated above, and I fully coincide in the remark of a learned and impartial critic, the late Dr. Aikin, who, after giving full credit to Galen for talent and acquirements, thus concludes:—"His own mass and modern improvements have now in great measure consigned his writings to neglect, but his fame can only perish with the science itself." The remark which was formerly made with respect to Hippocrates applies equally to Galen, that the great superiority which he acquired over his contemporaries appeared to repress all attempts at further improvement.*

CHAPTER VI.

An account of the successors of Galen—Decline of medical science—Sextus Empiricus—Oribasius—Aëtius—Alexander Trallianus—Paulus Eginetus—Account of the state of Medicine among the Arabians—Conquests of the Arabians—Their patronage of science—Invention of Chymistry—Ah-run—Serapion—Alkhendi—Rhazes—Ali-Abbas—Avicenna—Mesue—Albucasis—Avenzoar—Averroes—Estimate of the merits of the Arabic school.

In investigating the state of medicine during the middle ages, it is apparent that mankind seemed to be satisfied with the progress which had been made in the science, or were conscious of their inability to surpass the limits which had been assigned to it; and the result was, that for some time after the death of Galen we have few illustrious names to celebrate, and no discoveries to record. Literature in general was now, indeed, rapidly declining, and various causes, both moral and political, were coming into operation, which suspended the progress of science and learning for many centuries, and produced what are justly and emphatically denominated the dark ages. Into these causes it is not our business to inquire; it may be sufficient to remark that they were of so universal a nature as to operate on the human mind generally, and therefore to affect every intellectual pursuit. Medicine, among others, felt their paralyzing influence, although, from certain incidental circumstances to be hereafter noticed, it was not allowed to remain so completely stationary as most of the other branches of science.

About the period when Galen flourished, the Roman empire began to exhibit very decided symptoms of that decline, which, proceeding with more or less rapidity, was never altogether suspended, until it terminated in complete destruction. Even in the most splendid state of Rome, the cultivation of science was very limited, and we have had occasion to remark that almost all the physicians who acquired any considerable degree of celebrity were natives of Greece or Asia, and wrote in the Greek language. This was the case with Galen himself and with the few individuals who succeeded him, whose names are of sufficient importance to be introduced into this sketch. The medical writers of the third and fourth centuries have been characterized by Sprengel as "frigid compilers, or blind empirics, or feeble imitators of the physician of Pergamus."†

The only exception to this remark is Sextus Empiricus, who appears to have been a contemporary of Galen, and probably derived his appellation from the sect

* Conring, Introd. cap. 3. §. 16; cap. 4. §. 17, et alibi. *Le Clerc*, par. iii. liv. iii. ch. 1-9, contains a very ample account of all that regards the writings and opinions of Galen. At this period we lose the further aid of this candid and judicious historian of medicine. *Barchusen*, diss. no. 16. *Nouv. Dict. Hist. "Galien."* *Haller*, Bib. Med. lib. i. §. 80, l. *Lauth*, liv. v. par. 1. *Sprengel*, sect. 5. ch. 6. *Ackermann*, cap. 21, 2. *Blumenbach*, Introd. sect. 75. *Goulin*, Encyc. Méth. Médecine, "Galien." *Renauldin*, Biog. † T. ii. p. 170.

to which he attached himself, as there are some treatises of his still extant, in which he attacks the principles of the Dogmatists with considerable acuteness. We may conclude from his works that he was a man of learning and talents, well versed in the principles of the philosophers, and familiar with all the branches of literature and science which were cultivated in his time.* He is, however, the last medical writer to whom the character of Sprengel does not strictly apply. Oribasius, who lived in the fourth century, Aëtius in the fifth, Alexander Trallianus in the sixth, and his contemporary Paulus of Ægina, were all zealous Galenists, who professed to do little more than to illustrate or comment on the works of their great master. Their writings are principally compilations from their predecessors; they are, however, occasionally curious from the incidental facts which they contain, and by furnishing us with extracts or abstracts of treatises which are no longer extant; but this constitutes almost their sole value. The only additions to the practice of medicine which they afford are an account of certain surgical operations, which is given us by Aëtius, and a treatise by Paulus on midwifery, which is more complete than any that had previously appeared, and was long held in high estimation. But even these, which form but a small portion of the whole of their works, are connected with so much credulity and superstition, as to indicate at least the most degraded state of the science, if not the defective judgment of the writer. Aëtius expressly recommended the use of magical arts and incantations, and that, not, as has sometimes been done in a more enlightened age, from a knowledge of the effect they might produce on the imagination of the patient, but apparently from his own opinion of their physical operation on the system.† It must, however, be admitted that both in Alexander Trallianus and in Paulus we meet with various descriptions of disease, which indicate that they possessed the talent of accurate observation; and we may conclude that, although in what respects opinions they were the devoted followers of Galen, yet in the simple detail of facts their authority may be relied upon with considerable confidence.‡

With the death of Paulus, which took place about the middle of the seventh century, we may date the termination of the Greek school of medicine, for after his time we have no work written in this language which is possessed of any degree of merit. Those which occasionally appeared were mere servile transcripts of Galen and his disciples, or compilations formed without judgment or discernment, devoid of original observation, or even of any attempt at generalization or arrangement. In this degraded state was the science of medicine reduced in the former seats of learning, when a new school arose in a different quarter of the world, which will require our attention, from the actual additions which it made to our knowledge, as well as from the mode of its origin and the nature of its connection with the Grecian and Roman schools.

The city of Alexandria still retained its reputation as the great school of medicine, partly resting its fame on the excellence of its former professors, and in some measure depending on the value of its extensive library and other institutions favourable to the cultivation of science, the forms of which at least were still preserved. But even these feeble remains were destroyed by the conquest of the Arabians in the seventh century, who, in the genuine spirit of blind bigotry, appeared to be actuated by the barbarous desire of totally eradicating science from the face of the earth. The catastrophe which befell the Alexandrian library is too well known to be repeated in this place,§ a calamity, the full extent of which can scarcely be appreciated by one who is in the habit of regarding literature only as it exists in modern times, when books of all descriptions are multiplied to an excessive degree, and when the loss occasioned by the most splendid collection would be nearly confined to a single nation or community. It appears, however, that notwithstanding the brutal violence of the Saracen invaders, some books escaped from the general wreck of literature and science, and that there were not wanting some individuals who were capable of estimating their value. Among these relics were the writings of Galen, and we are informed that at an early

§ I have adopted the generally received account of this transaction: but the learned reader need not be informed, that a considerable, and perhaps not an unreasonable degree of doubt attaches to it. *Gibbon*, c. 51. v. 9. p. 392-5.

period of the Saracenic empire they began to be held in very high estimation; they were translated into the Arabic language, were commented upon and elucidated in various ways, and soon acquired a degree of celebrity scarcely short of what they had previously enjoyed among the Greeks themselves. The Arabians were also in possession of the works of Hippocrates, but the simplicity of this author was less adapted to their taste than were the metaphysical refinements and elaborate arrangements of Galen, so that, while the latter was regarded with a respect amounting almost to veneration, the former was little read or estimated.

After the immediate successors of Mahomet had completed their conquest of a considerable part of the civilized world, they rested from their warlike triumphs, and seemed disposed to add to the splendour of their empire by the cultivation of the arts of peace. The patronage of literature was an express object of many of their rulers, and even the works of the Greek philosophers were translated and studied with much assiduity.* But the spirit of Mohammedanism was decidedly averse to intellectual improvement, and we accordingly find that no additions were made to general science, and that very little was accomplished even in the collection of facts and observations. To this remark, however, medicine forms an exception; for although the Arabian physicians adopted implicitly all the theories and speculations of Galen, and seldom ventured in the smallest degree to deviate from his practice, we are indebted to them for the description of some diseases which either made their first appearance about this time, or had not been before specifically noticed.†

I must mention in this place a remarkable occurrence in the history of science, and one which indirectly produced a very important effect upon the subject of this dissertation,—the invention of chymistry. The origin of chymistry, like that of all other sciences, is obscure and uncertain. Traces of what may be called chymical operations are to be found even among the Jews and Egyptians, but it is generally admitted that they are to be regarded as incidental occurrences, depending upon accidental observations, pursued no further than the object immediately in view, and not considered, even by those who practised them, as more than mere insulated facts, leading to no general principles nor to any further investigations. The practice of chymistry as a distinct pursuit seems to have originated with the Arabians, and by them was made subservient to the purposes of medicine.‡ It is not my business to inquire into the mode in which this art took its first rise, or to trace its subsequent progress, except so far as may be connected with my present subject; and this will be the most conveniently accomplished by giving in succession a brief account of the most distinguished writers who belonged to the Arabian school of medicine.

The earliest Arabian writer on medicine, of whom we have any certain account, would appear to be Ahrun, who was a priest at Alexandria. He published a treatise entitled “*Pandects*,” it has not come down to us, but it deserves to be noticed, as it is said to have contained the first description of the small-pox. He was contemporary with Paulus, and from the account of his works which has been transmitted to us by Rhazes, we may conclude that the science of medicine was cultivated at that time with at least as much success among the Arabians as among the Greeks. During the next three centuries, although we meet with the names of many individuals who acquired a certain degree of temporary celebrity, we have none who rendered themselves so far pre-eminent as to entitle them to particular notice in this brief sketch. The first author of whom it will be necessary to give any distinct account is Serapion: he lived in the ninth century, and is said to have been a native of Damascus. His treatise, entitled, according to the fancy of the translators, “*Aggregator*,” “*Breviarium*,” or “*Therapeutica Methodus*,” was written originally in Syriac; its professed object was to give a complete system of the Greek medicine, and to incorporate with it the principles and practice of the Arabians. Like those of the rest of his countrymen, the greatest part of Serapion’s work is taken from those of his predecessors, and particularly from Galen; but it contains some few novelties with respect both to doctrine and to practice, and in one point,

* The Arabians are said to have commenced the study of literature and science in the 108th year of the Hegirah, under the Caliph Almamoun; *Ockley’s Hist. of the Saracens*, pref. p. xi.

† For an account of the Arabian school of medicine generally, the reader is referred to *Freind*, who treats upon every thing connected with it in the most ample manner. See also *Barchusen*, diss. 17. §. 12 et seq. *Sprengel*, sect. 6. ch. 5. *Cabanis*, §. 6.

‡ *Freind*, Hist. Med. pars 2. sub init. *Sprengel*, t. ii. p. 246-266.

the preparation and composition of medicines, as well as in the articles employed, we may notice a decided improvement.*

At the same time with Serapion lived Alkhendi, a multifarious writer, who obtained a very high degree of celebrity among his contemporaries, perhaps more from the variety of his acquirements than from the excellence he attained in any particular department. He is said to have assiduously cultivated mathematics, and the various branches of natural philosophy, as well as medicine; and among other subjects to which he particularly directed his attention, we find astrology expressly enumerated. In relation to his varied attainments, he was styled the subtle philosopher, the learned physician, and the Greek astrologer. As an example, both of the spirit of the age and of the genius of the individual, we may remark that Alkhendi applied the rules of geometrical proportion and of musical harmony to regulate the doses of medicines, and to explain the mode of their operation—a mistaken application of science, which, however gross it may now appear, we must reflect was not entirely exploded until long after the revival of letters.†

We now come to one of the most illustrious of the Arabian school, Rhazes. He was born at Irak in Persia in the ninth century; he is described as a person of various acquirements, as being well versed in general science, and, as his writings demonstrate, of unwearied industry. There is some reason to doubt whether the principal work which has been transmitted to us under his name, entitled “*Continens*,” is precisely in the form in which it was left by its author: but there appears to be sufficient proof of its general authenticity to enable us to deduce from it, as well as from his other acknowledged works, an ample and correct view of the opinions and practice both of Rhazes himself and of his contemporaries. For the most part, the writings of Rhazes are deficient in method and arrangement, and they consist principally of abstracts and comments on Galen and the Greek physicians; but they also contain observations that appear to be original, and we even meet with the description of some diseases which were either new, or, at least, were not noticed by the ancients. Rhazes gives us a correct and elaborate description of the small-pox and measles, detailing the theory which was formed of their nature and origin by the Arabians, and the treatment which they employed. The most curious and original work of Rhazes is his “*Aphorisms*,” in one part of which he professedly gives the result of his own observation and experience. But even this treatise, which was long regarded as of the highest authority in the schools of medicine, contains little that is really new and valuable; and when we compare it with its celebrated prototype, we cannot but be impressed with the very small advance which had been made in the science and practice of medicine during a space of nearly thirteen centuries. The most important additions which Rhazes made were, perhaps, rather in surgery and in pharmacy than in medicine, strictly so called; and it is worthy of notice that, in the latter department, we have some of the earliest indications of the free employment of what were styled chymical remedies.‡

A short time after Rhazes lived Ali-Abbas, a writer of considerable celebrity, who obtained the appellation of the magician. His principal work, entitled “*Opus Regium*,” professes to contain a complete view of the state of medicine in all its branches; it consists chiefly of abstracts of the doctrines and opinions of the Greek physicians, but along with these are contained some original observations. At the time of its publication it was very highly estimated, and perhaps may be considered as possessing more real value than most of the works that proceeded from the Arabian school.§

The fame of Ali-Abbas was, however, almost entirely eclipsed by that of Avicenna,|| who flourished about a century later, and who rose to the highest pitch of celebrity, so as to be regarded by his countrymen as superior to Rhazes, or even

§ *Freind*, p. 481. *Haller*, Bib. Med. lib. ii. §. 137. t. i. p. 380. *Sprengel*, t. ii. p. 301-5.

|| The actual name of this individual is said to have been Al-Hussain-Abou-Ali-Ben-Abdallah-Ebn-Sina. *Sprengel*, t. ii. p. 305. In most cases it appears that the names by which the Arabians are generally known in Europe were not their real names.

to Galen himself. Avicenna was born at Bochara, in the year 980, and was carefully educated in all the learning of the times, consisting principally of the Aristotelian logic and dialectics, with the imperfect mathematical and physical science, that was then taught in the schools of Bagdat. He appears to have been possessed of an ardent desire for acquiring knowledge, and of great industry, but united to a portion of fanaticism, indicative of a defective judgment, and fostered by the spirit of the age, which induced him to conceive himself under the influence of supernatural revelation. After a foundation of general science, he entered upon the study of medicine, which he prosecuted with the same diligence, and with the same spirit of enthusiasm. His reputation became so high, that he was early introduced to the court, and for some years was without a rival in his profession. His death, which took place in the fifty-sixth year, was probably hastened by some political intrigues, in which he unfortunately became entangled.

The works which Avicenna left behind him are numerous, and embrace both general science and medicine. The former long maintained a high character for extent of information and profundity of learning, and, according to the standard of the age, were probably entitled to this commendation. But his fame, both with his contemporaries and with posterity, principally rests upon his great medical work, entitled "*Canon Medicinæ*," which may be regarded as a kind of encyclopedia of all that was then known of medicine, and of the sciences connected with it, anatomy, surgery, therapeutics, and botany. Its celebrity was so great as to have acquired for its author the title of prince of physicians; for some centuries it was the received text-book in most of the medical schools, both of the Arabians and the Europeans; until the revival of letters it superseded, in a great measure, the works even of Galen; it produced scarcely less numerous commentaries and epitomes, and had not entirely lost its authority two centuries ago. Yet the matured judgment of one of the most learned and candid of the modern critics has not hesitated to bestow upon this so-much-vaunted production the character of an ill-digested and servile compilation, containing little that is new, either in the way of observation or of practice. Indeed, the sole aim of Avicenna seems to have been to collect matter from all quarters, without paying any regard to its value, or to the mode in which it was arranged. He was a devoted admirer of Aristotle and Galen, and seemed to imagine that the ultimate object, either of the philosopher or the physician, consisted in being intimately acquainted with their writings, and in defending them against all objections. Upon the whole, after making every allowance for the period in which he lived, it seems difficult to account for the very great credit which he acquired, not only during his lifetime, but which was attached to his writings after his death; a credit so much greater than what they merit, either from the importance of the information which they contain, or the mode in which it is conveyed.*

There are two Arabian writers of the name of Mesue, whose celebrity entitles them to a brief notice in this place, although considerable uncertainty attaches both to their individual history and to their works. The elder of them is said to have lived in the eighth, and the younger in the tenth century; and they are both represented as being Christians of the Nestorian sect, but to have exercised their profession at Bagdat. The elder Mesue is principally remarkable as having been among the first who made correct translations of the Greek physicians, and especially of Hippocrates and Galen, into Arabic; for although he appears to have composed many original works, we do not find that they rose into any high repute even among his contemporaries. To the younger Mesue is usually ascribed a treatise on *materia medica* and pharmacy, which for a long time was in great estimation, and was republished and commented upon even as late as the sixteenth century; it probably contained a full view of the state of the science when he wrote, and is interesting, as it indicates the introduction of several new remedies into medicine; but in other respects it is to be regarded merely as a literary curiosity.†

The last of the Arabians who acquired any considerable distinction as a writer on medical subjects is Albucasis. So little is known of his personal history, that

* Freind, lib. ii. p. 491-2. Haller, Bib. Med. lib. ii. §. 139. Eloy, in loco. Lavrui, p. 282-5. Enfield, v. ii. p. 222, 3. Sprengel, t. ii. p. 305-22. Hutton's Math. Dict., in loco. Goulin, Enc. Méth. Médecine, "Avicenne." "Avicenne," in Biog. Univ.

† Freind, p. 481, 2. Haller, Bibl. Med. Prac. lib. ii. §. 126. Eloy, in loco. Enfield, v. ii. p. 231. Sprengel, t. ii. p. 235.

both his birth and the country in which he lived have been the subject of controversy, and appear to be entirely conjectural. His principal works are on surgery; and the reputation which he acquired in this department is almost as great as that of Avicenna in medicine. He seems to have been a man of learning and talents, to have made himself master of the writings and practices of his predecessors, and to have improved upon them. The description which he has left of his operations shows him to have possessed a degree of boldness and dexterity which could only exist in one who was well acquainted with his art, and had been habituated to the practice of it. His practice was what we should now consider as unnecessarily severe, making much more use of the knife and of the actual cautery than is done in modern times, and in all respects inflicting both more pain and more permanent injury on his patients. The works of Albucasis appear, however, to have afforded by far the most complete view of the practice of surgery which then existed; and from this circumstance, as well as from their real merit, they were for many ages considered as standard performances, and employed as the text-book in various schools and colleges.*

It remains for us to give an account of two individuals, who, although natives of Spain, and residing principally in that country, were of Saracenic origin, and wrote in the Arabic language—Avenzoar and Averroes. Avenzoar was born at Seville, in the end of the eleventh century, and is said to have lived to the unusual length of one hundred and thirty-five years; but probably some error may have crept into this statement, in consequence of both his father and his son having been, like himself, engaged in the practice of medicine. His principal work, entitled "Thaissy,"† which consists of a general compendium of medical practice, displays more originality and discrimination than the writings of any of the native Arabians; so that, although he was professedly a disciple of Galen, he does not hesitate, on certain occasions, to shake off his authority when his opinions or practice were not sanctioned by his own experience. We may collect, from certain parts of his works, that he practised both surgery and pharmacy, as well as medicine, properly so called; and we have many valuable observations on each of these departments. Upon the whole, we may consider Avenzoar as respectable both from his general character and his professional skill, and entitled to our regard as one of the improvers of his art.‡

Besides the reputation which Avenzoar derived from his own merits, he was perhaps still more known among his countrymen as being the preceptor of the celebrated Averroes. Averroes was a native of Corduba, and flourished in the twelfth century; he was of illustrious birth, and highly educated in all the branches both of literature and of science which were then taught in the Saracenic colleges of Spain. From certain political causes he was, in the early part of his life, the subject of religious persecution; but he succeeded in repelling the attacks that were made upon his faith, and was finally reinstated in all his former honours and in the public estimation. These circumstances, coinciding probably with the peculiar temperament of his mind, gave to his character a degree of ascetic gloom and austerity; but he appears to have been a man of distinguished worth and of superior abilities. Averroes's professional occupations were principally in a civil capacity; he is therefore to be regarded, not as a practitioner, but as a scholar, who pursued the study of medicine as a branch of physical science. But such was his ardour in the pursuit of general knowledge, and the fondness which he manifested for this particular department, that he made himself intimately acquainted with it in all its details; and in his great work entitled "The Universal," he shows that he was not deficient in any part of the science which could be acquired by the mere study of books. As a philosopher, he was a zealous and obsequious follower of the opinions of Aristotle, and as a physician, of those of Galen; he published many comments on both of them, which acquired the highest degree of reputation, and for many ages were considered as standard performances. Yet there is reason to suppose that he was ignorant of the Greek language, and, like his contemporaries, became acquainted with Aristotle and Galen only through the medium of Arabic translations. The great estimation in which the works of Averroes were held is

* Freind, p. 506-524. Haller, lib. ii. §. 148. Eloy, in loco. Luth, p. 285, 6. Sprengel, t. ii. p. 327-32.

† Freind designates the Thaissy as "liber qui omnia victus et medicinæ præcepta in plerisque morbis continet:" p. 493.

‡ Freind, p. 492-503. Haller, lib. ii. §. 141. Eloy, in loco. Sprengel, t. ii. p. 332-7.

proved by the number of editions of them which were published from time to time, one of which appeared at Venice so late as the commencement of the seventeenth century. With respect to his medical writings, as they do not profess to be the result of original observation, we cannot be surprised that their reputation is no longer supported. They are, indeed, entirely neglected; and it may be affirmed that, notwithstanding the celebrity which they once enjoyed, and which they so long maintained, they have not left a single permanent addition to the science.*

With Averroes terminated the Arabic or Saracenic school of medicine; after his time we have no writer whose name is sufficiently distinguished to deserve particular mention: even the study of the ancients began to be neglected, while no original observations were made, and no novel opinions or speculations were framed which might tend to exercise the mind or dissipate the darkness which now covered all parts of the world.

If we inquire into the causes of the great celebrity of the Arabian school of medicine, we shall be led to the conclusion that they were rather incidental and factitious, than derived from its absolute merits. It has been justly observed, that a considerable portion of this celebrity must be ascribed to the comparative condition of the neighbouring countries. From the eighth to the twelfth century was, perhaps, the period in which Europe was in the state of the most complete barbarism and superstition. The only remains of a taste for literature and science, or for the fine arts, were found among the Moors and Arabs; and it was from this source, by the intervention of the crusaders, and the intercourse which was thus effected between the Asiatics and the Europeans, that the philosophical and medical writings of the Greeks were first made known to the inhabitants of Italy and of France. And even after their introduction into Europe, it appears that they were for some time read only in Arabic translations, or in Latin versions made from these translations; so that it was not until a considerably later period that they were perused in their native language. Indeed, so completely was the study of the Greek tongue suspended during the dark ages, that it may be doubted whether the writings of the ancient physicians might not have been entirely lost to posterity, had they not been preserved in these translations.

There are, however, two points in which the Arabians conferred a real obligation upon their successors,—the introduction of various new articles into the *materia medica*, and the original description of certain diseases. The additions which the Arabians made to pharmacy consisted partly in the vegetable products of the eastern or southern countries of Asia, which were only imperfectly known to the Greeks, and with which they had no intercourse. Among other substances we may enumerate rhubarb, tamarinds, cassia, manna, senna, camphor, various gums and resins, and a number of aromatics, which were brought from Persia, India, or the Oriental Isles. But a still more important addition which they made to the *pharmacopœia* consisted in what were styled chymical remedies, such as were produced by some chymical process, in opposition to those substances that were used nearly in their natural state. With respect to the origin of pharmaceutical chymistry, it may be sufficient to observe, that a rude species of chymical manipulation appears to have been practised in Arabia in the fifth century, that distillation was performed, and that the metals were subjected to various processes, by which some of their oxides and salts were produced. The immediate object of these processes was the transmutation of the metals; an operation which, for many centuries, formed a main subject of attention to almost all the individuals who were considered as cultivators of natural philosophy.

With respect to the second subject alluded to above, the description of new diseases, it is well known that, from causes which are now altogether inexplicable, diseases of the most marked and distinct nature, which are the least liable to be mistaken or confounded with other affections, and which, had they existed, are too violent to have been overlooked, are not mentioned by the Greek and Roman physicians, and are described for the first time by the Arabians. Of these the two most remarkable are the small-pox and the measles. There is some reason to suppose that the small-pox had been known in China, and the more remote parts of India, at a much earlier period; but it is generally admitted that it was first recognised in the western part of Asia, at the siege of Mecca, about the middle of

* *Freind*, p. 503-6. *Bayle's Dict.*, in loco. *Moreri's Dict.*, in loco. *Haller*, lib. ii. § 142. *Eloy*, in loco. *Nouveau Dict. Hist.*, in loco. *Enfield*, t. ii. p. 226-231. *Sprengel*, t. ii. p. 337-41.

the sixth century, when it raged with great violence in the army of the besiegers. We have remarked above, that the disease was alluded to by Ahrun shortly after its appearance, but it was Rhazes to whom we are indebted for the first clear and distinct account of its symptoms and treatment. There is no subject in the whole range of medical science of more difficult solution than that which respects the origin of diseases, especially such as, when produced, are propagated solely by contagion. The full discussion of this subject would, however, carry me far beyond the limits of this treatise; it is only alluded to in this place as an historical fact, in connection with the writings of the Arabians.*

We are indebted to them for the transmission of the works of the ancient Greek physicians, to which they made certain additions of insulated facts with respect to the description of diseases; but, with respect to the general principles of therapeutics, the additions, if any, are few and imperfect. In anatomy they made no advances, and we have reason to suppose that the examination of bodies, either in a sound or a morbid state, was scarcely practised by them. Medical theory was much attended to, but their theories consisted more in subtle refinements, formed upon the Aristotelian model, than in the study of pathology, or an accurate discrimination of the phenomena of disease. Some little advance appears to have been made in surgery by Albucasis, but he is the only individual who seems to have aimed at improving this branch of the profession; and it may be doubted whether the practice of surgery was not, upon the whole, in a retrograde state during the period of which we are now treating. It is in the department of pharmacy alone that they made any additions of real value; and although in this case it may be attributed more to accidental circumstances than to any enlightened spirit of improvement, yet it is incumbent upon us to acknowledge the obligation, which was both extensive and permanent.†

CHAPTER VII.

State of Medicine in Europe after the Extinction of the Arabian School—Medical Schools of Monte-Cassino and Salerno—*Medicina Salernitana*—Constantinus Africanus—Actuarius—Rise of the Study of Anatomy—Mondini—Gilbert—Effect of the Crusades, of the Reformation, and of the Invention of Printing, on the Literature of Europe—On Medical Science—Alchymists—Establishment of Universities—Linacre—Chymical Physicians—Paracelsus—Appearance of New Diseases.

DURING the flourishing period of the Saracenic school of medicine, which may be considered as extending from the eighth to the twelfth century, the science remained nearly stationary, or was even retrograde among the successors of the Greeks and Romans. We have scarcely a single name of sufficient importance to arrest our attention, and we have no improvements to record, either in theory or in practice. The only attempts that were made in Greece or in Italy during this period, which deserve to be noticed, are connected with the Neapolitan schools of Monte-Cassino and of Salerno, which acquired some degree of reputation in the eleventh century. It was at this period that the physicians attached to the school of Salerno wrote the verses on dietetic medicine, entitled "*Medicina Salernitana*," a work which, as afterward published with the commentary of Arnoldus de Villa-

* On the origin of the small-pox, see *Freind*, p. 524-9; *Mead's* Discourse on Small-pox and Measles, ch. i.; *Thompson's* Inquiry into the Origin of Small-pox; *Plouquet*, *Literatura Digesta*, "Variola, Antiquitas, Historia," in loco: ample references may be found in this learned and laborious compilation on all analogous topics, but we may regret that the writer appears to have aimed rather at multiplying his authorities than estimating their value.

† We are indebted to *Freind* for a candid and judicious account of the Arabian medical school, p. 529-33. *Haller's* second book of his *Bibl. Med. Prac.* is devoted to the same subject. See also *Robertson's* *Charles V.* vol. i. note 28. *Berington's* *Middle Ages*, App. No. 2. *Gibbon's* *History*, vol. x. ch. lii. *Ackermann*, cap. xxvii-xxix. *Oelsner*, *Des Effets de la Religion de Mahommed*, p. 196-9: this author is perhaps too much disposed to exalt the merits of the Arabian school. *Kühn*, *Bib. Med.* sec. 3, of what he styles "Fontes Medicinæ," is entitled "Scriptores Medici inter Arabes præcipui," p. 180-6. *Portal*, *Hist. Anat.* ch. ix. "Des Anatomistes et des Chirurgiens Arabes," t. i. p. 143 et seq. *Blumenbach*, *Introd. sect. 6.* "Arabes."

nova, acquired considerable celebrity, and may be regarded as a valuable document, by its affording, in a small compass, a correct idea of the state of Italian medicine at that early period.*

In connection with this subject we may notice Constantinus Africanus, who is supposed to have flourished about the end of the eleventh century. He was, as his name imports, an African; he possessed an ardent desire to obtain knowledge, studied in the schools of Bagdat, and is said to have travelled even into India. At his return to his native country he was regarded as a sorcerer, and was compelled, in order to save his life, to take refuge in Italy, where he was finally attached to the university of Monte-Cassino. He principally employed himself in translating the works of the Greek and Latin physicians into Arabic, which was at that time the general language of science. His translations are, however, said to be incorrect, and his style barbarous; while his works, which are not professed translations, appear to be composed of transcripts from other authors, without any particular merit, either of selection or of arrangement.†

We must mention in this place a writer whose real name has not been transmitted to us, commonly called Actuarius, from the office which he bore in the court of Constantinople.‡ He is supposed to have lived in the twelfth century. The works which he left are numerous, and, although consisting principally of extracts from Galen and the Arabian physicians, with whose writings he appears to have been familiar, are not without some additions derived from his own observations and experience. He is considered as having been the first Greek physician by whom chymical medicines are mentioned, as well as various articles of the *materia medica*, which were originally introduced by the Arabians. We may regard Actuarius as a diligent collector of facts, acquainted with all the information of his age, and as more free from prejudice and bigotry than the generality of his contemporaries.§

After the extinction of the Saracenic school of Spain, we have an interval of about three hundred years, from the twelfth to the fifteenth century, during which what are termed the dark ages still remain enveloped in the deepest gloom; every department of science was neglected, and among others that of medicine fell into its lowest state of degradation. What remained, either of literature or of science, was in possession of the monks, who were themselves grossly ignorant, and whose interest it was to preserve mankind in the same state of ignorance. The exercise of the medical profession was principally in their hands, and they still adhered, for the most part, to the doctrines and practice of Galen, but with these they mixed up a large portion of superstition, and had not unfrequently recourse to magic and astrology. By these means they obtained an unbounded influence over the minds of the people, and operated so powerfully on the imagination of their patients as, in many cases, to give an apparent sanction to their confident assumption of supernatural agency.|| The only branch of science which was cultivated with any ardour or success was chymistry. The chymistry of these times can indeed only be interesting to us, as having led indirectly to the discovery of various substances, which have been found of great importance in medicine, to which we have already referred. Its immediate objects were twofold, the transmutation of the baser metals into gold, and the discovery of what was termed a universal medicine, which should possess the property of removing all diseases, and preserve the constitution in a state of health and vigour; objects which, it is unnecessary to observe, were completely vain and illusory. Yet by promoting a spirit of research, and by making the experimentalist acquainted with the various forms and properties of the substances on which he operated, they gave him some insight into the physical laws of matter, and by a gradual, although very slow process, laid the foundation of the splendid improvements of modern science. Many of the alchemists of the dark ages, we can have no doubt, were impostors of the lowest description, who were completely aware of the folly of their pretensions; but at the same time there were others who appear to have been the dupes of their own credulity, and who bestowed a large portion of their time and fortune upon these researches. Between

* Haller ascribes the Latin verses of the *Medicina Salernitana* to John of Milan; he remarks, that of this work there had been published "editiones ferè innumerabiles;" Bib. Med. lib. iii. sec. 140. See also Eloy, t. ii. p. 599. Ackermann, sec. 422. and Blumenbach, sec. 114.

|| Sprengel, sec. vii. ch. i.

these two extremes there were some rare cases of individuals, who may be entitled to hold an intermediate rank, who were sincere and honourable in their views, and, without giving full credit to the professions of the alchymists, conceived that the objects at which they aimed were at least not altogether impossible. To these we may add another class of individuals, consisting of that singular and unaccountable compound of knavery and folly, which is not confined to the subject now under consideration, where it is extremely difficult to draw the line between these two qualities, or to decide which of them forms the predominant characteristic.

The school of Salerno, to which we have referred above, obtained a degree of celebrity from its local situation, this city being one of the great outlets from which the crusaders passed over from Europe to Asia in their expeditions to Palestine; and it was probably from this circumstance that Robert of Normandy stopped at Salerno, in order to be cured of a wound which he had received in the holy wars. It was on this occasion that the verses mentioned above, and which were addressed to him, were written. Upon the decline of the Saracenic universities of Spain, the only medical knowledge which remained was in Italy, where a few individuals, who were not of the ecclesiastical profession, continued to comment on Galen and Avicenna, and occasionally to deliver lectures; but we have a long dreary interval, in which there is nothing to arrest our attention, or to relieve the dull monotony of ignorance and superstition.

During this period the school of Salerno still retained its reputation, and was even favoured with especial privileges by the emperors; but its merits were probably rather comparative than absolute, for we do not find any improvements that emanated from it, nor any authors whose writings maintained their celebrity after the age in which they were produced. It is, however, in one respect deserving of our notice, as it appears to have been the earliest establishment in which what may be styled regular medical diplomas were granted to candidates, after they had passed through a prescribed course of study, and been subjected to certain examinations. The regulations are upon the whole judicious, and display a more enlightened and liberal spirit than might have been expected in that age, when the human mind was in so degraded a state.* The school of Salerno maintained its celebrity until the thirteenth century, when it was eclipsed by the general diffusion of medical science through Europe, and more particularly by the rising reputation of the universities of Bologna and Paris.

It was about this period that we may date the commencement of a practice which has eventually proved of the greatest importance to medical science in all its departments—the study of human anatomy. We have already had occasion to remark that the ancients, even in their most enlightened ages, seldom if ever ventured to examine the human subject, but were content to derive their knowledge of it from the dissection of animals which were supposed the most nearly to resemble it, making up the deficiencies by the casual examinations which were afforded them by accidents or diseases, and perhaps more frequently by supposed analogies, or rather by the efforts of the imagination. The individual to whom the credit is ascribed of having so far overcome vulgar prejudice as to have introduced this most important improvement into his art, is Mondini, a professor in the university of Bologna, who is said to have publicly dissected two female subjects about the year 1315, and who published an anatomical description of the human body, which appears to have had the rare merit of being drawn immediately from nature. This work deservedly obtained a high reputation: for three hundred years it was considered as a standard performance, and was used as a text-book in the most celebrated of the Italian universities. Mondini is also entitled to the gratitude of posterity for having given a very early, if not the first example of anatomical plates; the figures were cut in wood, and although, as might be supposed, they were not executed with much elegance or delicacy, they are said to have been correct and expressive.†

About the same time with Mondini lived Gilbert, surnamed Anglicanus, a writer who must be considered as peculiarly interesting to us, from his being the earliest English physician whose name is sufficiently celebrated to entitle him to a place in the history of medicine. There has been much controversy respecting the

* Freind, p. 535-7. Eloy, art. "Salerno." Lauth, p. 291, 2. Ackermann, cap. xxxi.

† Freind, p. 516. Haller, *Bibl. Anat.* §. 120, t. i. p. 146, 7. Eloy, in loco. Portal, *Hist. Anat.* t. i. 209-16. Sprengel, t. ii. p. 432-4. Douglas, *Bibliogr. Anat.* p. 36-9. Blumenbach, §. 118.

date of his birth; but it appears the most probable that he flourished in the beginning of the fourteenth century. At this time medical science, as well as all other kinds of knowledge in this country, was in a state of the lowest degradation. There were no public means of instruction in any of the branches of natural philosophy. The light of science, which had dawned in the south of Europe, had not yet extended to the remote shores of Britain, and the learning of the age, which was confined to the monks, consisted entirely of scholastic disquisitions and the disputations of polemical theology. We are not, therefore, to expect in the writings of Gilbert much of genuine philosophy or of real science; his principal work, which is entitled "*Medicinæ Compendium*," consists chiefly of subtle distinctions, disquisitions respecting trifling and insignificant topics, with minute divisions of his subject, which lead to no useful purpose or general conclusion. His medical theories are principally taken from Galen, while his mode of reasoning proceeds upon the technical principles of the Aristotelian dialectics; he adopts the former without discrimination, and employs the latter without judgment. He frequently refers to the Arabian physicians, and there is some reason to suppose that it was through their means, i. e. through the medium of the Latin translations of their writings, that he made himself acquainted with the opinions of Galen.*

But although we are compelled to pass this general censure upon the works of Gilbert, justice demands it of us to admit, that his defects may be fairly ascribed to the age and country in which he lived, and that he deserves great commendation for the attempt which he made, however imperfect it may have been. Nor are his works entirely without merit or originality; he has described some diseases in such a manner as to show that, under more favourable circumstances, he might have excelled in the art of making observations; he occasionally gives us some particulars of his practice, which prove that he was capable of exercising a correct judgment in the treatment of the cases which were submitted to him, and we are indebted to him for some additions to the *materia medica*, and for some improvements in pharmacy.†

About this period a grand political revolution was commencing in Europe, which eventually produced an entire change in the civil condition of its inhabitants, and indirectly affected, in an equal degree, its science and its literature. The feudal system, after being firmly established for some centuries, began to be shaken, perhaps in the first instance, by the crusades. These expeditions, although undertaken from a spirit of gross superstition and bigotry, yet, by giving a degree of excitement to the mind, and still more by making the crusaders in some degree acquainted with the literature of the Arabians, laid the foundation for subsequent improvements. There has been much controversy, not only respecting the absolute merit of the Arabian literature, but respecting the influence which it had on that of Europe. On the first of these points, as far at least as regards the medical sciences, I have already offered a few remarks; and on the latter I may observe, that at the period of the crusades, whatever may be our estimate of the absolute merit of the Saracenic schools of learning, they were undoubtedly superior to those of the Christians, if indeed these latter can be entitled to the appellation. The armies of the crusaders were certainly not the best adapted either for appreciating the learning of the countries which they invaded, or for transferring any portion of it to their own; but still an intercourse of two or three centuries could not fail of having produced some effect, and in fact we know, not only that Arabian books were read and studied in Italy and France, but that it was almost exclusively by the medium of these books that the knowledge of the Greek and Roman authors was kept alive.‡

The advantages which were derived to the Europeans from their intercourse with Asia were, however, of but little moment compared to the great events to which I alluded above. The first of these was the capture of Constantinople, in the middle of the fifteenth century, by Mahomet the Second. The Greek monasteries of this city had been for some time the refuge of the learned men who had been driven from Italy by the perpetual wars in which that country had been so long engaged.

† Freind, p. 547-50. Eloy, in loco. Aikin's Biog. Mem. of Med. in Gt. Brit. p. 8, 9. Sprengel, t. ii. p. 4026.

‡ Gibbon, ch. lxi. Sprengel, sect. 7, ch. iii. I must remark that the opinion expressed in the text, respecting the influence of the crusades on the literature and science of Europe, differs in some degree from that of Mr. Mills, as stated in his interesting work on the Crusades, v. ii. p. 354-68.

They had taken with them what they considered as their most precious treasures, the manuscripts of the ancient classical writers, probably regarding them more as objects of curiosity than of real importance. These manuscripts had now been buried for a long time in their libraries, their existence being unknown to the rest of the world, when the monks were expelled from their retreats by the Turkish conquerors, and, flying into Italy, carried back with them their classical manuscripts. A spirit of improvement had already begun to manifest itself in this country, which was considerably incited by their guests, who, in their turn, by their change of situation and by the new society into which they were introduced, became more aware of the value of their literary treasures; while their own acquisitions, limited as they were, gave them a degree of respect with their new associates which tended to inspire them with a desire of further improvement.*

The other event to which I referred, and which occurred about thirty years after the destruction of the Byzantine empire, was one of infinitely more importance, both in its immediate and its ultimate effects. Considered in all its bearings, both moral and political, it may probably be regarded as the most important which has ever occurred in the history of civilized society. My readers will not need to be informed that the great event to which I refer is the Reformation. Into the causes of this event, the motives of Luther and his associates, the difficulties with which they had to struggle, and the means by which they succeeded in overcoming these difficulties, it is not our business to inquire. It only remains for me to notice its effects on science, and more particularly on medical science. I have remarked above that a certain degree of mental exertion had begun to manifest itself in the fourteenth century, that this was in some measure brought into action by the excitement produced in consequence of the crusades, and that the minds of men were thus prepared to receive the great truths which were so powerfully impressed upon them by the reformers. The first effect, however, of the Reformation was rather unfavourable to the progress of science and literature. The attention was entirely absorbed by the violence of theological controversy, and the civil feuds which succeeded put a stop to the peaceful labours of the scholar and the philosopher. But if a temporary pause was thus produced, the subsequent advance was proportionally rapid. No sooner were the minds of men delivered from the thralldom of theological bigotry, than they felt a strong impulse to free themselves from the tyranny of opinions on all other subjects in philosophy; and although it still required the lapse of some centuries to shake off the undue authority of Aristotle and Galen, and to form a fair estimate of their real merits, they were at least regarded as fair topics for discussion, while innovators were every day rising up, who ventured to question their infallibility, without the danger of being stigmatized as schismatics and heretics.†

The happy invention of the art of printing, "an art which derides the havoc of time and barbarism," and which fortunately occurred about the same period, most powerfully tended to co-operate with the labours of the reformers, both in religion and in science, by affording them the means of more readily communicating the result of their inquiries, and of preserving the records of knowledge from the danger which they had lately experienced of being totally lost or destroyed.‡ One of the first uses which was made of this important invention was, not only the multiplication of the works of the ancient classics, which had been brought by the Byzantine monks into Europe, but, by making mankind sensible of their value, other works of a similar kind were eagerly sought after, and thus, in the course of a few years, manuscripts were discovered of almost all the classical writings of which we are now in possession.§ The munificence, and even the voluptuous extravagance of Leo X. and the other Italian potentates, by the direct encouragement which they gave to literature and the fine arts, powerfully coincided with the current of public opinion. For, although by inciting the daring spirit of Luther to take those steps of open hostility against the papal authority, which he probably little contemplated in the first instance, they produced effects very different from those originally intended, yet they must be considered

as among the indirect causes which conspired to produce the great mental revolution of the fifteenth century.

The science of medicine in its various departments was not slow in partaking of the beneficial effects of the change which we have been describing. The writings of the Greek physicians, which had for some centuries been studied through the medium of Arabic translations, or even of Arabic commentaries, were now read in their original language, or in correct Latin versions.* It was found that Avicenna, Averroes, and the great luminaries of the Saracenic schools, had in many cases either misunderstood or perverted the doctrines and tenets of Galen, and his genuine writings now began to be substituted for the imperfect transcripts of them which had so long occupied their place. The works of Hippocrates were also printed in their original form; but it required a considerably longer period of mental education to enable the bulk of medical readers to appreciate his merits, so that, although various editions of his works were printed, and learned treatises written to explain them, Galen still retained the pre-eminence in public estimation.

A practice began to prevail about the fifteenth century, which very materially contributed to advance the science of medicine, and especially the practical part of it—the publication of monographs of particular diseases and of individual cases, with the reports of hospitals or other public institutions. This plan was not, indeed, altogether new, for we meet with narratives of cases even in Hippocrates; but it had been either misunderstood, or had been so much perverted from its original design and legitimate object, as to have been rendered of little value. Many of these early collections, it must be acknowledged, were formed without judgment, and consisted rather of marvellous stories than of histories from which any practical inference could be deduced; but they served the purpose of inducing a habit of observation, and of directing the attention more to facts than to mere hypotheses. In each succeeding age we find this plan to have been more generally adopted, and at the same time to have been much improved in its method; so that we may undoubtedly consider it as one of the means by which medical knowledge has advanced so rapidly in modern times.

Before I close the second period of the history of medicine, it will be necessary to make a few observations on the progress of chymistry, and on the influence which it had on medical science. I have already made some remarks on the rise of this science, and on the progress which it made among the Arabians, and have stated that it originated in the futile and sordid desire of converting the baser metals into gold. In its primary object it of course totally failed; yet in the numerous and laboured efforts which the alchemists made to accomplish their object, it is admitted that they acquired considerable information about the nature and properties of the bodies on which they operated, and thus produced various compounds, principally of a metallic nature, which were eminently useful in the arts of life, and especially in pharmacy. We further owe to the Arabian chymists the discovery of the process of distillation, and the art of preparing extracts; they introduced the use of sugar into pharmacy instead of honey, in the composition of syrups and conserves; they seem to have made some approach to the formation of the mineral acids, and to have procured several of the earthy and neutral salts.

The art of alchymy was early transferred into the different countries of Europe, and was pursued with as much ardour as by the Arabians, and perhaps with even more superstition and credulity. Some of the alchemists acquired, during their lifetime, a high degree of popularity, and, notwithstanding the unphilosophical nature of their occupation, are not altogether unworthy of notice in the history of science. Albertus Magnus, bishop of Ratisbon, Raymond Lully, a Spanish ecclesiastic, and Arnoldus of Villanova, a professor in the university of Barcelona, all flourished in the thirteenth century, and left behind them writings which, although they are encumbered with a mass of folly and mysticism, exhibit in a certain degree the spirit of philosophical research, together with an ample share of industry and patient investigation.† In the same age lived Roger Bacon: he

* There is reason to believe that Greek was little read in any part of Europe until after the capture of Constantinople in 1453; Ockley, *pref.* p. xii.

may be classed among the alchemists, inasmuch as he adopted some of their principles and practices; but in the turn of his mind, and in the spirit with which he entered upon his experimental researches, he exhibited a genius which far outstripped the age in which he lived.* The philosopher's stone, which was the object of so much painful research, besides its property of producing gold, was supposed also to possess the power of curing all diseases, and hence obtained the title of the universal medicine. This vain and fantastical notion was indirectly the cause of some pharmaceutical discoveries; for to this we may consider ourselves indebted for the mercurial preparations, and for the experiments of Basil Valentine on antimony, which led to their introduction into medicine about the end of the fourteenth century.

Among the distinguishing features of the period at which we are now arrived, I must not omit to mention the various universities which were established in many of the great cities in the southern parts of Europe, of which the medical chairs, in most cases, formed a very distinguished part. I have already had occasion to mention the university of Salerno, which was the first of these establishments after the destruction of the Roman empire. The next in order of time appears to have been that of Montpellier, which is said to have been established not long after that of Salerno, and which acquired a high degree of reputation, which it maintained for many centuries. We are informed, that Bologna had acquired considerable celebrity as a school of medicine in the thirteenth century; that about half a century later medical lectures were delivered in the universities of Vienna and Paris; and that about the same time medical schools were established in Padua, Pavia, Milan, Rome, and Naples, and most of the other cities of Italy, which each of them acquired a certain degree of reputation, necessarily varying with the abilities and characters of their professors, but all contributing to advance medical science, both by the actual acquisition of knowledge, and by the influence which they exercised in removing the undue veneration that was still paid to the writers of antiquity.† In the north of Europe the progress of literature and science was much more tardy. The natural sciences were scarcely regarded as an object of attention, and medicine was still strictly confined to the study of the works of Galen, or even to those of his Arabic translators. The only exception of which our country can boast is Linacre, a native of Canterbury, who, after studying at Oxford, travelled into Italy, and spent some time at the court of Florence, where he acquired a portion of that love of literature which so eminently distinguished the family of the Medici. On his return to England he was appointed physician to the royal household, and employed his influence in establishing medical professorships in the universities of Oxford and Cambridge, and in forming the foundation of the London College of Physicians.‡

From the various causes which have been mentioned, and probably from some others of less moment, a spirit of general improvement now began to manifest itself; the arts and sciences gradually revived; philosophy, in all its branches, was studied on a more correct plan and with a more enlightened object, and medicine was not slow in partaking of the beneficial influence. One of the first symptoms of this improvement was an increasing relish for the writings of Hippocrates, and the revival of his method of studying and practising medicine. The taste for complicated theory and refined speculation gradually declined, and in the same proportion the value of correct observation and an accurate detail of facts began to be duly estimated.

A circumstance which tended in a considerable degree to shake the authority of

* Freind, p. 537-543. Campbell, *Biog. Brit.*, in loco. Bale, *Scrip. Illust. Brit.* p. 342 4. Cave, *Hist. Lit. t. ii.* p. 324-6. Bayle, in loco. Eloy, in loco. Berington, book v. p. 373. Galen, and to diminish the veneration in which his opinions had been held for so many ages, was the rise of the sect of the Chymical Physicians. After chymistry had been used with advantage for the purpose of improving the processes of pharmacy, it was applied to the explanation of the phenomena of vitality, and of the operation of morbid causes upon the living system. The theories of these chymical physicians we now regard as altogether false and inapplicable; but they were advanced with so much confidence that they obtained many adherents, and for some time the opinions of the medical world were divided between the rival doctrines of the Galenists and the Chymists.

Among the most noted supporters of the chymical theory was Paracelsus, an individual whose claim to our notice depends more upon his consummate vanity and presumption than upon his abilities and acquirements. His professed object was to undermine the authority of the Galenists; and for this purpose he did not hesitate to hold forth the most absurd claims, and to practise the basest arts of quackery. He boasted that he had discovered the elixir vite, the universal remedy, of which mankind had been so long in search; and he publicly burned the writings of Galen and Avicenna, because, in consequence of his discovery, they were of no further use. It is somewhat difficult to determine in what degree Paracelsus was actually the dupe of his own folly; but whatever may have been his real opinion of the efficacy of his elixir, his own death, at the early age of forty-eight, served to humble the confidence of his followers, and to reduce his reputation to its real standard.

But although the personal character of Paracelsus received an irreparable shock by this event, his doctrines continued to attract a number of zealous advocates. With respect to the nature of these doctrines, it will be necessary to say but a few words in this place. The leading principle of the Chymists was, that the living body is subject to the same chymical laws with inanimate matter, and that all the phenomena of vitality may be explained by the operation of these laws. The proofs which they adduced in favour of this principle, and the illustrations which they gave of the nature of these laws, were completely futile and unsatisfactory; and it may be asserted that the strength of their reasoning was much more apparent in the mode by which they attempted to controvert the hypothesis of the Galenists, than in the direct arguments which they brought forward in favour of their own doctrine. In truth, the chymical elements of Paracelsus were at least as hypothetical as the physiological elements of Galen, and were even less applicable to the explanation of the vital actions of organized beings. The only obligation which we owe to the chymical physicians is the introduction into medicine of certain substances, chiefly metallic preparations, which, in the hands of the more enlightened practitioners of modern times, have proved very valuable additions to the *materia medica*.*

After the death of Paracelsus, his peculiar theories fell into disrepute and were little attended to; but the sect of the chymical physicians continued to flourish even as late as the seventeenth century, when we meet with many examples of men of learning and sagacity who attempted to explain the phenomena of the animal economy by the laws of chymistry. To the visionary speculations of the Chymists there was united a large portion of superstition and mysticism; and so much did this feeling coincide with the spirit of the times, that even the men who were most illustrious for their learning and science were either actually infected with these notions, or did not venture so far to oppose the prevailing opinions of their contemporaries as to avow their disbelief of them. Astrology and magic were generally practised by the members of the medical profession, while various rites and ceremonies were observed, which implied the belief of supernatural agency, but which, by a singular inconsistency, was supposed to be a constant and necessary part of the process.

Before we conclude this portion of our subject, we must notice the remarkable circumstance, that about this period, during the fourteenth and fifteenth centuries, some very formidable diseases made their appearance in Europe, the origin of which is still very obscure, after all the discussion and investigation that has

* Le Clerc, p. 792 et seq. Barchusen, Diss. 19. Conring, cap. xi. §. 16, 17. Haller, Bib. Med. t. ii. p. 2 et seq. Eloy, in loco. Sprengel, sect. ix. ch. 2. Cabanis, sect. ix. Hutchinson's Biog. Med. vol. ii. p. 197-209. Enfield, vol. ii. p. 451-4. Aikin's Gen. Biog., in loco. Blumenbach, Introd. §. 169. Renaudin, Biog. Univ., "Paracelse."

taken place respecting them. Among these, one of the most remarkable is what was termed the *Sudor Anglicanus*, which is first mentioned about the end of the fifteenth century, and which, for about fifty years, raged at intervals with extreme violence in England and in some other countries in the west of Europe.* In the fifteenth century we have the first correct description of the hooping-cough; and from the manner in which it is spoken of by the contemporary writers, it would appear that it was considered by them as a new disease. The sea-scurvy, if not entirely unknown to the ancients, was at least not distinctly recognised until this period, so that, if it existed previously, we may conclude that it was less violent in its effects: a circumstance which has been ascribed, with great plausibility, to the spirit of naval enterprise which sprang up at this period, and which led to the undertaking of long voyages.†

The great number of establishments which were formed during the dark ages for the cure of leprosy, was at one time supposed to be a proof that it was a new disease in Europe, imported, as was imagined, from Asia by the crusaders. There has been much nosological discussion concerning the exact nature of the disease to which this term ought to be applied; whether there were actually two species of leprosy, one of which was indigenous in the East, and another species in Europe. Some writers have conceived that a combination of the two was produced at this period, while others, again, have supposed that the disease had previously existed in Europe, but that, in consequence of the greater degree of communication between the different parts of it, which was brought about by the crusades, the disease was either more extensively propagated, or at least was brought more into notice, and that more active means were therefore employed for its relief.‡

It was about the same period, when the western part of the old continent was in its lowest state of degradation, that we hear of the ravages of those varieties of fever emphatically styled the plague, which were described in the thirteenth, fourteenth, and fifteenth centuries as invading various parts of Europe and Asia, and sweeping away a large proportion of the inhabitants.§ The accounts which we have of these epidemics would indicate that they were not an absolutely new disease, but that the symptoms were modified and aggravated by the peculiar condition of the great bulk of the people: a conclusion which is confirmed by the fact, that, as the physical and moral condition of nations has been ameliorated, the occurrence of these diseases has become proportionally rare, so that we conceive them to be almost incompatible with the improvements in civilization and in medical police which exist in the greatest part of Europe.

But whatever may be our opinion concerning the origin of the leprosy and the plague, there is another disease where, from the peculiarity of its symptoms, its decidedly contagious nature, the ordinary method of its propagation, and the universality of its occurrence, we are enabled to fix the date of its appearance in Europe with more certainty. It is now generally agreed that it was near the close of the fifteenth century that the symptoms of syphilis were first recognised in Italy, from which country the disease very rapidly extended over the whole of Europe. Concerning its primary origin much controversy has taken place; many writers have attempted to prove that it was brought into Europe from America by Columbus; but this opinion, which was at one time pretty generally received, is now abandoned, nor are we able to offer any plausible conjecture respecting its introduction from any other quarter.

The same difficulty, indeed, exists in this case as in that of all those diseases which are produced by no cause except by a specific contagion. Almost every individual is obnoxious to them upon the application of this cause, and this liability appears to be little affected by constitution, age, habits of life, climate, and other external circumstances. The question is, how were they first produced? It is impossible to imagine that the first created individual was born with all these diseases upon him, yet we know of no distinct cause now in operation which could, in the first instance, have generated them. These remarks apply to the small-pox and the measles, which, as was stated above, were first known to the Europeans about

* Sennert, De Feb. lib. iv. cap. 15. Freind, p. 567, 8. Plouquet, "Febris Sudatoria," t. ii. p. 162. Cullen's Synopsis, t. ii. p. 77, 8. Sprengel, t. ii. p. 491-4.

§ Plouquet, "Febris Maligna," and "Pestis," in loco. Cullen, t. ii. p. 74-7, 139-41.

the middle of the sixth century, and it applies perhaps still more remarkably to the case of syphilis. This point must be regarded as one of those mysteries of which at present we are unable to offer any solution. It is true that the manners of the age in which this disease is recorded to have first made its appearance were grossly licentious, and in many respects unfavourable to health; but still we see no satisfactory reason why the specific poison of this disease should have been generated; yet it appears impossible to conceive that, if it had previously existed, it could have remained for any length of time unknown or undescribed.*

I have now brought down the sketch of the history of medicine to the period when the light of improvement was bursting forth from various quarters, when men were engaged in the investigation of the different departments of science upon a plan which, although not free from error, was more correct than that of their predecessors, and which, by a slow but steady process, led to the establishment of those principles which eventually produced the complete triumph of truth and philosophy over error and superstition.

CHAPTER VIII.

General View of the State of Medicine during the Sixteenth Century—Revival of the Hippocratean School—Account of the Galenists—the Chymists—The Anatomists—Vesalius, Fallopius, Eustachius.

I HAVE already given an account of the manner in which the taste for the classical writers of antiquity was gradually developed during the fifteenth century, and I stated that in medicine, as well as in the other departments of science, the Greek writers began to be studied in the original, instead of their being read through the medium of translations and commentaries. As this taste was further matured, the works of Hippocrates continued to rise into estimation in preference to those of Galen, and a new school of medicine was formed, which obtained the name of Hippocratean, the professed object of which was to proceed upon the inductive principle, of first ascertaining facts, and by their generalization to form the theory. That in every instance they adhered to this plan we cannot affirm: indeed we have too many instances where they forgot or misapplied their own principles, but still the importance of accurate observation was generally admitted, and although mankind could not at once abandon their former errors, they became aware of their existence, and of the method by which they might be corrected.

The contest between the Galenists and the Chymists, which agitated the whole medical world during the fifteenth century, was indeed still maintained through the sixteenth; but it was conducted upon more rational principles, and by men of more enlarged and more enlightened views. The Galenists were for the most part more scientific and learned than their adversaries; they consisted of the professors in the universities, and what may be styled the regular practitioners: and although they were still strongly attached to the tenets of their master, they did not omit to collect facts and to watch the phenomena of disease. Their practice may be characterized as being at the same time complicated and inert; their materia medica was principally taken from the vegetable kingdom, while their prescriptions were long and multifarious, consisting of a prodigious number of articles, combined together in such a manner as to render it almost impossible to conceive the probable operation of the compound, their indications, at the same time, being derived from an incorrect hypothesis, and being often either unintelligible or impracticable.

The Chymists were the bold empirics of the day, without learning or experience; but they endeavoured to supply the deficiency by confidence and temerity, and by

* Freind, p. 568-583. Astruc, *De Morbis Veneriis*. Hunter, on the Ven. Dis. p. 9, 10. Sprengel, t. ii. p. 499, et seq. Plouquet, "Syphilis, Historia," &c., in loco. Black's Hist. of Medicine, p. 147-155.

these formidable weapons they frequently triumphed over their adversaries. They discarded the long prescriptions of the Galenists, rejected many of the articles of their pharmacopœia, while they introduced the active metallic preparations, and made free use of the most powerful remedies of all kinds. The rival sects mutually upbraided each other with the injurious effect of their respective plans of treatment, and probably there was but too much foundation for their accusations; for if on the one hand the Chymists, by their rashness committed many fatal blunders, the Galenists, by their feeble remedies, must have frequently failed in subduing disease or arresting its progress.

It appears that, upon the whole, the Chymists, like the analogous characters in the present day, acquired a greater share of popularity than their opponents. Their arrogant pretensions, the more decisive and intelligible nature of their indications, coupled with the artifices which they practised for the mere purpose of acquiring popularity, gave them a decided advantage over their more learned and more dignified rivals, who were both unable and unwilling to contend with them in the race of empiricism. By degrees, however, the chymical physicians rendered themselves more worthy of the public estimation, by making themselves better acquainted with the principles and practice of their art; the search after the philosopher's stone was gradually abandoned; and although many of the doctrines which they still professed were altogether unfounded, they were less palpably absurd than those of their predecessors.

Another circumstance occurred about the period of which we are now treating, which contributed to produce a most important reform in the science of medicine—I refer to the study of human anatomy. With a very few exceptions, which have been noticed above, during a space of more than a thousand years, since the death of Galen, very little advance had been made in our acquaintance with the structure of the body. The professors of the Arabian school, with their successors in Italy and France, for the most part contented themselves with copying the descriptions of the ancients, without ever calling in question their accuracy, or endeavouring to confirm or refute them by their own observations. Even after the examination of the human subject had been practised for some time, and its necessity generally acknowledged, it was long before mankind could so far free themselves from the tyranny of authority as to admit that any imperfection could exist in the works of Galen, or that his descriptions were not to be preferred even to the evidence of the senses.

In reviewing the state of medical science during the sixteenth century, it will assist us in our progress if we arrange the principal authors under the three classes of the Physicians strictly so called, the Chymists, and the Anatomists. Under the first head we purpose to include both the writers who still adhered implicitly to the tenets of Galen, and those who, paying less regard to mere authority, devoted themselves more to observing the phenomena of disease, and the effects of remedies, and who may be considered as having laid the foundation of the modern Hippocratean school. Of these, some of the most distinguished by their character or writings were Cornarus and Mercurialis in Italy, Hollerius, Fernel, and Duret in France, Lommius and Forest in Holland, Sennert, Plater, and Foës in Germany, and Linacre in England.*

The limits to which I am necessarily confined will not permit me to enter into any detail of the individual merits of these authors, or into any analysis of their writings or opinions. For the most part, they were possessed of a competent knowledge of ancient literature, and well acquainted with the works of the Greek physicians; many of them were professors in universities or teachers of medicine, and engaged in extensive practice. They were generally diligent collectors of facts, and many of them voluminous writers, either publishing their own observations, or commenting on the ancients. Their practice was, in a great measure, taken from Galen, with the additions that had been derived from the *materia medica* of the Arabians, and in a few instances from the Chymists; but these latter were regarded as dangerous and empirical, and it was not until they had been long sanctioned by popular use that they were received into the authorized pharmacopœias. The actual advance which the practice of medicine received from these authors was not very considerable; but by their learning and diligence, and their general respectability, they contributed to raise the character of the profession,

* Sprengel, t. ii. passim. Cabanis, ch. ii. §. 10.

and to prepare the mind to receive the improvements in science which were gradually unfolded in the next century, and to apply them to the department of medicine.

With respect to the Chymists of this period, although they composed a numerous and active body, yet there is none of them whose name is sufficiently distinguished above his fellows to require being particularized in this place. As science and knowledge gradually advanced, the absurdity of their speculations was more generally perceived, and their pursuits were either abandoned, or were directed by a more philosophical spirit; and although the search after the universal medicine was not entirely discarded, they began to occupy themselves with inquiring into the chymical constitution of the body, and investigating the changes that were induced in it by disease. This investigation was, indeed, attended with little success: their experiments were crude and imperfect, and their modes of analysis altogether inefficient. But still some important observations were made, and new processes were invented, and the foundation began to be laid for the more enlightened views of their successors in the succeeding century.

But the benefit conferred upon the science of medicine by the labours of the Chymists was trifling and uncertain compared to the great and direct advance which was produced by the researches of the Anatomists. Some attention had been paid to the structure of the body by the earlier Italians, and they had even ventured, in a few instances, to dissect the human subject; yet scarcely any discovery or any improvement deserving of notice had been made for many ages, when Vesalius, about the middle of the sixteenth century, entered upon his career of inquiry. He was the first anatomist who threw off the yoke of authority, which had been imposed by a blind veneration for the opinion of the ancients, and who ventured to conceive the possibility of error in the writings of Galen. Vesalius prosecuted his researches with unwearied diligence; and, disregarding the obloquy which was heaped upon him, he succeeded in publishing an anatomical work, which at this day we behold with admiration, and which maintains its character as a faithful transcript of nature.*

But the reputation of Galen was too firmly established to be affected in any considerable degree by the observations of any single individual, however highly he might be entitled to the respect of his contemporaries. Long and acrimonious discussions occurred between the defenders and the opposers of Galen, some maintaining that his descriptions of the parts of the body were absolutely perfect, while others undertook to prove, by direct and palpable facts, that Galen's knowledge of the human form was not complete. It was asserted, on the one hand, that he had seldom examined the human subject, and that his descriptions were frequently taken from apes and monkeys; an imputation which was firmly denied by his zealous advocates. Eustachius, Fallopius, and others of great and deserved reputation for their anatomical skill, undertook the defence of Galen; and it was not until after a long and severe struggle that the truth was established, and that it was agreed that the anatomy of the ancients was in many parts imperfect, and that the errors which had been pointed out by Vesalius actually existed.† It would be foreign to my purpose to enter into a minute examination of the labours of the individual anatomists, or to mention in detail the successive improvements which were effected in their department. With respect to the practice of medicine, which is my more immediate object, it does not appear that they effected any direct improvement; but they contributed indirectly to its advancement, in no small degree, by completely establishing the important point, that the opinions of the ancients were not to be considered as infallible, but were to be subjected to the ordeal of free inquiry.

CHAPTER IX.

State of Medicine during the Seventeenth Century—The Chymical and Mathematical Sects—Progress of Anatomy—Fanatics—Chymical Physicians—Sylvius—Willis—Sydenham—Mathematical Physicians.

ALL the changes of opinion which we have described as occurring in the sixteenth century, continued to advance with an accelerated progress during the seventeenth. The preference which was given to Hippocrates over Galen was daily gaining ground, and, as the consequence of this, the habit of correct observation was confirmed, and the value of the observations was more justly appreciated.

In the mean time anatomy was making rapid strides. Being a science which depended more immediately upon the accumulation of matters of fact, which required for their attainment little more than industry and mere observation, errors were more readily discarded than on those subjects in which much reasoning was necessary, and in which it was rather an inference from facts than the facts themselves which constituted the object of the investigation. The investigations of the anatomists extended to every part and structure of the body; the forms and texture of the bones, the muscles, the nerves, the vessels, and the various viscera were each in their turn made the subject of particular and minute examination by some of the eminent men of the age. These labours were amply rewarded by the splendid discovery of the circulation by the immortal Harvey, and of the absorbent system by Asselli, Rudbeck, and Bartholine; while the structure and office of the lungs, and the relation which it bears to the heart, were explained by Malpighi, Hooke, Mayow, and their associates.*

With respect to the chymists of this period, their opinions were gradually disengaged from the tissue of mystery and credulity in which they had been so long involved, when about the middle of the century the science was finally placed upon its correct philosophical basis by the genius of Boyle. He correctly regarded it as an investigation into the change of properties which bodies experience by their action upon each other, and he pursued the investigation, not by presupposing the existence of certain occult causes and hypothetical agencies, but by an accurate examination of the effects which bodies actually produce upon each other, when placed within the sphere of their mutual action.†

It is, however, not a little remarkable that while the science of chymistry generally, and more especially the sect of the chymical physicians, was purifying itself of its grosser errors, we meet with not unfrequent instances where it continued to be combined with a singular degree of fanaticism. There was indeed no period, since the time of Paracelsus, when there were more remarkable examples of the prevalence of this spirit, and in no country were they more notorious than in England. The writings of Fludd, who practised in London in the early part of the seventeenth century, afford a curious compound of learning and folly, of profound erudition, united to an implicit faith in astrology and in all the cabalistic opinions of the Jewish doctors.‡ Perhaps a still more remarkable example of this combination is that of the celebrated Kenelm Digby, a man of rank and of refined education, who, during his travels on the continent, became initiated into this mysterious chymical philosophy, and on his return gave a specimen of his opinions by publishing an account of the virtues of the sympathetic powder.§

* The fourth volume of Sprengel is principally occupied with a luminous view of the anatomical discoveries of this period.

§ Sprengel, t. v. p. 9; Eloy, in loco; Campbell, *Biog. Brit.* in loco. *Aikin's Gen. Biog.* in loco.

Another of these individuals who obtained great celebrity was Valentine Greatrix, who cured all diseases by the imposition of the hand, and who even ventured to oppose his power in this respect to the royal touch of Charles.* These circumstances are interesting, not merely as forming a part of the history of medicine, but as displaying a singular feature in the history of the human mind; demonstrating the difficulty which exists in eradicating from it errors and follies, even the most gross and palpable, when they have once become deeply rooted.†

While what may be more strictly termed chymistry was advancing into the state of a science, a combination was formed between its principles and those of physiology, which gave rise to the new sect of the chymical physicians. Their leading doctrine was, that the operations of the living body are all guided by chymical actions, of which one of the most important and the most universal is fermentation. The states of health and of disease were supposed to be ultimately referrible to certain fermentations, which took place in the blood or other fluids, while these fluids themselves were the result of specific fermentations, by which they were elaborated from the elements of which the body is composed. Again, certain humours were supposed to be naturally acid, and others naturally alkaline, and according as one or the other of these predominated, so certain specific diseases were the result, which were to be removed by the exhibition of remedies of an opposite nature to that of the disease in question. According to the theory of the chymical physicians, fever was supposed to originate in an acid condition of the humours, and was consequently to be cured by alkalies: and in conformity with what is so often found to take place in tracing the history of medicine, they discovered that alkalies were actually the most efficacious remedies for fever.

The individual who may be considered as having first given a connected and consistent view of the theory of the medical chymists is Sylvius. He was born at Hanau in Flanders in 1614; he graduated in the university of Basil, practised for some time at Amsterdam, and finally was appointed to fill the chair of practical medicine at Leyden, where by his genius and eloquence he acquired a high degree of popularity. From this circumstance his peculiar opinions obtained a very extensive circulation, and the hypothesis of fermentation, with the acid and alkaline states of the fluids, after some time became the fashionable doctrine of the French and the German physicians, and had many zealous defenders in our own country.‡

One of the most respectable of the advocates of the chymical doctrines of medicine was our learned countryman Willis. He was only a few years younger than Sylvius, and was early in life attached to the science of chymistry, which he afterward applied with much ingenuity to the explanation of the functions of the animal economy. In the year 1659 he published his celebrated treatise on fermentation and on fever, the object of which is to prove that every organ of the body has its peculiar and appropriate fermentation, and that a morbid state of these ferments is the cause of all diseases. The hypothesis is in itself totally false, but it is supported by considerable ingenuity, and his works are of real value, as containing an accurate account of the phenomena of disease. Willis was also the author of some treatises of very considerable merit on the nervous system, and on various physiological topics, by which his reputation is amply supported as one of the most eminent medical philosophers of the age.§

The reputation of Willis has, however, been somewhat obscured by the still higher reputation of Sydenham, a man scarcely inferior to any that has passed under our review. He has been frequently styled the English Hippocrates, and there are various points of analogy between them, both as to general character, and as to their peculiar mode of viewing the operations of the animal frame. The writings of Sydenham, like those of his great predecessor, abound in theory, but they also resemble those of Hippocrates, in containing the most accurate detail

§ Barchusen, Diss. 23, §. 15 et seq. Haller, Bib. Med. §. 685. Eloy, in loco. Sprengel, t. v. p. 73-6. Aikin, in loco. Biog. Univ. in loco.

of facts, indicative of a mind of great sagacity, which enabled him to seize upon the most essential features of a disease, and to direct his attention to those points alone which tended to illustrate the nature of the morbid changes that were produced. But the great merit of Sydenham, that which has raised his reputation to so high a pitch of celebrity, and which causes his works to be still read with admiration, is the same with that which was ascribed to Hippocrates, viz. not allowing his speculative opinions respecting the nature or cause of diseases to interfere with the treatment. He carefully observed the operation of remedies on the symptoms, and the action of the various external circumstances to which the patient is exposed, and from their effect he deduced his indications. He accommodated his theory to the facts, not, as is too frequently the case, the facts to the theory. He agreed generally with Willis, in ascribing the origin of disease to certain morbid fermentations, and he conceived the primary changes to take place, not in the solids, but, according to the opinion almost universally adopted at that period, in the fluids; this, indeed, may be regarded as a necessary consequence of the assumed hypothesis.

In one important point he agreed very nearly with Hippocrates, that diseased action consists essentially in an effort of nature to remove some morbid or noxious cause, and that the great object of the practitioner is to assist in bringing about the proper crisis, and to regulate the actions of the system, so as to prevent either their excess or their defect. The practice was necessarily of a kind which, in the present day, would be styled somewhat inert, consisting rather in attempts to palliate certain symptoms, than in any attempt to counteract or remove their cause. But although we may conceive that the object in view was not always precisely what it would have been, had he not been somewhat biased by his hypothesis, the mode in which he proceeded to effect his indications is, in most cases, very judicious. We may, perhaps, venture to affirm that there are few practitioners, even in the present day, who were better acquainted with the *juvantia* and *lædèntia*, who were more successful in attaining a just medium between excessive caution and undue vigour, and whose proceedings were more guided by the dictates of a sound understanding, enlightened by an extensive range of observation, and an ample store of well-digested experience.*

I have spoken of Sydenham in connection with Willis and the chymical physicians, because in many parts of his writings he adopts the hypothesis, that fermentation and other chymical changes in the state of the fluids are the primary causes of disease. Yet I have been at the same time especially careful to point out that the distinguishing merit of Sydenham consisted in his not manifesting an undue attachment to any theory, but in devoting himself to the study of disease, and the effect of remedies upon it. This merit was not unperceived by his contemporaries, and we learn that he was held by them in great respect. Yet the general spirit of the age was so entirely devoted to hypothesis and speculation, that he can scarcely be said to have made any great impression upon the general state of medical opinion, or to have materially diverted the mind from an almost exclusive attention to the theories which were then so prevalent. Indeed, with every feeling of admiration for the character and acquirements of Sydenham, it must be admitted, that he was not himself fully aware of the great principle, which is the foundation of true philosophy, as well in medicine as in every other department of science, that all theory not derived from the generalization of facts is objectionable, and almost necessarily leads to erroneous conclusions. Sydenham's natural sagacity caused him to feel the value of the inductive method, but it was more from this circumstance than from any abstract conception of its importance, that he was induced to adopt it. The state of medical science was indeed scarcely ripe for that reform which had now commenced in many other departments of philosophy. It is more a science of observation than of experiment, and the observations are of peculiarly difficult execution, depending upon the combined operation of various causes, and involving much complication in the effects, the respective proportions of which it is often extremely difficult to ascertain and to appreciate. Hence it required a more matured state of medical knowledge before we could arrive at the great truths which had been promulgated by Bacon, and which were generally recognised in the other departments of science. Although

* Haller, Bib. Med. lib. 10, t. iv. p. 188 et seq. Eloy, in loco. Sprengel, t. v. p. 566-576. Cabanis, §. 12. Aikin, in loco; Renaultin, Biog. Univ. in loco.

mankind were aware of the importance of observation and experience, they were not sensible of their full value; and it required another century and various successive revolutions of theory, before they could be detached from the hypotheses that had been transmitted to them from their predecessors, and had been sanctioned by the authority of so many illustrious names.*

One of these revolutions was produced by the rise of a new theory of medicine, perhaps more captivating than any which had yet appeared, from its scientific aspect and its high pretensions; we allude to the doctrines of the Mathematical Physicians, or, as they have been termed, the *Iatro-mathematical School*. The rapid advance which had taken place in mathematical science during the latter part of the sixteenth century, and the fortunate application of it to various branches of natural philosophy, induced some of the Italians to apply it to the explanation of the phenomena of the living system. Of these, one of the first, both in order of time and of celebrity, was Borelli. He was a profound mathematician, and a man entirely devoted to scientific pursuits; and, in his well-known treatise on muscular motion, he illustrated in a very happy manner the mode in which certain functions of the body may be elucidated and explained on mechanical principles. Some of the data which he assumes are now admitted to be incorrect, and in some cases the deductions are not the fair results of the premises; but upon the whole it is allowed that he established many important points, and considerably advanced our knowledge of the animal economy. The new path of inquiry, which had been thus so successfully opened by Borelli, was soon occupied by many of his contemporaries and pupils, and, according to the usual custom on such occasions, it was carried by them far beyond its legitimate limits, and was applied to various topics with which it had little connection. One of the most active and ardent in this pursuit was Bellini, who was a professor at Pisa, and who exhibited such marks of early genius as to become a lecturer at the age of twenty. His acquirements were varied, and his talents were splendid, but they may be pronounced to be rather specious than solid, and to be more adapted to excite applause than to advance true science. The mode of reasoning which had been employed by Borelli to explain the action of the muscles, which is essentially a mechanical function, and where such reasoning was therefore appropriate, was extended by Bellini to all the functions and actions of the body, both in health and in disease. He maintained, not only that every part of the body is under the influence of gravity and mechanical impulse, but that these are the sole agents, and that we may explain all the vital functions merely by the application of the principles of hydrostatics and hydraulics.

The imposing air of the new hypothesis instantly acquired for it a number of converts, embracing many of the most learned men of the age. The body was regarded simply as a machine composed of a certain system of tubes, and calculations were formed of their diameter, of the friction of the fluids in passing along them, of the size of the particles and the pores, the amount of retardation arising from friction and other mechanical causes, while the doctrines of derivation, revulsion, lentor, obstruction, and resolution, with others of an analogous kind, all founded upon mechanical principles, were the almost universal language of both physicians and physiologists towards the close of the seventeenth century. In proportion as the Mathematical sect gained ground, that of the Chymists declined, while between the two the old Galenists may be considered as nearly extinguished. In Italy and in England the mathematical doctrines had many learned and zealous adherents; it had also some followers in France, although in that country, as well as in Holland and Germany, the chymical theory still continued to prevail.†

When we consider the very great influence which the *iatro-mathematical* sect exercised over the theories of their contemporaries, we may perhaps be surprised that it did not produce any very decided or immediate effect upon their practice. In fact, their reasoning was more applicable to physiology than to medicine; for

* We have an ample account of the *iatro-chymical* sect in Sprengel, §. 13, ch. vi.; its advocates were numerous and respectable, but few were of that distinction which entitles them to be noticed in this sketch.

† Sprengel, §. 14. Cabanis, ch. 2, §. 9. In Italy we may select, as among the most eminent of the *iatro-mathematical* sect, Borelli, Bellini, Castelli, and Guglielmini; in France we have the celebrated Sauvages, and in our own country Pitcairne, Charleton, Keill, Jurin, Mead, and Freind; we may remark, however, that some of these, although practitioners of medicine, are principally indebted for their reputation to their physiological writings.

while it appeared to afford a satisfactory explanation of the phenomena of muscular contraction, of the circulation, and of the other functions in which motion was concerned, it was obviously less applicable to the explanation of the obscure and secret agencies by which diseased action is either produced or removed when present. It was, indeed, frequently employed by the pathologist to explain the proximate cause of disease and the operation of remedies, but, except in a few instances, it can scarcely be considered as having had much effect upon the actual treatment. For the most part the practice that was adopted by this sect was founded upon the principles of the humoral pathology, and may be said to have been fundamentally that of the Galenists, although with considerable additions, derived from the more energetic treatment and the enlarged materia medica of the Chymists. The great advantage which the science of medicine derived from the Mathematicians was of an indirect nature, depending upon the habit of close reasoning and strict deduction, which is requisite in all mathematical inquiries, and which, although in this instance incorrect in the application, and sometimes even founded upon a fallacious basis, were detailed with much labour and ingenuity, and tended both to improve the intellectual powers of the individual, and to raise the character of the medical profession.

During this period, while the minds of men were engaged in these controversies, and while so much attention was paid to theoretical reasoning, the practical part of the science was apt to be regarded as of secondary importance. Certain individuals, indeed, among whom Sydenham may be mentioned as a most illustrious example, contributed in an eminent degree to improve our knowledge of the phenomena of disease and of the effect of remedies upon it; but it must be confessed that, for the most part, medical men were more anxious to establish their favourite doctrines than to investigate the truth, and we find that, in the account which they give of the details of their practice, they appeared to be much more influenced by the desire of assimilating their experience to the tenets of their sect, than of inquiring how far these tenets were themselves sanctioned by their experience. In some instances there is too much reason to suspect that the operation of the theoretical views of the practitioner was decidedly unfavourable. The opinion which was entertained by the chymical physicians of the nature of fever, that it depended upon an acrid state of the fluids, led to the indiscriminate use of alkalies in all cases which were considered as belonging to this class of diseases. Again, certain hypothetical opinions which were entertained by the mathematical physicians respecting the mechanical condition of the blood, caused them to employ the lancet in cases where we should now consider it as decidedly injurious. But it does not require the illustration of particular facts to prove the position, that where the theoretical views which were entertained of the nature of the disease were incorrect, and where the practitioner was guided by these views, the result must have been frequently unfavourable. Happily, however, for mankind, there were not wanting individuals who rose superior to the spirit of the age, who disregarded the controversies of the contending sects, and who followed the inductive method of studying medicine which had now been introduced into philosophy by the commanding genius of Bacon. Besides Sydenham, our own country may justly boast of the names of Morton, Mead, and Freind,* who, although not without their bias towards particular opinions, were men of superior minds, who were fully aware of the imperfection of medical science, and of the value of experience, as the means of remedying this imperfection.

* For the character and writings of these eminent physicians the reader is referred to the respective articles in Eloy and Haller, *Bib. Med.*

CHAPTER X.

Account of the sect of the Vitalists—Van Helmont—Stahl, his system—Hoffmann, his system, pathology, influence of his doctrines—Solidism—Baglivi—Disciples of Stahl.

WHILE the medical world was thus divided between the rival opinions of the Chymists and the Mathematicians, a new sect was gradually rising up, which, although in its commencement it was perhaps equally remote from the principles of true science, became by successive improvements freed from many of its exceptionable parts, and finally triumphed over both the contending parties. It originated with Van Helmont, who commenced his philosophical career as a disciple of the chymical school of Paracelsus. He was a man of a powerful mind, but with a considerable mixture of enthusiasm, and even of fanaticism, who became disgusted with the Galenic mode of studying and practising medicine, and embraced the bolder and more efficacious system of the Chymists. But he made this great and essential addition to their doctrine,—that the changes which are produced in the body by its own spontaneous actions, as well as by the operation of remedies, are under the influence of a specific agent, which resides in or is attached to the living system, and to which he gave the name of *archeus*.*

It would not be easy to give any exact definition of the term, or to assign the precise meaning which was attached to it. Sometimes he seems to consider it as an abstract principle or power distinct from the material part of the universe; sometimes as a species of element, and at other times as a certain modification of matter which acquires peculiar qualities or agencies.† In consequence of his early training in the chymical school, he occasionally speaks of the *archeus* as a kind of ferment, and it would appear that he resolves all the operations of the living system and all the functions into certain fermentative processes effected by the action of the *archeus*. In short, the *archeus* was the convenient and never-failing aid to which he had recourse for the purpose of explaining all the actions of the system either in health or in disease; it was equally the cause of digestion and of sanguification, of fever and of inflammation. Van Helmont, both from the peculiar turn of his mind and from the course of study to which he had devoted himself, was little qualified to watch over the phenomena of disease, or to discriminate between the nice shades which so frequently serve to characterize the different morbid affections. Accordingly, it does not appear that he introduced any improvement into the practice of medicine, or indeed into any of the collateral departments; he is solely entitled to be noticed in this place as having laid the foundation for a new series of opinions, which were gradually moulded into one of the most important theories which had occupied the attention either of the physician or the physiologist.‡

Although, strictly speaking, Van Helmont must be regarded as the individual who first stated, in express terms, the great and important principle, that the living body possesses powers of a specific nature different from those which belong to inanimate matter, yet so much mysticism and error were mixed with it, that it produced little effect on the opinions of his contemporaries. Nearly half a century had elapsed after his death, during which time the physicians and physiologists were still defending the doctrines of the Chymists and the Mathematicians each against their respective antagonists, when a new impulse was given to medical theory by the appearance of the celebrated Stahl, who was born at Anspach in the

* He probably took the term from Paracelsus, who speaks of it as a new word which he had introduced into medicine; Chirurg. Mag. tract. 2. cap. 15.

† See the section of his "*Ortus Medicinæ*," entitled "*Archeus Faber*;" also Castelli's Lexicon, "*Archeus*."

‡ Floy, in loco. Haller, Bib. Med. lib. 8. t. ii. p. 518 et seq. Enfield, v. ii. p. 458-60. Goulin, Enc. Méth. Médecine, in loco. Sprengel, sect. 13. ch. 3; this author gives us a very minute analysis of the writings and opinions of Van Helmont. Although his absurdities are not concealed, I conceive that the account is somewhat too favourable. Hutchinson's Biog. Med. v. i. p. 414-423. Fournier, Biog. Univ. in loco.

year 1660. His education was almost exclusively occupied with the study of medicine. At the age of twenty-three he became a public lecturer, and from this time he bore a conspicuous rank in his profession, both as a teacher and a practitioner, during the remainder of his life. He was brought up in the principles of the chymical school, and hence his attention was early turned to the study of chymistry, in which science he effected a still greater revolution of opinion than in that of medicine. He possessed a character and disposition well adapted to become the founder of a new sect. He had great activity of mind united to great industry; he was zealous and enthusiastic, at the same time inclined to fanaticism and mystery; he was bold, confident, and arrogant, fully impressed with the importance of his own opinions, and disposed to place little reliance on those of others. His arrogance, however, probably induced him to enter upon investigations which he might not have attempted had he contented himself with following the track of his predecessors, and to his declared contempt for the learning of his contemporaries we may consider ourselves as in part at least indebted for his original speculations, and for the actual additions which he made to our knowledge. This contempt and arrogance were carried to such an extent, that he professed to set little or no value upon any of those studies that are usually associated with medicine, even that of anatomy; and he appeared to pay no regard either to the assertions or the arguments of his contemporaries, when they opposed any of his favourite doctrines. Besides his ardour in the pursuit of medical science, he appears to have had a decided turn for metaphysical reasoning, and in the formation of his theories he was probably influenced by the doctrines of Descartes, which were then embraced by many of the learned men of Europe.

Stahl saw the errors and deficiencies of both the prevailing theories; he therefore laid it down as a fundamental position, that neither chymical nor mechanical reasoning is applicable to the phenomena of life, and he consequently bestowed all his attention on the study of what he termed vital actions. These actions he refers to the operation of a principle which he styles *anima*, and which, in many respects, resembles the archeus of Van Helmont.* The basis of the Stahlian doctrine is similar to that of the Cartesian system, that matter is necessarily and essentially passive or inert, and that all its active properties or powers are derived from an immaterial animating principle, which is superinduced upon it or added to it. It is by the operation of this spiritual principle upon the material organs of the body that all the vital functions are produced, and it is on the absence or presence of this principle that the difference between living and dead matter essentially depends. Stahl observed with considerable acuteness the action which the mind exercises over the body, and he proved that these effects could not be referred either to a mere chymical or mechanical agent. This point, clear as it now appears to us, had not been distinctly recognised before his time, or, rather, it may be said that the contrary opinion formed the basis of both the prevailing theories. But although he laid down this great truth, and established it by incontrovertible arguments, there is considerable obscurity respecting the nature of this immaterial or superintending agent; and when we enter upon the detail of his description, we become involved in a labyrinth of metaphysical subtlety. We are told that the *anima* superintends and directs every part of the animal economy from its first formation; that it prevents or repairs injuries, counteracts the effects of morbid causes, or tends to remove them when actually present, yet that we are unconscious of its existence; and that, while it manifests every attribute of reason and design, it is devoid of these qualities, and is in fact a necessary and unintelligent agent. He examined with much attention the nature of the different functions, their relation to the *anima*, and their dependence upon it; he endeavoured to explain the effect of organization, and the mode in which organization operates in producing these functions. In these investigations he displays considerable acuteness, and he contributed materially to advance our knowledge of the laws of vitality; but still his ideas are, in many respects, confused and indistinct, and he is more disposed to enter into subtle disquisitions respecting the nature of his supposed principle, than to examine the actual phenomena of the animal economy, and from them to deduce his general laws.†

* Physiol. sect. 1. numb. 3. sect. 13, et alibi.

† Haller, Bib. Med. lib. xi. t. iii. p. 575 et seq. Eloy, in loco. Cullen, Preface to his "First Lines," p. 12-13. Sprengel, sect. 13. ch. i. t. v. p. 195-270. Blumenbach, §. 420. Thomson's Cullen, v. i. p. 161-132. Renaudin, Biog. Univ. in loco. Cuvier, Hist. des Scien. Nat. t. i. p. 216.

Contrary to what is frequently the case, the hypothesis of Stahl had a considerable influence upon his practice. As all the actions of the system are under the control of the anima, and as the office of this principle is to preserve the system in its perfect state, the duty of the physician is reduced to the mere superintendence of its actions, generally to co-operate with its efforts, or if they should be irregular or injurious, which we are to suppose is seldom the case, to endeavour to restrain or counteract them. These views tended to repress the energy of the practitioner still more than the pathological doctrines of Hippocrates, inasmuch as the anima of Stahl was conceived to exercise a more direct influence over the operations of the economy than the *φύσις* of Hippocrates, which was simply a general expression of these actions, and which, according to circumstances, might be either beneficial or injurious to the system. As a specimen of the mode in which Stahl applied his theory to practice, we may select his doctrine respecting plethora. He supposed that the body had a general tendency to the plethoric state, because he observed that spontaneous evacuations of various kinds occasionally took place, and these he assumed were produced by the provident care of the anima, in order to remove a plethora which must have previously existed so as to render them necessary. An important office of the superintendent principle is therefore to produce the necessary evacuations, in order to prevent or remove this plethora, and hence it becomes the duty of the practitioner to watch over the evacuations, to promote them if too scanty, or to repress them if too abundant.*

The theory of Stahl, so far as it tended to fix the attention upon the vital actions of the system, and to overthrow the mechanical hypotheses which had so long and so generally prevailed, may be considered as having performed an essential service to the science of medicine. The appearance of metaphysical acuteness which it presented, independent of its real merits, acquired for it a degree of popularity in an age when the attention had been particularly directed to subjects of this description. It certainly produced a considerable revolution both in medical language and in medical opinions; and although Stahl had but few followers, who received his doctrines in their full extent, it was partially embraced by many of the most intelligent and learned men of that period, and it has ultimately had a great and extensive influence on the state of the science. Independently of the defects inherent in the system itself, the spirit of inquiry was now so widely diffused, and the importance of patiently investigating the phenomena of the animal economy was so generally admitted, that the merits of all theories were more strictly canvassed, and subjected to more severe examination. From the same combination of causes, a variety of rival hypotheses were produced, which tended to prevent the exclusive adoption of any one of them in preference to the rest; and the same state of things was still further promoted by the great number of medical schools, which were established in all the great cities of Europe, each of which was anxious to advance its claim to the public attention.

We have given to Stahl the great merit of having clearly perceived and decisively established the important truth, that the operations of the animal economy cannot be explained by the laws either of chymistry or of mechanics, and that we must therefore have recourse to something of a specific nature, peculiar to the living system itself. Yet, although he succeeded in pointing out the insufficiency of the existing theories, the one which he substituted in their place, the action of the superintending anima, was no less difficult to comprehend, was equally hypothetical, and equally liable to objections. His genius was not of a kind which was adapted to slow and patient investigation, and we accordingly find, that he either defends his system upon general grounds, or rests satisfied with merely pointing out the errors and deficiencies of his adversaries. A powerful and sagacious mind was still wanting, which might carefully examine into the nature and operations of the powers that exclusively belong to the living body, and, after ascertaining the facts, might generalize them, and thus deduce the correct theory. This was a process of much labour and difficulty, one which could only be accomplished by slow degrees, and which it might be expected would require the co-operation of various individuals.

Of those whom we should be disposed to regard as having mainly contributed to this gradual progression, the first in point of time, as well as of celebrity, is Hoffmann. He was the contemporary of Stahl, and his colleague in the university

* Pathol pars ii. sect. i. mem. 2. § 3 et alibi.

of Halle; he may be considered likewise as his rival, for although they both contributed so considerably to advance our knowledge of the animal economy, and, to a certain extent, by pursuing a similar mode of reasoning, yet they were persons of very different habits and dispositions, and attempted to attain the same object by very different means. Hoffmann was a prolix and discursive writer, whose collected works occupy many folio volumes, and the very titles of which, as detailed by Haller, extend to no less than thirty-eight quarto pages.* It must therefore be supposed that they contain much that is of little value, and exhibit many marks of the hasty manner in which they were composed. Yet he appears to have been a diligent observer and collector of facts, and therefore, notwithstanding the repulsive aspect of his works, they are highly estimated and frequently referred to. He attended much more to the details of practice than his colleague, and, indeed, the basis of his great work, "*Systema Medicinæ Rationalis*," is essentially practical, in which his physiological and pathological doctrines are, for the most part, introduced in an incidental manner, as supporting or elucidating his practical observations. Of the nature or details of his practice it will not be necessary to enter into any minute examination. It did not differ very materially from that of his contemporaries, although the circumstance of his being less exclusively attached to any single hypothesis has rendered him more disposed to take a candid and unprejudiced view of the various points which would necessarily fall under his observation. In his leading doctrines he must be classed with the mathematical physicians, but at the same time he adopts many of the opinions of the Chymists, and indeed not unfrequently derives his indications from the supposed chymical condition of the fluids. But the great and important addition which Hoffmann made to theory, both medical and physiological, is the distinct manner in which he refers to the operations of the nervous system, and its influence on the phenomena of life. Many of the actions which Stahl ascribes to the action of his hypothetical principle, the *anima*, Hoffmann explained by referring them to the nervous influence, a physical power no less real than that of gravity or chymical affinity, but of a specific nature and operating by its own laws, the knowledge of which is to be acquired by observation and experiment.†

But whatever merit Hoffmann may have had as a practitioner, his reputation with posterity must principally rest upon his merits as a pathologist. Although, as we have stated above, he considered the fluids to be occasionally the primary seat of disease, yet in most cases he conceives it to originate in an affection of the solids. In order to explain this affection, he assumed that what he terms the moving fibre possesses a certain degree of action or tone, which constitutes its natural state, and is necessary for the performance of its functions. Various circumstances, as well external as internal, were supposed either to increase or diminish this tone; if it were increased beyond its true limit, the state of spasm is the result; if it were unduly diminished, the contrary state of atony was produced. This celebrated theory, which, under various modifications, entered so largely into the speculations of most of the pathologists of the seventeenth century, cannot be maintained in all its parts as it was detailed by Hoffmann; it must, however, be admitted that it made a considerable approach to a correct view of the subject, and that it may be regarded as the germ from which the more mature doctrines of his successors immediately emanated. It has been supposed that he borrowed it from the constricted and relaxed fibre of the ancients; but even if we admit that this may have furnished him with the first hint, it was so far new-modelled and extended by him as to deserve the merit of originality.‡

This hypothesis of the nature of the moving fibre, together with the more extensive influence which the nervous system was imagined to exercise over the various operations of the animal economy, may be considered as forming the basis of both the physiology and the pathology of Hoffmann. Unfortunately for the fame of this writer, in consequence of the multiplicity of his works, and the hasty manner in which they were composed, it is very difficult to obtain a consistent or connected view of his theory; but, upon the whole, I conceive that he is entitled to the merit of having materially advanced our knowledge of the laws of the ani-

* Haller, *Bib. Med.* t. iii. p. 536-576.

† Thomson's *Cullen*, p. 195, 6. Cuvier, t. i. ubi supra.

‡ Cullen, in the preface to his "*First Lines*," bears ample testimony to the value and importance of Hoffmann's physiological speculations, and acknowledges the use which he had made of them in the formation of his own hypotheses.

mal economy, and still more, of having pointed out the track which might be successfully pursued by others for the further advancement of this knowledge. With respect to the works of Hoffmann it may be further remarked, that as in the course of his experience he gradually enlarged and corrected his pathological doctrines, and continued to publish them from time to time in detached portions, but without giving them in a condensed or abstracted form, we frequently meet with what appear to be inconsistencies and contradictions, and are obliged to collect his opinions rather from inferences and from indirect remarks, than from any clear and explicit statement of them.*

In giving an account of the pathology of Hoffmann, I have somewhat anticipated an important point of medical theory to which we must now revert. I have had occasion in various parts of this history to notice, that through all the succession of opinions, from the time of Hippocrates to the period at which we are now arrived, with a very few exceptions, the hypotheses were all founded upon the humoral pathology. This opinion was maintained equally by the Mathematicians, the Chymists, and the Metaphysicians. The changes that were produced in the system, whether mechanical or chymical, were equally supposed to take their origin from the fluids, while the Metaphysician imagined that it was upon the fluids that his immaterial superintending principle exercised its action. We may regard the publication of Glisson's treatise, "*De Ventriculo et Intestinis*," which appeared in 1671, as having laid the foundation for the change of opinion which afterward took place respecting this doctrine. It was in this work that the hypothesis of muscular irritability was originally brought forward, a specific property, which is supposed to be attached to the living fibre, and from which is deduced its peculiar power of contraction.† But the first writer who systematically opposed the theory of the humoral pathology was Baglivi. He was born near the conclusion of the seventeenth century, and after rising to early eminence in his profession, and acquiring a high reputation for his sagacity in the treatment of disease, and for the assiduity which he displayed in the acquisition of medical knowledge, was prematurely cut off at the age of thirty-four.‡ He proceeded upon the Hippocratican plan of watching attentively and accurately describing the phenomena of disease; but he differed from him as to their primary seat, rejecting the principles of the humoral pathology, and placing the causes of them in the altered condition of the solids. His account of the nature of the solids, and the actions of what he terms the moving fibres, is by no means conformable to our modern notions on the subject, and may be pronounced to be incorrect; but the opinion that the fluids are affected secondarily, in consequence of a previous affection of the solids, was a great and important point of theory, which has been gradually gaining ground since the time that it was first promulgated by Baglivi, and may be regarded, with certain modifications, as the current hypothesis of the present day. The doctrine of solidism had, indeed, no direct or immediate effect upon the practice of medicine, but by drawing the attention more to the state of the muscular and nervous systems than to that of the fluids, it tended to correct many of the erroneous opinions which had previously prevailed respecting the actual condition of the system when labouring under disease, and in this way powerfully contributed to improve our knowledge of the relative state of the different parts of the animal economy, and of the operation of remedies upon it. The gradual subversion of the humoral pathology may also be regarded as a remote cause of the favourable reception with which the doctrines of Hoffmann were received, while the attention which he paid to the action of the nervous system contributed, in its turn, still further to favour the theory of solidism, in opposition to that of the humoral pathology.

The theory of Stahl, notwithstanding its defects and inconsistencies, was calculated to make a considerable impression upon the public mind at the time when it was advanced, and it accordingly met with numerous supporters. It clearly pointed out the inadequacy of all the previous hypotheses, founded merely

on mechanical principles, to explain the phenomena of vitality, while it was powerfully recommended by its simplicity; and perhaps even its metaphysical aspect might render it not the less acceptable to his countrymen, who were deeply interested in the speculations of Leibnitz, and the controversy to which they had given rise. It was not, indeed, generally embraced in its full extent; but with certain modifications it remained the favourite doctrine with many of the Germans, until it was gradually superseded by the more correct views of Hoffmann, and still further by the powerful and commanding genius of Haller.

Of the followers of Stahl, who adopted his opinions with the fewest alterations, we may select the names of Juncker and Alberti, who were both of them professors in the university of Halle, of which they contributed for many years to support the reputation which it had acquired under their illustrious predecessors. They were both of them voluminous writers, and they devoted a considerable part of their labours to expounding and illustrating the principles of the Stahlian system. But their works being more theoretical than practical, and being intended rather for the purpose of defending certain opinions than for the acquisition of knowledge, are now sunk into oblivion, or are merely referred to as historical records of an hypothesis which formerly engaged so much attention.

With these remarks on the theory of the Vitalists I shall close the review of the state of medical science during the sixteenth century. Up to this period I have adopted the chronological arrangement, and by pursuing this method have been enabled without difficulty to trace the successive stages of the progress of our art. But, as we approach nearer to our own times, the number of subjects which claim our notice are so multiplied, that it will be necessary to continue the historical sketch upon a different plan. Disregarding therefore, to a certain extent, the mere order of time, I shall, in succession, give an account of those individuals who have acquired the greatest degree of celebrity, endeavouring at the same time to class them according to the opinions which they adopted, pointing out their connection with each other, and with the general state of medical science.*

CHAPTER XI.

Introductory remarks—General progress of medical science—Boerhaave, character of his writings, his pathology—Gaubius—Gorter—Haller, his character, pathological doctrines, his disciples, his opponents—Whytt—Semi-animists—Sauvages—Cullen, his pathology and practice, his pupils—Brown, his system—Darwin, his system.

From the revival of letters to the commencement of the eighteenth century, including a period of between two and three hundred years, the great aim and object had been to apply to medicine the same scientific principles which had been found successful in the advancement of the other departments of philosophy. The most distinguished medical writers of that period had therefore employed themselves rather in collecting opinions and in reasoning upon them, than in examining into the grounds on which these opinions had been formed, or inquiring in what degree they were applicable to the explanation of the phenomena of the animal economy. For the most part, as I have had occasion to remark, they failed in their direct object; at the same time, however, a considerable body of information was gradually acquired, and the views which now began to be unfolded in consequence of the pathological speculations of Hoffmann, and the practical observations of Sydenham and the modern Hippocrateans, led to the establishment of the

* It may be necessary to observe that I have already somewhat deviated from the chronological arrangement in considering Hoffmann and Stahl as belonging to the seventeenth century, although it was not until near the close of it, in the year 1693 and 1694, that they entered upon their office as professors at Halle. But by admitting of this irregularity, I have made the division to correspond more nearly with the changes which took place in the state of medical science.

same spirit of inductive investigation in medicine which had been for some time adopted in the other departments of natural science. We have passed over the age of mere learning, and we now enter upon that of observation and experiment. Scholastic disquisitions were completely disregarded, abstract theory was rapidly falling into disrepute, and hypotheses were no longer considered as deserving of attention, unless they professed to be derived from the generalization of facts. The necessary result of this state of things has been to detach the mind from the arbitrary influence of theory, to diminish the authority of great names, and to induce the inquirers after truth to rest more upon their own exertions, than upon the authority of others. We have, indeed, still to lament the errors and perversions of the human mind, to witness the attempts of ignorance and arrogance to usurp the place which is due to modest desert and patient research; but such attempts, for the most part, have obtained only temporary success, and after an ephemeral celebrity have been consigned to their merited contempt. In the mean time notwithstanding these occasional interruptions, the progress of knowledge has been rapidly and steadily advancing. Experiments, well contrived and patiently conducted, have been performed in every department of physiological and medical science; observations have been made with more minuteness and recorded with more accuracy; our improved knowledge of chymistry has enabled us to introduce the most important reforms into pharmacy, while the discovery of various new articles of the *materia medica* has given us additional and powerful means of opposing the progress of disease.

While Stahl and Hoffmann were promulgating their doctrines in the university of Halle, the celebrated Boerhaave was teaching medicine with equal zeal, and, we may venture to say, with more success, at Leyden.* Boerhaave was originally educated for the profession of theology, but owing to some doctrinal scruples he fortunately relinquished his intention, and devoted himself to the study of medicine in all its branches. There are few examples, either in ancient or modern times, of any individual who arrived at higher eminence, both in general knowledge and in the departments more immediately connected with his profession. His acquaintance with botany and with chymistry were such as to enable him to teach both these sciences with the greatest success; while his lectures and his writings on medicine, both theoretical and practical, were long considered as standards of excellence. He had a mind and character peculiarly well adapted for his situation and the age in which he lived, when a variety of new facts and new hypotheses were brought into view, and when it required a consummate degree of judgment to weigh the opposing evidence, and decide between the merits of the contending parties. His moral qualities were no less admirable than his intellectual acquirements; and if we add to these his elegance as a writer, his eloquence as a lecturer, and his entire devotedness to his profession, we shall be at no loss to account for the celebrity which he enjoyed during his lifetime, and the reputation which he left behind him.

Boerhaave has been compared to Galen, and it may be asserted that he will not lose by the comparison. If Galen possessed more genius, Boerhaave possessed more judgment; while in their scientific acquirements, and in the extent of their information, it would not be easy to decide between them. They were both eminently skilled in the art of availing themselves of the knowledge of their contemporaries in all the branches of science, of applying it to the elucidation of their particular department, and of modelling and combining into a well-digested system all the scattered materials which they obtained from so great a variety of sources. In the stability of their systems, however, we observe a remarkable difference; for while Galen's doctrines were implicitly adopted for many centuries, the system of Boerhaave, notwithstanding its real merits and the applause which it obtained during the life of its inventor, shortly after his death was assailed from numerous quarters, and was unable to maintain its ground. The age in which Boerhaave lived was not one of authority, but of investigation, and the enlightened spirit which pervades his own works tended, in no small degree, to foster that taste for inquiry which led his contemporaries not to rest satisfied with his theories, however beautiful might be their aspect, and however happily they might appear to explain the phenomena of life, if they were found to be based upon principles which were themselves conjectural and gratuitous.

* Boerhaave was elected to the chair of medicine in 1709.

The great object of Boerhaave, in the formation of his system, was to collect all that was valuable from preceding writers, and by means of these materials to erect a system which should be truly eclectic. The basis of his doctrines is, in a great measure, mechanical, derived from the hypothesis of Bellini and Pitcairne; but he unites with this certain parts of the humoral pathology, and adopts some of the opinions of Hoffmann. To these he added various original observations, by which he has given ample proof of his talents as a sagacious practitioner. His language is remarkably perspicuous, and his reasoning, if we admit his premises, is fair and conclusive. But the grand error of Boerhaave consisted in his depending more upon opinions than upon observations; in his endeavouring to form a system which should be composed of the united speculations of others, rather than to ascertain the correctness of the principles from which these speculations were deduced. His system accordingly met with the fate of all such as are built upon hypothesis; it could not stand the test of experiment and observation, and, notwithstanding the efforts of some of Boerhaave's pupils, who were zealously attached to their master, it was generally discarded in no long period after the death of its inventor. But although the system of Boerhaave may have yielded to the more perfect and enlarged theories of his successors, he must ever be regarded as one to whom the science of medicine is deeply indebted. His Institutions and his Aphorisms would alone serve to immortalize his reputation as a correct observer and a sagacious practitioner; and if we compare them with any contemporary performance, which is the fair method of judging of the merits of the works of science, we cannot fail to recognise their own superiority.*

In forming his system, Boerhaave was not unmindful of the doctrines of Hoffmann, and particularly of the influence which the brain and nerves exercise over the operations of the animal economy. But although he introduces it on certain occasions, and in some instances allows it to act a prominent part,† yet he was by no means fully aware of the extent of its power. This indeed may be considered as the radical defect of his pathological doctrines; he regards the solids too much in the light of mere mechanical agents, without sufficiently taking into account those properties which specifically distinguish them from inanimate bodies. This deficiency was, to a certain extent, supplied by his nephew Kaul Boerhaave,‡ and by his favourite pupil and successor Gaubius,§ who introduced the agency of the nervous system in many cases where it had been omitted by Boerhaave himself. They were both of them men of considerable talents and acquirements, and the improvements which they made in medical theory were of real value. The writings of Gaubius, especially his Nosology and his Institutions of Pathology, were long held in high estimation, and were employed as text-books in the medical schools.|| In the same connection we may mention the name of Gorter, an eminent professor and practitioner of Harderwyck, who, while, like Boerhaave, he adopted the essential parts of the mechanical theories of his predecessors, made considerable use of the agency of what he termed the vital force in explaining many of the operations of the animal economy.¶ The writings of Gorter are very numerous, and prove him to have been an industrious cultivator of medical science, while his great practical work, entitled "*Compendium Medicinæ*," indicates a talent for correct observation, and an accurate discrimination of morbid symptoms.

But the great support and ornament of the Boerhaavian school was Van Swieten. He was born at Leyden in the last year of the seventeenth century, and was one of the most favoured and meritorious of the pupils of Boerhaave. In consequence of his theological opinions not coinciding with those of the state religion, he was expelled from the university of his native city, in which he held a professorship, and accepted an invitation from Maria Theresa to the court of Vienna. Here honours and distinctions of all kinds were heaped upon him; but these he amply

repaid by the unremitting attention with which he devoted himself to the medical school of that metropolis. Of the high reputation which it has since enjoyed he may be said to have laid the foundation, while, by the publication of his Commentaries on the Aphorisms of Boerhaave, he demonstrated, at the same time, the high respect which he retained for his preceptor, and the extent of his own information on all subjects connected with medical science. The Commentaries of Van Swieten contain a large and valuable collection of practical observations, partly the result of the author's own experience, and partly derived from his extensive knowledge of books. He adopted the theory of Boerhaave with little alteration, and in this respect the work must be regarded as fundamentally defective; but the great body of facts which it contains, detailed as they are in a clear and perspicuous style, will always ensure it a place in the library of the medical student.*

The intimate acquaintance which subsists between the doctrines of pathology and an acquaintance with the laws of the animal economy in its healthy and perfect state, makes it necessary for me to give some account of an individual, who, although not a practitioner of medicine, contributed perhaps more to our knowledge of the nature of disease than any one who has hitherto passed under our review. I refer to the great name of Haller, who has been not unaptly termed the father of modern physiology. He was the pupil of Boerhaave, and imbibed from him his thirst for knowledge, his correct judgment, his undeviating candour, his unblemished integrity, and, in short, all the intellectual and moral qualities which we have admired in the professor of Leyden. But to these qualities Haller added a more extensive and original genius, which led him never to rest upon the unexamined opinions of others, and a clearness of conception, which taught him, both in his language and in his mode of reasoning, to avoid all ambiguous and undefined terms, and all irrelevant arguments. He possessed a mind at the same time comprehensive and correct, equally adapted for discovering new paths to knowledge, and for investigating those which had been previously entered upon by others. The innate powers of the components of the body, which had been imperfectly seen by Glisson and by Hoffmann, were examined by Haller with his characteristic acuteness, and the result of his long and well-directed experimental research was rewarded by the establishment of his theory of irritability and sensibility, as specific properties attached respectively to the two great systems of the animal frame, the muscular and the nervous, to which, either separately or conjointly, may be referred all the phenomena of the living body. But perhaps a still more important service which Haller rendered to science was the example which he held out of carefully abstaining from all opinions founded merely upon speculative grounds, and of deducing his general principles exclusively from experiment and observation. He gave an impulse to science no less by the actual discoveries which he made, than by the spirit with which he conducted his researches, so that we may regard the publication of his Elements of Physiology as having introduced a new era into medical science.†

It would be incompatible both with the immediate subject of this essay, and with the limits to which it is necessarily restricted, to give a detailed account of the controversies and discussions to which the theory of Haller gave rise. Notwithstanding its merits, and the evidence by which it was supported, it was opposed, either in its full extent or in certain of its parts, by many individuals of high respectability; while, on the contrary, various experiments were instituted, by which his conclusions were confirmed and his principles extended. Among those who were the most successful in these researches I may select the names of Zimmerman,‡ Caldani,§ Fontana,|| Tissot,¶ Zinn,** and Verschuir. The last of these physiologists particularly distinguished himself by his experiments on the contractility of the arteries,†† a point which had been left undecided by Haller, but which formed a most important addition to the theory of the action of the vessels, and which had previously been rather assumed as what was probable, than deduced from any ascertained facts.

Whytt and Porterfield may perhaps be considered as the most powerful of the opponents of Haller. They were natives of Scotland, and during the earlier part of the last century, were residents in the metropolis of that kingdom, and bore a conspicuous part in the scientific institutions for which it was so justly celebrated. The former of them was professor of medicine in the university of Edinburgh, at the time when it was rapidly advancing to that high reputation which it afterward more fully attained, under the genius of his illustrious successor Cullen. They opposed that part of the theory of Haller which ascribes all the actions of the living system to certain powers necessarily connected with the material parts of the frame, as well as to the separation of these actions into the two distinct powers of irritability and sensibility.* The controversy which Whytt carried on with Haller was conducted with acuteness and ability, but it manifests a degree of acrimony which it is impossible not to regret, particularly as occurring in an individual who was otherwise so much entitled to our respect. And this is more especially the case when we consider the nature of the objections which he urged against the Hallerian hypothesis, which were rather of a metaphysical nature, than such as were either founded upon experiment or deduced from observation. His doctrine of the vital motions of the body, which formed the principal subject of the controversy, may be regarded as intermediate between that of Haller and Stahl, or rather compounded of the two. He attributes these vital motions to the operation of the sentient principle, which is supposed to be something distinct from the corporal frame, at the same time that it is necessarily attached to it, and is under the influence of physical causes, not like the anima of Stahl, acting by a species of independent consciousness and volition. The great error which pervades the speculations of Whytt and Porterfield consists in their reasoning more upon metaphysical than upon physical principles, and in their assuming certain powers, the proof of which rests more upon their supposed necessity to account for the actions of the system, than upon any independent evidence that we have of their existence. They did not, indeed, like the Stahlans, consider the sentient principle as something independent of the body, and only, as it were, appended to it, but as a principle or power necessarily belonging to the living body, and imparting to it its vitality, although essentially distinct in its nature from any of the properties of a mere material agent. Whytt may be regarded as the founder of the sect which obtained the name of the *Semianimists*, which, under various modifications, included some of the most distinguished physiologists both in this country and in France. Of the latter, one of the most eminent was *Sauvages*; he was a native of *Languedoc*, and received his education at *Montpellier*, which, during the early part of the eighteenth century, held a very high character as a school of medicine. In 1734, he was appointed one of the professors in the university of that city, and during the remainder of his life contributed materially to maintain its credit by his talents both as a writer and a teacher. His reputation with posterity will principally rest upon his *Methodical Nosology*, a work which contains an arrangement of diseases into classes, orders, genera, and species, on the same plan which had been employed in the arrangement of the subjects of natural history. The *Nosology of Sauvages* is a work of great and original merit, which, although now in some degree superseded by the improvements of later writers, mainly contributed to the advancement of medical knowledge by producing accuracy in the use of terms and in the discrimination of the characters of disease.†

The same kind of service which Haller rendered to the science of physiology was performed for that of the practice of medicine by his contemporary Cullen. Among those who have made the study of medicine their professed pursuit, no one, since the revival of letters, has risen to greater eminence during his lifetime, nor has left behind him a higher reputation than this celebrated individual. During the greatest part of a long life he was engaged in the teaching of medicine or some of the collateral sciences, first in the university of Glasgow, and afterward in that of Edinburgh, which latter he contributed, in no small degree, to raise to the rank which it long held, of the first medical school in Europe. His peculiar excellence as a lecturer afforded him an ample opportunity of promulgating and enforcing his doctrines, while their real merit, no less than the mode in which they were announced, rendered them in the highest degree popular among his

* See particularly Whytt on *Vital and Involuntary Motions*, and *Physiological Essays*. Porterfield on the *Eye*, *passim*, and papers in *Edinburgh Medical Essays*. Thomson's *Cullen*, v. i. p. 241-258.

† *Eloy*, in loco. Haller, *Bib. Anat.* "Boissier," t. ii. p. 300-4, §. 999.

pupils and contemporaries. He possessed an acute and ardent mind; he was well skilled in the medical literature both of the ancients and the moderns, but he had no undue respect for the opinions of others on the mere ground of authority. He detected the defects of former hypotheses with shrewdness and sagacity, while he proposed his own views with a degree of candour and modesty, which tended to render them the more acceptable, and disposed his audience to receive them in the same spirit with which they were proposed.

With respect to his physiological writings, they afford, in some respects, a remarkable contrast to those of Haller; for while the latter are extended to a great length, and are filled with the most minute and elaborate details, the former are no less remarkable for their compressed brevity, consisting principally in general views and abstracted deductions. Contrary, however, to what is so frequently the case with respect to works of this description, they are not to be regarded as mere speculative positions, but as the condensed result of patient research and extensive observation. Some of the leading doctrines of his pathology were professedly borrowed from Hoffmann; but to these he made many important additions, by taking advantage of the various improvements that had been made in physiological knowledge, principally by means of Haller and his pupils. Still later discoveries in this science, and in that of chymistry, have indeed proved that certain parts of his system are not tenable, and that others require to be considerably altered and modified; but it may be asserted, that no one produced a more powerful and lasting effect upon the state of medicine, in all its branches, both theoretical and practical, than Cullen. But his great and appropriate merit, and which entitles him to the admiration and gratitude of posterity, is the sagacity and diligence which he manifested in the description and discrimination of the phenomena of disease. In this talent he may be considered as rivalling Sydenham, or any of his most distinguished predecessors, while the recent improvements in physiology and the other branches of medical science gave him an advantage which he did not fail duly to improve. In his treatment of disease he manifested no less judgment and sagacity than in the formation of his theories. He was prompt and decisive, without rashness; he estimated the powers of remedies by a cautious and accurate examination of their effects, with little bias from hypothesis, and with even somewhat of a skeptical disposition of mind, which prevented him from falling into those errors and inconsistencies to which the practice of medicine is so peculiarly obnoxious.

In giving an account of the system of Boerhaave, we remarked that in its formation he proceeded upon the eclectic plan, founding it upon the opinions of others, which he endeavoured to connect together, and to mould into a consistent and uniform theory. Cullen adopted the more philosophical mode of generalization and induction. He disclaims all hypotheses and theories not derived immediately from facts, and made it his great business to collect, by actual observation, the materials from which he might deduce his general principles. In this object he was eminently successful, and it is this which gives his writings their great value, a value which they must ever retain, amid all the revolutions of opinion, which attach to medicine more than to any other branch of science. But, although he was so sensible of the advantage of the inductive mode of investigation, he was not a mere empirical practitioner, who disregarded all theoretical reasoning, and never ventured to go beyond the simple result of experience. On the contrary, he inquires in all cases into the remote and primary causes of disease, and endeavours to deduce from them his indications of cure. Many of his individual speculations are indeed remarkable for their subtilty and refinement, and may be characterized as exhibiting more ingenuity than judgment. At the same time it is not a little remarkable, that these speculations, however carefully they were elaborated, had but little influence on his practice; and it is gratifying to observe with what caution he applies his hypothesis to explain or direct his method of treating disease.

His great work, entitled, "First Lines of the Practice of Physic," is the one on which his reputation will principally rest; but the merits of his Institutions, of his Nosology, and of his Lectures on the *Materia Medica*, are each of them sufficient to have entitled him to a distinguished rank among the improvers of medical science. The last of these works, in which he takes a more philosophical view of the operation of remedies than had been done by any of his predecessors, is one of peculiar value. It contains a great variety of important pathological observations, together

with a complete theory of therapeutics, and being the latest of his publications, we find in it his more matured and corrected views on many topics which had been treated in his former works. In none of them do we find more of that spirit of rational skepticism to which I have alluded above, and which led him to be more confident in opposing the opinions of others than in maintaining his own. Like Haller, with whom I have already taken occasion both to compare and to contrast him, he contributed to introduce into medical reasoning a philosophical spirit, which has produced a permanent and highly salutary effect upon the healing art, and which associates the name of Cullen with those of the great benefactors of the human race.

It is not easy to give, in a short compass, an account of the pathological doctrines of Cullen, because they consisted rather of a number of individual parts, as applied to the explanation of particular phenomena, than of one comprehensive system, which constituted a general theory of diseased action. The foundation of the system is, however, sufficiently simple; that the living body consists of a number of organs, which are all of them possessed of powers of a specific and appropriate nature, distinct from those which are attached to inanimate matter. These powers are so ordered that they have a tendency to preserve the whole machine in a perfect state, when its actions and functions proceed in their ordinary course. When any irregularity supervenes, either from internal or external causes, if it be not in an excessive degree, the self-regulating principle is sufficient to control the operation of the morbid cause, and to restore the system to its healthy condition. This regulating principle, or, as it was termed, the *vis medicatrix nature*, differs essentially from the archeus of Van Helmont or the anima of Stahl, inasmuch as it is supposed not to be any thing superadded to the body, but one of the powers or properties necessary to its constitution as a living system, and the existence of which is recognised by its effects. Although the laws of gravity and of chymical affinity affect the animal body, so far as it is composed of material organs, yet its appropriate actions are under the immediate influence of the specific laws of vitality. Hence all explanations, depending upon mere mechanical or chymical reasoning, were abandoned, and in their place was substituted the vital action of the parts, and more especially that of the extreme branches of the arterial system, or, as they are styled, the capillary arteries. Although it may appear that both Stahl and Hoffmann had, to a certain extent, preoccupied the ground which was taken by Cullen, as to the foundation of his system, and although the system, as detailed by him, is defective in some of its subordinate parts, yet we must admit, that the ample and explicit manner in which it was stated gave it the aspect and much of the merit of novelty, while the applications which he made of it were frequently just, and always ingenious. His physiology and his chymistry were not in all cases correct; he did not pay sufficient attention to the distinction between the powers of the muscles and the nerves, which had been so well discriminated by Haller, and he even confounds their physical structure. But, with all these abatements, we still regard the pathology of Cullen with much respect, and consider him as one of those who greatly contributed to improve the science no less than the practice of his art.*

What may be termed the Cullenian school of medicine, including both his numerous pupils and the writers who either embraced his peculiar opinions or adopted his method of investigation, comprehends a large portion of the most distinguished of the British physicians during the remainder of the eighteenth century. The rational empiricism, as it has been styled, which he so firmly established, both by precept and example, has, in this country at least, so far superseded the taste for mere speculation and hypothesis, that we are, perhaps, disposed to run into the opposite extreme, and to undervalue all attempts to investigate the abstract principles of pathology, and to employ ourselves solely in the

* For a minute detail of the opinions of Cullen, and those of his immediate predecessors and contemporaries, the reader is referred to the learned and ample work of Dr. Thomson, which may be characterized as containing a philosophical history of medicine and pathology during the beginning and middle of the eighteenth century. The account which is given of Cullen's pupils must be perused with much interest—an interest which, in the case of the writer of this work, is exalted by the sacred sentiment of filial piety: p. 461, 644-6. I conceive that Sprengel, t. v. p. 359-366, in criticising the doctrines of Cullen, is somewhat deficient in that candour for which he is, in most cases, so conspicuous. See also Encyc. Brit. in loco; Aikin's Gen. Biog. in loco; Kerr, Brewster's Encyc. art. "Cullen."

accumulation of facts, without duly attending to the general conclusions that may be deduced from them.*

We have, however, to notice one singular exception to this remark, where an hypothesis was advanced, of the most bold and lofty pretensions, disdaining the support of facts and experience, and professing to explain all the phenomena of life and of disease by a few simple aphorisms. In tracing the history of science, although it is proper, for the most part, to estimate books and opinions solely by their intrinsic merit, without any regard to the personal character of the author, yet we find them, on some occasions, so intimately connected, that it is impossible altogether to separate them. This is the case with the celebrated Brown, whose theory appears to have originated as much from spleen and disappointment, and a determination to oppose the doctrines of Cullen, as from a more legitimate motive.

Neither the education of Brown nor his natural character were of the kind the best adapted for the prosecution of medical science. He was originally destined for the ecclesiastical profession; and when he afterward entered upon that of medicine, he never devoted himself to those elementary studies which are indispensably necessary to a correct knowledge either of theory or of practice. But what he wanted in knowledge he endeavoured to supply by the force of his own genius; and by meditating upon a few general or abstract principles, he ventured to form a new system of pathology, which he announced with a degree of confidence that, while it exhibited the strong powers of his understanding, proved no less the deficiency of his information. Medicine, which had hitherto been a conjectural art, was now to be built upon a few certain and fixed principles, which, by superseding all that had been previously written upon the subject, and by being independent both of observation and of experience, required for its attainment little previous study or learning. The novelty of the attempt, the easy access which it promised to a science which before appeared of difficult approach, and the plausibility of some of its leading positions, acquired for the new theory a prodigious degree of popularity in the university of Edinburgh, where it was first promulgated. Brown had been, in the first instance, patronised by Cullen; but, from *some causes*, both of a personal and a professional nature, which it is not difficult to comprehend, he forfeited the good opinion, and became the bitter antagonist of the doctrines of his former friend. The controversy to which this schism gave rise was carried on for some years with great vehemence, and was by no means confined to the place where it originated. In this country the Brunonian system obtained many adherents when it was first proposed, principally, indeed, among the students or younger members of the profession; while in some parts of the Continent, more especially in Italy, it was adopted by men of learning and science, and became the prevailing hypothesis in some of the most respectable medical schools.

The general principles of the theory are few and simple. He assumed that the living body possesses a specific property or power, termed excitability; that every thing which in any way affects the living body acts upon this power as an excitant or stimulant; that the effect of this operation, or excitement, when in its ordinary state, is to produce the natural and healthy condition of the functions; when excessive, it causes exhaustion, termed direct debility; when defective, it produces an accumulation of excitement, or what is termed indirect debility. All morbid action is conceived to depend upon one or other of these states of direct or indirect debility, and diseases are accordingly arranged in two great corresponding classes of sthenic or asthenic; while the treatment is solely directed to the general means for increasing or diminishing the excitement, without any regard to specific symptoms, or any consideration but that of degree, or any measure but that of quantity. Such general views and sweeping doctrines, however alluring to the uninformed

* In this brief sketch I can do no more than merely mention the names of some of our countrymen who, either by the publication of single cases, or of monographs on certain diseases, have contributed to the advancement of pathological or practical knowledge. Among others we may select those of Gregory, the able successor of Cullen, Pringle, M'Bride, Huxham, Fothergill, Cleghorn, Brocklesby, Lind, and Russel. In our own times, we have had the no less illustrious names of the Hunters, of Percival, Withering, Johnstone, Falconer, Heberden, Baillie, Haygarth, Ferriar, Currie, Willan, Bateman, Marcet, and Parry. In mentioning the name of Gregory, I must be allowed to express the sentiments of respect and regard which I have always felt for my preceptor. The elegance of his literary taste, his clear and comprehensive judgment, and more especially the interesting mode in which he conveyed his instruction, all contributed to render him one of the most distinguished ornaments of his profession.

or the mere theorist, are altogether inapplicable to practice; and it is a subject for our admiration how they could be for a moment entertained by any one who had studied the phenomena of disease, or who was acquainted with the intricate and complicated relations of the different functions and actions of the living system. Accordingly, in this country, where, in consequence of the prevalence of the Cullenian school, the attention was more directed to practical than to theoretical details, the professed adherents of Brown were neither numerous nor influential; and even in Italy, where for some time it enjoyed considerable popularity, it has long ceased to be maintained. Yet it must always occupy a distinguished place in the history of medical science, as exhibiting a remarkable example of the force of original and unaided genius in erecting a system, plausible and captivating in its aspect, but devoid of the essential support of facts and observations, and therefore fated to share the lot of all systems built on so unstable a basis.*

In connection with Brown I must notice a medical theorist, whose general principles bore a considerable resemblance to those of the "*Elementa Medicinæ*," but whose character, talents, and acquirements were of a totally opposite kind. The "*Zoonomia*" of Darwin exhibits genius and originality; but in no other respect does it bear any resemblance to its prototype. Darwin possessed a knowledge of medical and all the collateral sciences in their full extent; he was familiar with practice, and had a taste for minute detail and experimental research, which, while it appeared to qualify him for a medical theorist, enabled him to give to his system an imposing aspect of induction and generalization. His speculations, although highly refined, profess to be founded upon facts; and his arrangement and classification, although complicated, seem consistent in all their parts. No theory which had ever been offered to the public was more highly elaborated, and appeared to be more firmly supported by experience and observation, while every adventitious aid was given to it from the cultivated taste and extensive information of the writer. Yet the *Zoonomia* made little impression on public opinion; its leading doctrines rested rather upon metaphysical than upon physical considerations; its fundamental positions were found to be gratuitous, and many of the illustrations, although ingenious, were conceived to be inapplicable and inconclusive. It is now seldom referred to, except as a splendid monument of fruitless labour and misapplied learning.†

CHAPTER XII.

Remarks on the State of Practical Medicine at the Conclusion of the Eighteenth Century—State of Medicine in France, Lieutaud—State of Medicine in Germany, De Haën—State of Medicine in Italy, Morgagni, Burserius, Rasori—Epidemics—Improvements in Pharmacy.

WHILE the British physicians were principally occupied in collecting facts and recording their observations, and, with the exception of the temporary suspension which was occasioned by the Brunonian controversy, were more intent in adding to the stock of knowledge than in forming systems, the continental physicians were more disposed to pursue the eclectic plan of Boerhaave. In France this was accomplished with the most success by Lieutaud. He was a native of Provence, and was for some years a professor at Aix; in 1749 he was appointed physician to the royal hospital at Versailles, and finally to the court of France. He was eminent both as a practitioner and an anatomist; his great work, the "*Synopsis universæ Praxeos Medicæ*," published in 1765, contains much information

* Beddoes's Observations, prefixed to his edition of Brown's Elements; a writer possessed of originality and genius, but perhaps not unaptly characterized by Rothe as "a blind adherent of the new chymists and of Brown." M'Kenzie, in Brewster's Enc., art. "Brown." Parr's Dict., art. "Brunonian System." Aikin's Gen. Biog. in loco. Sprengel, t. vi. p. 155-158, 315-334. Suard, Biographie Universelle, in loco.

† Brewster's Enc., in loco. Sprengel, vol. vi. p. 269, 70, 278, 9. Young's Med. Lit., p. 54, 5. Brown's Remarks on the Zoonomia, an acute, but rather severe critique. Suard, Biographie Universelle, in loco.

on all topics connected with medicine, and is valuable from its real merits in this respect, while it is interesting as affording a correct view of the state of medical science in France at that period. With respect to his general principles, he was an eclectic, uniting certain parts of the old doctrines of the mathematicians and the humoralists with those of Hoffmann and the vitalists.* Upon the whole, however, I conceive that I shall not be accused of partiality or want of candour in stating the opinion, that the views of Lieutaud and his countrymen are less matured than those of his contemporaries in this island or in Holland. I may remark, in speaking of France, that for many years the great seat of medical science in that country was Montpellier. Its university was established in the thirteenth century, and was one of the earliest of those which rose to any considerable eminence; a distinction which it maintained until it was rivalled by that of Paris, which gradually acquired its splendid reputation during the course of the seventeenth century. To the name of Sauvages, who was mentioned above as distinguished for his learned work on nosology, we may add those of Bordeu, Barthez, and Astruc as among the most eminent members of the school of Montpellier.†

Of the medical schools of Germany, the most celebrated during the seventeenth and eighteenth centuries was Vienna. I have already mentioned the exertions that were so successfully made for its advancement by Van Swieten, who was appointed one of its professors in the year 1734. After he had occupied this situation for about twenty years, he associated with himself his countryman De Haën, who materially contributed to support the reputation of the university, particularly by his talents as a practitioner. His great work, entitled, "*Ratio Medendi*," is a valuable repository of facts and observations, upon which I may make the same remark that I offered above respecting Lieutaud's "*Synopsis*." De Haën has been characterized as a man of great learning, united with much practical skill, and a talent for correct observation; but, on the other hand, he appears to have been unreasonably prejudiced against new opinions, and even improvements, in his art; for not only was he one of the most zealous opponents of Haller's theory, but he was no less decided in his opposition to the practice of inoculation, and to the use of various new remedies, which were at that period introduced into medicine, the value of which is now generally recognised. The state of medical theory then prevailing in Vienna was nearly the same with that which was taught in the universities of Leyden and Paris; the doctrines of the humoral pathology may be considered as forming the basis of their hypotheses; but upon these was engrafted a certain portion of the new views respecting the action of the nervous system and the contractibility of the muscular fibre.

In Italy, which so early acquired a high degree of celebrity for its medical schools, and which still retains a considerable portion of its former reputation, the sciences of anatomy and physiology were cultivated with success, while they were but little attended to in the other parts of Europe. What may be styled anatomical pathology took its rise in Italy in the seventeenth century. The individual to whom the merit of having opened this new road to the improvement of medical knowledge is principally due is Bonet,‡ who was born at Geneva in 1620, and at an advanced period of his life published his great work, entitled "*Scapulchretum*," which was afterward enlarged by his learned and industrious countryman Manget.§ The *Scapulchretum* has been styled "*The Library of true Pathology*;" it consists of a great collection of cases, in which we have a history of the disease, with the appearances found upon dissection. The plan which had been commenced by Bonet and Manget was followed up by Valsalva, an eminent professor of Bologna, and still further perfected by the illustrious Morgagni. This eminent anatomist was a pupil of Valsalva's, and afterward became professor in the university of Padua, where for nearly sixty years, until his death, which took place in 1771, he devoted himself without intermission to the study of his favourite pursuit. The principal works of Morgagni are, his "*Adversaria Anatomica*," his "*Epistolæ Anatomicae*," and more especially his great pathological collection entitled "*De Sedibus et Causis Morborum per Anatomiam indagatis*." It proceeds

upon the plan of Bonct's Sepulchretum, and contains the observations which were made both by himself and by Valsalva, and has always been regarded as a repository of facts and observations on anatomy and pathology, unequalled in extent and accuracy.*

The Institutions of Burserius afford a favourable view of the state of medical science in Italy at this period. He was born at Trent in 1724; studied first at Padua, and afterward at Bologna; he was for some years a professor in the university of Pavia, and finally removed to Milan, where he died in 1785.† Burserius was rather an eclectic than an original theorist, but his work is much valued for the information which it contains, and much admired for the elegant manner in which the information is conveyed. Like his contemporaries in Holland, France, and Germany, his doctrines are essentially founded upon those of the humoralists, but to these he unites various parts of those of the solidists and vitalists, and has proved himself deserving of the praise, not only of learning, but of candour and judgment.

I have already had occasion to remark upon the effect which was produced in Italy by the theory of Brown; it was embraced by many of the learned men of that country, and for some time acquired a considerably greater ascendancy over public opinion than it possessed even in its native city. It was not only defended in their publications, but its doctrines were applied to practice, and it was not until their insufficiency had been detected by fatal experience that the delusion was removed.‡ At the conclusion of the eighteenth century it would seem that the medical theories of the Italians were considerably similar to those of the Cullenian school, and that the Italians, like the English physicians, were little disposed to form systems of medicine, but devoted themselves principally to the cultivation of anatomy and physiology, in addition to the more immediate studies of their profession.

In tracing the additions and improvements which the science of medicine received during the eighteenth century, I must not omit to notice the descriptions of new diseases, either those which were conceived to have actually originated during this period, if there were any such, or those which had not been previously discriminated with sufficient accuracy from others that in many respects resembled them. The various epidemics which, from some unascertained and unexplained causes, have at different times passed over large portions of the surface of the earth; the endemic diseases attached to particular situations, originating in some circumstances connected with the atmosphere, soil, or climate of certain districts, or in the occupation or mode of life of its inhabitants; and lastly, the contagious or infectious diseases, which have invaded entire cities or communities, from unknown, or at least obscure causes, and, after spreading destruction on all sides, have disappeared from causes equally unascertained.

The first of these classes, the epidemic diseases, were made an especial object of attention, in the latter part of the seventeenth century, by Sydenham, whose remarks on them are among the most interesting of his works; also by Morton and by Ramazzini: at a somewhat later period we have the valuable observations of Huxham, of Lancisi and Torti in Italy, and of Stoll at Vienna. The science has been much enriched by various descriptions of the diseases incident to the army and navy, among which we may particularly notice those of Pringle, Brocklesby, D. Monro, Hunter, Lind, Hillary, Blanc, Trotter, Larrey, and Desgenettes.§ The formidable disease which has been emphatically termed the Plague, as it appeared in London, the Low Countries, Marseilles, Moscow, and other parts of Europe, in the latter part of the seventeenth and the beginning of the eighteenth century, and as it still exists in Turkey, Egypt, and the adjoining countries,|| as well

† Vide Pref. ad Instit. Med. Prac. ed. Lips. 1787.

‡ Rasori of Genoa appears to have been the first who made his countrymen acquainted with the doctrines of Brown, of which he was a zealous adherent; subsequently, however, he found reason, from the result of experience, to change his opinions, and very candidly and honestly expressed his conviction of their erroneous tendency. An ample account of the pathological doctrines which are at present the most generally received in Italy, under the title of "Nuova Dottrina Italiana," may be found in the various publications of Tommasini, the learned professor of Bologna.

§ For a very complete list of works on these subjects, the reader is referred to the valuable work of Professor Ballingall on Military Surgery, p. 227 et seq.

|| Hecker's account of the "Black Death," which ravaged so large a portion of the globe in the

as the less formidable, although more extensive visitations of the influenza, have each had their historians; and it is truly gratifying to observe that, in most cases, the writers have been more anxious to collect facts and to obtain correct information, than to support any particular theoretical views.*

In reviewing the state of medical science during the eighteenth century, and tracing its gradual advancement, we are naturally led to remark upon the great additions which have been made to pharmacy, both in regard to the introduction of new articles into the *materia medica*, and the improvement that has taken place in the preparation of various substances, and the mode of their administration. It has been remarked, that in proportion as our knowledge of the virtues and qualities of medicines has been matured, our pharmacopœia has been simplified, both as to the number of articles employed and the mode of compounding them. Accordingly, if we compare the successive editions of the British pharmacopœias and dispensaries, we shall find that a number of superfluous and inert substances have been from time to time rejected, and that the complex formulæ of the older physicians have been reduced in the same proportion. At the same time some substances of real efficiency have been added, while the improvement in chymical science has enabled us to obtain the active principles of these substances in much more condensed and commodious forms. This remark may be illustrated by Peruvian bark, a remedy which for a long period afforded a fertile field for controversy, both as to its power over disease, the nature of its operation, and the mode of its administration. Practitioners have long been aware of the futility of most of the points which were the subject of so much warm and even acrimonious discussion, and are satisfied with recognising its value as a powerful curative agent in certain diseases, without endeavouring to discover the nature of the occult qualities on which its operation depends; while the chymist has lent his aid in pointing out a mode by which its active proximate principle may be procured, detached from the inert matter with which it is naturally combined. The skill of the modern chymist has likewise been most beneficially exercised on the metallic preparations; giving them more fixed and definite combinations, pointing out the modes by which they may be produced with more ease and certainty, and ascertaining the chymical relation which they bear to other substances, so as to indicate how they may be combined with them without decomposition, or even with an increase of their activity.

CHAPTER XIII.

Cursory Remarks on the State of Practical Medicine since the Commencement of the present Century—Difficulty of acquiring Medical Experience—State of Medicine in Great Britain—Pathologists of France—Physiologists of Germany—Medical Journals—Medical Societies—Schools of Medicine—Suggestions for the Improvement of Medical Science.

As the historian of medicine approaches nearer to his own times, he finds his path cumbered with almost insurmountable difficulties. The subject on which he has to treat differs, perhaps, from every other branch of science in this circumstance, that our actual information does not increase, in any degree, in proportion to our experience. Hence it follows that the accumulation of materials frequently rather retards than promotes its progress. In other sciences, although truth is not to be attained without a certain degree of laborious research, yet to those who are willing to bestow on it the requisite attention, it is, for the most part, attain-

fourteenth century, may be mentioned as a work worthy of our notice, both as containing many interesting details of this tremendous pestilence, and as exhibiting a curious specimen of medical hypothesis.

* For the names of the authors who have treated on these topics, I must refer to the respective articles in the *Cyclopædia of Medicine*. Copious lists of authors may also be found in *Young's Medical Literature*, a work no less remarkable for its learning than for the condensed form in which it is communicated. Much valuable information on this subject will be found in *Sprengel*, sect 16, ch. 3, art. 2.

able, or, if it still eludes our grasp, we are at least sensible of the deficiency, and can generally ascertain the precise nature of the obstacles which impede our progress. In other sciences, when we enter upon an inquiry, or propose to ourselves any definite object for experiment or observation, we are able to say whether the result of our inquiry has been satisfactory, and whether the object in view has or has not been accomplished.

But this is unfortunately not the case in medicine. There are certain peculiarities necessarily connected with the subject, which render it extremely difficult to appreciate the value of experiment and observation. In our experiments we are seldom able to ascertain with accuracy the previous state of the body on which we operate, and in our observations we are seldom able to ascertain what is the exact cause of the effect which we witness. The history of medicine in all its parts, and especially that of the *materia medica*, affords ample testimony to the truth of these remarks. In modern times, and more remarkably in Great Britain, no one thinks of proposing a new mode of practice without supporting it by the results of practical experience. The disease exists, the remedy is prescribed, and the disease is removed; we have no reason to doubt the veracity or the ability of the narrator; his favourable report induces his contemporaries to pursue the same means of cure, the same favourable result is obtained, and it appears impossible for any fact to be supported by more decisive testimony. Yet in the space of a few short years the boasted remedy has lost its virtue, the disease no longer yields to its power, while its place is supplied by some new remedy, which, like its predecessors, runs through the same career of expectation, success, and disappointment.

Let us apply these remarks to the case of fever, the disease which has been styled the touchstone of medical theory, and which may be pronounced to be its opprobrium. At the termination of the last century, while the doctrine of Cullen was generally embraced, typhus fever was called a disease of debility, and was of course to be cured by tonics and stimulants. No sooner was it ascertained to exist, than bark and wine were administered in as large doses as the patient could be induced, or was found able to take. No doubt was entertained of their power over the disease; the only question that caused any doubt in the mind of the practitioner was, whether the patient could bear the quantity that would be necessary for the cure.

To this treatment succeeded that of cold affusion. The high character and literary reputation of the individual who proposed this remedy, its simplicity and easy application, the candid spirit which was manifested, and the strong testimonials which were adduced by his contemporaries, bore down all opposition, and we flattered ourselves that we had at length subdued the formidable monster. But we were doomed to experience the ordinary process of disappointment; the practice, as usual, was found inefficient or injurious, and it was, after a short time, supplanted by the use of the lancet. But this practice was even more short-lived than either of its predecessors: and thus, in a space of less than forty years, we have gone through three revolutions of opinion with respect to our treatment of a disease of very frequent occurrence, and of the most decisive and urgent symptoms.

Are we, then, to conclude that all medical treatment is of no avail? that it is all imaginary or deceptive? I should feel most unwilling to be compelled to form such a conclusion, nor do I conceive that it necessarily follows from the premises; but the facts certainly prove the importance of extreme caution in forming our conclusions, and still more that mere experience, without the due combination of well regulated theory, is a most fallacious guide. What objection can the man of mere experience, the rejector of all theoretical deductions, urge against the multiplied testimony that is now presented to us in favour of the *Homœopathic doctrine*?—what answer can be made to the report that has been recently brought forward, by the medical commissioners of Paris, on the subject of *Animal Magnetism*? The conclusion that forces itself irresistibly on the mind is, that no medical testimony is sufficient to establish a fact which is in itself incredible, and that this previous incredibility can only be ascertained by an extensive and accurate knowledge of the functions and properties of the living body, both mental and corporal, in all its modifications and under all circumstances, and by a correct and careful generalization of the knowledge thus obtained. These considerations, as

well as others which will present themselves to the mind of the reader, may be deemed a sufficient reason for my attempting no more than to offer a few general observations on the state of medical science during the period at which I am now arrived. I shall therefore devote this chapter to some cursory remarks on the practice of medicine as it now exists in the different countries of Europe, as well as on the state of some of the collateral or auxiliary departments, and shall conclude by some suggestions for the best means for promoting its future progress.

The prevailing and predominant feeling of the most enlightened and the most judicious of the British practitioners during the period referred to, has been to place little value upon theory, and to devote their minds almost exclusively to the observation and collection of facts. There can be no doubt that this is a less injurious extreme than the opposite; but if the statement which has been made above be correct, it will probably be admitted that this system may be carried too far. And the same exclusiveness has also induced them to pay too little attention to some of the collateral departments of science. In pathology and in pharmaceutical chymistry they have been far outstripped by the French, and in physiology by the Germans. But at the same time that I feel it necessary to pass this judgment on my countrymen, I must fully admit that the spirit of rational empiricism, to which I have referred above as the characteristic feature of the Cullenian school, has produced a most beneficial influence on the general state of medical practice. If it has, on some occasions, produced fluctuation of opinion, and in others indecision or inertness, it has tended to sweep away much error, and to purify the science from many of the antiquated doctrines and practices that still maintain their ground among our continental brethren. This is more especially the case with our pharmacopœias, where, if we compare those of London and Paris, we shall be struck with the number of what we conceive to be useless articles that are still retained in the latter, sanctioned by the authority of the scientific and enlightened body of men who compose the medical faculty of the French metropolis. We are, however, indebted to France for the most important improvements which have taken place in pharmaceutical chymistry: by their method of obtaining the proximate principles of various vegetable substances, and the greater precision which they have introduced into the formation of the metallic preparations, they have conferred a great and lasting benefit on the art, which, among all the revolutions of opinions and practices, can never be countervailed.*

But the glory of French medical science is its pathology. We are justly proud of our Hunters, our Munros, and our Baillie; and there are certain individuals among our contemporaries who are emulously treading in their footsteps. But any feeling of national vanity which we might be disposed to indulge must be effectually repressed when we look at the illustrious band of French pathologists, when we review the labours of Pinel, Andral, Breschet, Broussais, Corvisart, Cruveilhier, Dupuytren, Laennec, Bayle, Louis, Gendrin, Foville, Chaussier, and others,† who have directed their attention more exclusively to pathology; and when we add to these the names of those who are to be regarded more in the light of physiologists, Bichat, Vie-d'Azyr, Cuvier, Richerand, Majendie, Edwards, Dumas, Legallois, Adelon, Demoulins, Serres, Blainville, Flourens, St. Hilaire, Dutrochet, and others, we must admit that France exhibits an unrivalled assemblage of medical philosophers. From the united labours of these eminent men it is impossible not to anticipate the most important results; but I believe that I am justified in asserting that, so far as the practice of medicine is concerned, the benefit is still rather in anticipation than in existence. With certain exceptions, but these no doubt very important ones, I should characterize the French practice as decidedly less effective than that of our country; dependence is placed on remedies which we

* We have a very learned review of the state of medicine during the early part of the present century from the pen of the celebrated Sprengel. It is peculiarly valuable, from the numerous references which it contains to the writers of Germany, and from the view that it presents of the opinions which prevail in that country. The German physiologists afford a singular admixture of profound investigation and fanciful mysticism.—Ed. Med. Journ. v. xii. p. 335 et seq. We have also an interesting sketch of the progress of the science by Cuvier; Hist. Scien. Nat. t. i. p. 311-344, and t. iv. p. 2303-44.

† I may refer my readers for an interesting account of the progress of pathology, since the commencement of the present century, to a series of papers in the Archives Générales de Médecine, by M. Dezeimeris, t. xxix. et seq. The "Dissertation" of Professor Alison, appended to the "Cyclopædia of Practical Medicine," contains an admirable view of the state of medical science generally during this period.

conceive to be inert, and much of the dietetic regimen which enters so largely into the treatment can produce no effect in the removal of disease. In short, their "médecine expectante," although it may be a less dangerous weapon in the hands of ignorance or presumption, is, in the same proportion, less powerful and beneficial when under the direction of skill and judgment.

If France is pre-eminent for its pathology, Germany is no less so for its physiology and its anatomy. The names of Camper, Blumenbach, Ludwig, Soëmmerring, Meckel, Wrisberg, Reil, Tiedemann, Wenzel, Sprengel, Jacobsen, Carus, Pfaff, Oken, Oslander, Ackermann, Rosenmüller, Gmelin, Walter, and Treviranus may be selected from many others, as among the most celebrated throughout Europe, and as having made most important additions to our knowledge on the subjects to which they have particularly directed their attention. Yet, in Germany as in France, the effect of this scientific co-operation on the practice of medicine is not yet fully experienced. The treatment of disease is perhaps not more effective than in France, while it is still more encumbered with complicated formulæ and with antiquated practices, which in this country have been discarded because they have been found useless or even injurious.* Italy, which so long took the lead in all scientific pursuits, now offers the aspect of a splendid ruin, where we occasionally meet with an illustrious name, such for example as those of Scarpa, Caldani, Mascagni, Rolando, Bellingeri, and Tommasini, but where medical science, if it has not retrograded, has at least remained stationary. The practice of medicine has, however, had some zealous cultivators; I have already remarked on the activity with which the Brunonian controversy was pursued, and the excitement which was then produced seems to have had a beneficial effect in rousing the dormant energy of the mind, of which some traces are still visible.

A circumstance which has materially contributed to the improvement of the knowledge of practical medicine is the publication of periodical works, whether in the form of journals or of the transactions of societies. They have brought before the public the daily occurrences and passing events in a commodious and interesting form, and thus by exciting attention to them, have tended both to diffuse and to increase our knowledge on these subjects. It is, however, very much to be regretted that so valuable a mode of communication should, in too many instances, be used as the medium of personal animosity, and that what ought to be employed for the promotion of the welfare of mankind should become a vehicle of the basest and the most malignant passions. On this point, as well as on the one referred to above, justice compels me to state that the French metropolis offers us an example by which we might profit, in the number, extent, and general character of its medical periodicals; and the same sentiment leads me to remark, that the medical periodicals of London are decidedly excelled by those of Edinburgh and Dublin.—Among the published transactions of medical societies, the Medico-Chirurgical may fairly be selected for our approbation; these, in the short space of about twenty-four years, have amounted to eighteen volumes, and have acquired a character which is too well established to require recommendation or sanction.

In connection with their transactions I may mention the effect of the societies themselves, which, when they are confined to subjects of medical science, must be highly beneficial. Perhaps no single institution has contributed more to the improvement of our profession than the Edinburgh Medical Society, which, for so long a period, has maintained a reputation that reflects the greatest credit, not merely on its members, but even on the university to which it is attached. It is, indeed, a remarkable and an honourable circumstance, that an association, principally composed of students and entirely conducted by them, should have proceeded for above half a century in so uniform a course of respectability; that during this period they should have admitted of free discussion, without deviating into licentiousness, and that amid the fluctuations to which such an association must necessarily be subject, successors have at all times been found able to direct its progress and qualified to support its reputation.

Another circumstance to which I must briefly advert, which is both the cause and the consequence of the progress of our art, is the improved state of medical schools of all descriptions, both those attached to universities or to public hospitals,

* In speaking of the practical writers of Germany, it would be unjust to omit the name of Frank, and not to acknowledge the obligation which he has conferred upon medical science. Among the pathologists, Hartmann of Vienna and Conradi of Göttingen are perhaps the best known in this country.

and those conducted by private individuals. By a very singular anomaly it has happened that, in this country, the highest medical honours have been hitherto conferred by those bodies who did not profess to give the requisite means for their attainment. This circumstance may, indeed, in one point of view be regarded as paying the highest compliment to the English universities; but I believe that a very general sentiment now prevails among their most respectable members that this anomaly ought no longer to be suffered to exist, and that medical honours ought to be bestowed upon those, and those only, who have gone through what may be considered a sufficient course of preparatory studies, and who are able to give satisfactory proof that they have taken the due advantage of the means of improvement presented to them. But whatever may have been wanting in the English universities has been long supplied by that of Edinburgh, and, at a later period, by those of Glasgow and Dublin. The great London hospitals, and some of the private schools, especially those of anatomy, have, for a number of years, possessed teachers of the highest talents, and most admirably qualified for their office; but our metropolis could not be said to hold out the means of a complete medical education previous to the establishment of the London University and the King's College. These rival schools, rivals as I trust they will always be only in the talents of their professors and the excellence of their arrangements, have each of them laid down an academical course of medical instruction, which appears to be complete in all its parts, and which must have the most salutary influence on the character and qualifications of the future members of the profession.

The perusal of the foregoing pages may, I hope, enable my readers to form a tolerably accurate conception of the progress of practical medicine, of the obstacles which it has had to encounter, of the degree in which it has overcome these obstacles, and of its present state of improvement. This I am not disposed to under-rate; but at the same time I must acknowledge, that when I reflect upon the immense mass which has been written on the subject, the result seems scarcely adequate to the labour that has been bestowed. I may, therefore, be pardoned if I offer a very few remarks on the means by which, as it appears to me, the object in view might be more effectually attained.

This, I conceive, should be attempted precisely upon the same plan as in other departments of science;—in the first place, by a more careful exposition of facts; and, secondly, by a more careful generalization of them. In medicine there are various circumstances which render it less easy to ascertain the facts than in most other cases. These depend partly on the nature of the subject, and partly on the situation and character of the observer. It was the shrewd remark of a learned professor that in medicine there are more false facts than false opinions. On all topics, either historical, scientific, or literary, mankind possess a strong avidity for the marvellous. From the constitution of the human mind, the love of novelty is one great principle by which the attention is excited and the intellectual powers are called into action. Hence, in a rude state of society, nearly the whole art of medicine consists in the dexterous employment of this agent, and hence it is still found the most effectual method of attracting the notice of the multitude, who are incapable of close reasoning or calm investigation.

Perhaps one of the most easy and at the same time the most effective means of counteracting this mischievous influence, would be never to receive the evidence for any medical facts upon the authority of a single individual. They should, if possible, emanate from associated bodies, either from public hospitals, medical schools, or societies, the officers of which may afford their united testimony to the alleged facts. Another point which appears to me of vital importance, and which bears essentially upon every department of medicine, is that nothing should be received without the name of the author. The custom of anonymous writing, which has of late increased to so great an extent, has produced the most unhappy effects, both on the state of medical science and on the character of its professors; it has given rise to a degraded and depraved taste, no less at variance with honour and honesty, than with the spirit of scientific research. I will venture to assert that no man ought to publish any statement or any opinion to which he would scruple to attach his name. It may occasionally happen that an individual of a timid or a modest disposition may, by this restriction, be deterred from detecting an error or controverting a train of false reasoning, but the loss which might by these means be incurred would be amply repaid by the greater authenticity and the greater correctness of our medical publications.

With respect to the second suggestion, the more accurate generalization of facts, when the facts themselves are fully substantiated,—this must be accomplished by the due exercise of judgment and sagacity, and can scarcely be directed by any general rules. I may remark, however, that one obvious mode of attaining this end is to arrange our insulated facts, as much as possible, in the form of statistical tables, by which we may readily observe their connection with or relation to each other, and may thus be prevented from forming a hasty or unauthorized conclusion, derived merely from single cases or individual observations.

Another important means of obtaining the object in view is to preserve great precision in the use of technical and scientific terms. How many controversies have occupied the mind for ages, and have filled almost innumerable volumes, which have essentially turned upon the definition of a word? How frequently have remedies been prescribed, not for the symptoms, but for the name of a disease? How frequently has an article of the *materia medica* been employed, not from an experience of its actual effects, but from some nominal property assigned to it by an imperfect analogy or imaginary quality? The means that have been proposed to check these aberrations, to rectify the above-mentioned errors, and to reduce medical science to its appropriate and correct limits, are indeed few and simple, and not of difficult application. But there is one essential requisite, without which they can be of no avail,—a mind disposed to the reception of truth, determined to follow it wherever it may lead the inquirer, united to a high sense of moral obligation, which may induce the medical practitioner to bear in mind that his profession is a deposit placed in his hands for the benefit of mankind, and that he incurs an awful degree of moral responsibility who abuses this sacred trust, or diverts it to a base or selfish purpose.

THE
STUDY OF MEDICINE.

TO

SIR HENRY HALFORD, BART.

M.D. F.R.S. F.A.S.

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, PHYSICIAN
TO THE KING,

THIS WORK

IS

INSCRIBED

AS

A TRIBUTE OF GRATITUDE AND FRIENDSHIP.

AUGUST VI, MDCCCXXII.

EDITOR'S PREFACE

TO

THE FOURTH ENGLISH EDITION.

WHEN the learned and very distinguished author of the "Study of Medicine," much to the regret of every lover of talent and worth, went to that bourn from which no traveller returns, he had already advanced a considerable way in preparations for a new edition of this his favourite production; one to which he had devoted a great portion of the latter part of his life. At the period of his death, he had revised all the five volumes, which the work then consisted of, and he had introduced into each of them numerous additional observations, tending to augment their utility and correctness. Various parts of the work, however, still demanded further attention, and none more so than its surgical articles. It was under these circumstances that I was requested by his family to make some arrangement with the booksellers, by which the third edition might be completed and published; and finding that Messrs. Underwood were ready to offer a fair consideration for the copy-right, if I would give my assistance as editor, terms were agreed upon, and the undertaking was finished towards the close of 1829. After the failure of Messrs. Underwood, the copy-right became the property of Messrs. Longman and Co.; and the third edition having been entirely disposed of, a fourth has been called for, on which much time and labour have been expended. Subsequently to the date of the last edition, as it is scarcely necessary to explain, various important contributions have been made to medical science, bearing very materially upon some of the doctrines inculcated in the "Study of Medicine," sometimes corroborating, and, in other instances, as must be confessed, invalidating, or even refuting them.

These stores of new and modern information, comprised in the writings of some of the most distinguished physiologists, pathologists, and medical practitioners of the present time, have been extensively resorted to for the correction and improvement of this system of physic. Whether I have exceeded the editorial functions, or whether too little or too much has been done, it is not for me, but the profession, to determine. One apprehension has constantly followed me in the task, namely, that of stepping over the bounds, within which every discreet editor ought to confine himself. On this account, I have not presumed to encroach upon the author's plan, which, whatever may be the defects in its execution, rests upon a solid foundation, and has the pleasing recommendation of originality. But although, with few exceptions, the arrangement of the subjects treated of has not been changed, I have sometimes ventured to express reasons for thinking some of them misplaced. With the same frankness, I have also stated the

considerations which have now and then inclined me not to adopt precisely the views entertained by the author on certain points in physiology, pathology, and the treatment of diseases. So far as my own knowledge extends, no celebrated writers on medicine have yet been able completely to avoid hypothesis ; and, if the present author has occasionally soared into the regions of conjecture, he has only imitated all the greatest of his predecessors. For such flights every man, conscious of the difficulties of medical science, and aware of the zeal, perseverance, and active mind of the late Dr. Good, will readily find an excuse. If the general tenour of the book is good ; if many parts of it are executed in a truly superior style (their matter being daily referred to as high authority on the subjects to which they relate, and this by authors and lecturers of acknowledged judgment), surely the imperfections of so difficult an undertaking will be indulgently disregarded by every liberal critic, and its genuine merit warmly admired. As a system of physic, adorned with learned research, it is, perhaps, unrivalled.

In this fourth edition, a great deal of new and interesting matter has been inserted, principally in the form of notes, in order to avoid taking too much liberty with the text, or mutilating the work in a degree that seemed to me unwarrantable. I may also observe, with respect to incorporations in the text, that they are marked in such a manner, that the reader will immediately perceive the passages for which my own character, and not that of Dr. Good, is responsible.

In the fourth volume will be found the particulars of an extraordinary case, under Mr. Thomas Law, of Penrith, in which innumerable portions of *tænia* have been voided, and still continue to be so, from the *meatus urinarius* ; the only instance, I believe, of such an occurrence on record. Some of the specimens I mean to transmit to the Museum of the Royal College of Surgeons, and others to that of the University of London.

S. COOPER.

7 Woburn Place, Russell Square,
Nov. 1st, 1834.

PREFACE
TO
THE FIRST EDITION.

THE object of the present work is to unite the different branches of medical science, which, when carried to any considerable extent, have hitherto, by most writers, been treated of separately, into a general system, so that the whole may be contemplated under a single view, and pursued under a common study. These branches are the following :—

- I. **PHYSIOLOGY**, or the doctrine of the natural action of the living principle.
- II. **PATHOLOGY**, or the doctrine of its morbid action.
- III. **NOSOLOGY**, or the doctrine of the classification of diseases.
- IV. **THERAPEUTICS**, or the doctrine of their treatment and cure.

All these are of high, if not of equal, importance. As it is impossible for a workman to set about restoring a machine to order, with any rational hope of success, without knowing the full extent and nature of the injury it has sustained, so is it equally impossible for him to acquire this knowledge, unless he has also a knowledge of the structure of the machine, and has studied its several parts methodically, and in reference to the bearing which one part has upon another.

It is this advantage of the study of one part in relation to another that constitutes, or should constitute, in the art of medicine, the basis of **NOSOLOGICAL ARRANGEMENT** ; for by grouping diseases, not arbitrarily, but in the order of connexion in which they make their appearance in different functions, and the organs on which those functions depend, it is almost impossible to obtain an insight into the nature of any one disease belonging to such groups, without obtaining some insight into the nature of the rest, or tracing out some of the laws of morbid action which are common to the whole.

If it be convenient to concentrate the diseases of the nervous department into one division, as has been attempted by many nosologists, and ably accomplished by Dr. Cullen, it is to be lamented that the same principle has not been allowed to pervade the whole of the nosological plan ; and that the diseases of the other chief departments of the animal frame have not been concentrated in the same way, instead of being scattered, as we too often find them, over different divisions of a classification that is itself perpetually shifting from one ground of arrangement to another : which in one division, as in the Synopsis of Dr. Cullen, by far the best of his day, is derived from the temperature of the body ; in a second, from its anatomical structure ; in a third, from its chymical depravities ; and in a fourth, from its topography : thus offering us in each division a new principle, and one that has no common clew, or analogy with the rest.

It was the hope of obtaining a clearer and more connected method than had

hitherto been studied in the schools of medicine, that induced the present author to turn his attention to this subject many years ago, and at length enabled him to submit to the public a System of Nosology founded entirely on a physiological basis, in which the diseases of the respective functions of the animal frame are connected in classes derived from those functions, and follow each other in the order in which physiologists have usually treated of them.

It was not, however, from a mere hope of obtaining a more exact and comprehensive synopsis of diseases that the author was induced to undertake this new arrangement, but with a view of employing it as a text-book for the collateral branches of the Art of Healing already adverted to, as soon as he should find leisure to enter upon them, and to which no other synopsis he was acquainted with seemed equally adapted.

This work was published in the beginning of 1817, under the title of a "Physiological System of Nosology, with a corrected and simplified Nomenclature;" and the favourable opinion which has been formed of it; its adoption as a text-book in various medical schools of high reputation in our own country, and on the continent; the application which has been made to the author by some of the oldest and most established lecturers of this metropolis to print a syllabus of its classification for the purpose of lecturing from; and, above all, the approbation which the Royal College of Physicians has bestowed upon it, by permitting it to be dedicated to that learned body, after having been circulated amidst the fellows of the college, under an express order of the late president, for an examination of its contents by every individual at his own house, are, he trusts, a sufficient apology for his adhering to his original intention, and taking this system, instead of any other, as the groundwork of the ensuing arrangement.

It is not necessary in the present place to enter into a minute explanation of the subordinate parts of this system, nor of the occasional changes in medical nomenclature which are to be found in it; and which a close attention to correctness and simplicity seemed to render indispensable. All these are fully illustrated in the Preliminary Dissertation to the volume of Nosology, which the author is desirous of having regarded as a part of the general design. An alteration in the distribution of one or two of the diseases, as originally laid down, may be noticed by an attentive eye in the present volumes. They are changes which have been made out of deference to the opinions of others, or from a maturer consideration of the subject by the author himself: but, upon the whole, they are too few and of too little importance to render it necessary to indicate them in the present place.

A pretty active spirit of *PHYSIOLOGY* will be found to pervade the entire work; but the author has, beyond this, availed himself of the advantage which his arrangement so readily allows, of prefixing to every class a summary of the most important laws and interesting discoveries of physiology that relate to, or can elucidate, the subjects which constitute its scope. And he has occasionally enriched the dissertation by a glance at the more striking analogies of the animal and even of the vegetable world at large, wherever they could add to the illustration.

In the *PATHOLOGICAL DEPARTMENT*, if the reader meet with an occasional development of new principles, a question as to several that have been long before the public, or a further extension of many that are well established, the author trusts that whatever doctrines are advanced will, at least, be found true to themselves, and form a digested system, operating in accordance through the entire work, in what way soever they may be affected by future investigations. He trusts it will also be found, that nothing is newly started for the mere sake of novelty, or controverted from a mere love of disputation; and that, whenever it has been his misfortune to differ from high authorities which have preceded him, he has done it

with the candour which should peculiarly characterize a liberal profession. His main object has been to explain to the student the different subjects that pass before him, and to illustrate them by analogies, instead of confining himself to a dry and wearisome history of morbid symptoms and operations.

In THERAPEUTICS the author has allowed himself a liberal range, and has, occasionally, introduced into his *Materia Medica*, substances that are highly esteemed abroad, though little valued or even known at home, or that seem, without reason, to have fallen into temporary disrepute. There are some practitioners who think that all the articles which are of real use in the cure of diseases lie within a small compass, and may be learned without burdening the memory. This remark may be allowed to those who are limited to a portable dispensary, as in travelling, or on shipboard; but when uttered under other circumstances, it savours less of wisdom than of indolence. If the pharmacopœias of former times were too voluminous, and were occasionally loaded with medicines of trifling importance, the lopping and topping that must hereupon ensue would make a destructive inroad upon their boundaries, and take from them much that is good as well as something that can be spared. We may easily, indeed, substitute one medicine for another, but it is very rarely that we can hereby obtain an integral representative; a remedy possessing not only the general but the particular qualities of that whose place is supplied, so as to be equally adapted to the exact state of the disease or the express character of the idiosyncrasy. Sir George Baker was engaged as reasonably and scientifically in examining into the virtues of the *cardamine pratensis*, or lady's smock, as Dr. Stoerck in proving, upon his own person, the violent powers of *colchicum* and *stramonium*. A common fate has, indeed, attended the whole of these experiments. From attracting and concentrating the attention of the public, the medicines to which they were directed became equally overvalued; were employed upon all occasions; produced frequent disappointment; and gradually fell into disuse. The *colchicum* has been fortunate enough to ascend once more to its full zenith of popularity; many efforts have been made on behalf of the *stramonium*; and the *cardamine*, though at present less successful than either of the others, still holds in abeyance its post in the established pharmacopœias, waiting for some lucky trial to bring it once more into general esteem.

A work erected upon scientific principles, should know nothing of these accidental reverses, and still less of the varying and too often capricious taste of the day. To judge by the sentiments of some writers, the reputation of the bark seems at present on the wane, while the seeds of the *croton tiglium*, after a long neglect, are again rising into notice. In the remedial part of the present work, the author has endeavoured to allow to every medicine its proper value, as far as he has been able to estimate it, whatever may have been the era of its credit; and as there can be no stronger ground for the study of botany, oryctology, or chymistry, than the advantage they afford to the art of healing, and as these are provinces cultivated in our own day by almost every one, he has felt himself called upon by the general voice of the times to range with some latitude over the medicinal stores afforded by art and nature, and to discriminate the respective properties of each, rather than to limit himself to a few leading productions, or to refer to the whole under the general divisions of stimulents, sedatives, and cathartics, or whatever other names may serve for a medicinal classification.

It is this, indeed, that after all must chiefly constitute the THERAPIA, or PRACTICE OF MEDICINE, to which every thing else, though of the utmost moment, is but introductory. "The First Lines" of Dr. Cullen, when read, as they were delivered, in connexion with his "Treatise on the *Materia Medica*," constitute the most important course of instruction that has ever, perhaps, been laid down and com-

pleted by the same individual. But for this purpose they must be read together, though they were not published together, nor for the express design of forming a contemporaneous study : for it is a singular fact, that the *First Lines of the Practice of Physic*, though full both of mind and of matter, of elaborate axioms and theoretical principles, contain little of what the title suggests ; while the *Treatise on the Materia Medica*, without making any pretensions to the subject, is altogether a practical work, replete with practical principles, and founded upon a practical investigation.

Whatever may be the theory or the practice advanced in the ensuing volumes, the author will generally be found to leave nothing upon trust ; but to support or illustrate his assertions by authorities which he has endeavoured to give, with some degree of copiousness, from ancient as well as modern times : so as to render the work in a certain sense a summary of the general history of medicine in most ages and countries.

To the labours of our own countrymen, however, he professes to be chiefly indebted for his supplies : to the illustrious dead and to the illustrious living : to all of whom he has conscientiously endeavoured to do justice, even where he has been under the misfortune of differing from any of them in opinion. With the former he can have no controversy ; and, with the latter, he has taken the most gratifying means of avoiding it, and at the same time of adding considerably to the value of his work, by submitting to the most distinguished of them, and especially to those with whom he has the honour of a personal acquaintance, the successive sheets of the work, while passing through the press, that contain a notice of their respective opinions or publications ; with a request that they would correct any incidental misstatement, or communicate any valuable hint that may since have occurred to them on the subject. It would occupy too much space to enumerate all the individuals to whom the author has been indebted for assistance of this kind : but there are several whose names the public ought to be made acquainted with, as adding, in no ordinary degree, to the authority of the work itself.

He has, in the first place, to return his very grateful thanks to the President of the Royal College of Physicians, without whose fostering encouragement his health and strength, considerably encroached upon by the laborious and unremitting study with which it has been necessary to prosecute the subject, would hardly have held out to its close ; and who has not only taken the trouble of examining the sheets that relate to his own valuable labours, but of watching the progress of the work generally, and of perusing many parts of it as they have issued from the press. He has next to offer his acknowledgments to his highly distinguished and venerable friend, Dr. Perceval, of Dublin ; who has been so kind as to favour him with a valuable manuscript series of notes, in the form of a running commentary, upon the entire volume of *Nosology*, in illustration of its definitions or opinions ; the whole of which will be found imbodied into the present work, with a reference to the real author in every instance. To the liberality of Sir James M^cGrigor he is indebted for important assistance on several occasions, and particularly for his munificent offer of a free and facilitated access to all the medical documents of the army, addressed to him as Director-General. To his kind friend, Sir John Webb, he is also largely indebted for similar assistance from the Ordnance Department, and particularly in respect to the subject of plague, upon which he has proved himself to be so perfectly conversant. The kindness of Dr. Baillie can never be erased from the author's memory ; but he has particularly to thank him on the present occasion for reviewing the article on spasmodic stricture of the rectum, as well as several others, which, without his previous labours, would not perhaps have been found in the present work, or have been found but very imperfectly.

To Dr. Latham he is under obligations on various accounts ; but, in the present work, he is especially indebted to him for his friendly revision of the article *paruria mellita*, or *diabetes*. The volumes will display abundant instances in which he has derived assistance from the comprehensive mind of Sir Gilbert Blane, but the friendliness with which he has consented to furnish him with a description of his own case, in a very singular and obstinate attack of prurigo, and to revise the statement when printed, demands an especial acknowledgment. To Dr. Bree the author is indebted for perusing the article on asthma, and his very liberal opinion on the same. To Dr. Young for a like attention to that on phthisis, and the valuable hints with which his opinion was accompanied. To Dr. Cooke, whose friendship he has experienced in many important instances, he is under a similar obligation for perusing, and, in a few instances, correcting the account of apoplexy and palsy : and to his excellent and judicious friend, Dr. James Johnson, for various hints concerning tropical diseases, and a perusal of some parts of the present volumes in which they are treated of.

The author has entered with a considerable degree of fulness into the different modifications of diseases, in order to adapt the work to foreign climates and stations as well as to domestic practice : for a system of medicine, to be complete, should be of universal application. To render it such, however, it is seldom necessary to do more than follow up the common diseases of a country into their respective varieties ; for the general laws of the morbid action of the living principle are as permanent and universal as those of its natural action, and a really new species of disease is, perhaps, as much a phenomenon as a really new species of plant or animal. We see all these infinitely diversified by accidental circumstances, and particularly the circumstances of habit and climate ; but the specific outlines are still preserved, and we are still capable of reducing them, under every disguise, to their proper relations, and of assigning them their proper posts. From a few nondescript skeletons occasionally found in the bowels of the earth, and particularly from the interesting museum of such established by M. Cuvier at Paris, we have reason to believe that a few species of animals have totally disappeared ; as we have also, from the classifications of recent naturalists compared with those of earlier times, that a few species are now in being which had no existence in remote ages. And, in like manner, while a few species of diseases are now no longer to be found which are described by earlier writers, a few seem to have supplied their place, which are comparatively of modern origin. Yet upon the whole, the march of nature is but little interfered with in either case ; and hence the prognostics and aphorisms of Hippocrates, the medical histories of Aretæus and Galen, of Rhazes and Avicenna, and the natural histories of Aristotle and Pliny, are transcripts of animal life in our own day, as well as in the times in which they were severally composed ; and form important subjects of modern as it is well known they did of ancient study. The extensive family of fevers and spasmodic affections are, in the main, the same now as they are represented in the most ancient writings that have descended to us ; the plague of Athens, as described by Thucydides, we shall find in the ensuing pages to be the prototype of what still occasionally takes place in Egypt and along the Barbary coast ; and even the leprosy of the Levitical law, so minutely described by Moses, will be found, when the passage is closely and accurately rendered, still to retain its hold in the East, and to exhibit even the very same modifications as are noticed by the Hebrew legislator, and have been intermediately assigned to it by Celsus.

TABLE OF CLASSIFICATION.

CLASS I. CÆLIACA.

DISEASES OF THE DIGESTIVE FUNCTION.

ORD. I. ENTERICA.

AFFECTING THE ALIMENTARY CANAL.

GEN. I. ODONTIA.

MISDENTITION.

- SPE. 1. O. DENTITIONIS.—*Teething.*
2. DOLOROSA.—*Toothache.*
3. STUPORIS.—*Tooth-edge.*
4. DEFORMIS.—*Deformity of the Teeth.*
5. EDENTULA.—*Toothlessness.*
6. INCRUSTANS.—*Tartar of the Teeth.*
7. EXCRESCENS.—*Excrecent Gums.*

II. PTYALISMUS.

PTYALISM.

- SPE. 1. P. ACUTUS.—*Salivation.*
2. INERS.—*Drivelling.*

III. DYSPHAGIA.

DYSPHAGIA.

- SPE. 1. D. CONSTRICTA.—*Constrictive Dysphagia.*
2. ATONICA.—*Atonic Dysphagia.*
3. GLOBOSA.—*Nervous Quinsy.*
4. UVULOSA.—*Uvular Dysphagia.*
5. LINGUOSA.—*Lingual Dysphagia.*
6. PHARYNGEA.—*Pharyngeal Dysphagia.*

IV. DIPSOSIS.

MORBID THIRST.

- SPE. 1. D. AVENS.—*Immoderate Thirst.*
2. EXPERS.—*Thirstlessness.*

V. LIMOSIS.

MORBID APPETITE.

- SPE. 1. L. AVENS.—*Voracity.*
2. EXPERS.—*Long Fasting.*
3. PICA.—*Depraved Appetite.*
4. CARDIALGIA.—*Heart-burn.*
5. FLATUS.—*Flatulence.*
6. EMESIS.—*Sickness. Vomiting.*
7. DYSPEPSIA.—*Indigestion.*

VI. COLICA.

COLIC.

- SPE. 1. C. ILEUS.—*Iliac Passion.*
2. RHACHIALGIA.—*Colic of Poitou. Painter's Colic.*
3. CIBARIA.—*Surfeit.*
4. FLATULENTA.—*Wind Colic.*
5. CONSTIPATA.—*Constipated Colic.*
6. CONSTRICTA.—*Constrictive Colic.*

VII. COPROSTASIS.

COSTIVENESS.

- SPE. 1. C. CONSTIPATA.—*Constipation.*
2. OBSTIPATA.—*Obstipation.*

CLASS I. CÆLIACA.

ORD. I. ENTERICA.

GEN. VIII. DIARRHŒA.

LOOSENESS.

- SPE. 1. D. FUSA.—*Feculent Looseness.*
2. BILIOSA.—*Bilious Looseness.*
3. MUCOSA.—*Mucous Looseness.*
4. ALBA.—*White Looseness.*
5. LIENTERIA.—*Lientery.*
6. SEROSA.—*Serous Looseness.*
7. TUBULARIS.—*Tubular Looseness.*

IX. CHOLERA

CHOLERA.

- SPE. 1. C. BILIOSA.—*Bilious Cholera.*
2. FLATULENTA.—*Wind Cholera.*
3. SPASMODICA.—*Spasmodic Cholera.*

X. ENTEROLITHUS.

INTESTINAL CONCRETIONS.

- SPE. 1. E. BEZOARDUS.—*Bezoar.*
2. CALCULUS.—*Intestinal Calculus.*
3. SCYBALUM.—*Scybalum.*

XI. HELMINTHIA.

WORMS.

- SPE. 1. H. ALVI.—*Alvine Worms.*
2. PODICIS.—*Anal Worms.*
3. ERRATICA.—*Erratic Worms.*

XII. PROCTICA.

DISEASES ABOUT THE ANUS.

- SPE. 1. P. SPASMODICA.—*Spasmodic Stricture of the Rectum.*
2. CALLOSA.—*Callous Stricture of the Rectum.*
3. TENESMUS.—*Tenesmus.*
4. MARISCA.—*Piles.*
5. EXANIA.—*Prolapse of the Fundament.*

ORD. II. SPLANCHNICA.

AFFECTING THE COLLATITIOUS VISCERA.

GEN. I. ICTERUS.

YELLOW JAUNDICE.

- SPE. 1. I. CHOLŒUS.—*Biliary Jaundice.*
2. CHOLOLITHICUS.—*Gallstone Jaundice.*
3. SPASMODICUS.—*Spasmodic Jaundice.*
4. HEPATICUS.—*Hepatic Jaundice.*
5. INFANTUM.—*Jaundice of Infants.*

II. MELÆNA.

MELÆNA.

- SPE. 1. M. CHOLŒA.—*Black or Green Jaundice.*
2. CRUENTA.—*Black Vomut.*

CLASS I. CÆLIACA.

ORD. II. SPLANCHNICA.

GEN. III. CHOLOLITHUS.
GALL-STONE.

- SPE. 1. C. QUIESCENS.—*Quiescent Gall-stone.*
2. MEANS.—*Passing of Gall-stones.*

IV. PARABYSMA.

VISCERAL TURGESCECE.

- SPE. 1. P. HEPATICUM.—*Turgescence of the Liver.*
2. SPLENICUM.—*Turgescence of the Spleen.*
3. PANCREATICUM.—*Turgescence of the Pancreas.*
4. MESENTERICUM.—*Turgescence of the Mesentery.*
5. INTESTINALE.—*Turgescence of the Intestines.*
6. OMENTALE.—*Turgescence of the Omentum.*
7. COMPLICATUM.—*Turgescence compounded of various organs.*

CLASS II. PNEUMATICA.

DISEASES OF THE RESPIRATORY FUNCTION.

ORD. I. PHONICA.

AFFECTING THE VOCAL AVENUES.

GEN. I. CORYZA.

RUNNING AT THE NOSE.

- SPE. 1. C. ENTONICA.—*Entonic Coryza.*
2. ATONICA.—*Atonic Coryza.*

II. POLYPUS.

POLYPUS.

- SPE. 1. P. ELASTICUS.—*Compressible Polypus.*
2. CORIACEUS.—*Cartilaginous Polypus.*

III. RHONCHUS.

RATTLING IN THE THROAT.

- SPE. 1. R. STERTOR.—*Snoring.*
2. CERCHNOS.—*Wheezing.*

IV. APHONIA.

DUMBNESS.

- SPE. 1. A. ELINGUIUM.—*Elingual Dumbness.*
2. ATONICA.—*Atonic Dumbness.*
3. SURDORUM.—*Deaf Dumbness.*

V. DYSPHONIA.

DISSONANT VOICE.

- SPE. 1. D. SUSURRANS.—*Whispering Voice.*
2. PUBERUM.—*Voice of Puberty.*
3. IMMODULATA.—*Immelodious Voice.*

VI. PSELLISMUS.

DISSONANT SPEECH.

- SPE. 1. P. BAMBALIA.—*Stammering.*
2. BLESTITAS.—*Mispronunciation.*

CLASS II. PNEUMATICA.

ORD. II. PNEUMONICA.

AFFECTING THE LUNGS, THEIR MEMBRANES, OR MOTIVE POWER.

GEN. I. BEX.

COUGH.

- SPE. 1. B. HUMIDA.—*Common or humid Cough.*
2. SICCA.—*Dry Cough.*
3. CONVULSIVA.—*Hooping-cough.*

II. LARYNGYSMUS.

LARYNGIC SUFFOCATION.

- SPE. 1. L. STRIDULUS.—*Stridulous Constriction of the Larynx.*

III. DYSPNŒA.

ANHELATION.

- SPE. 1. D. CHRONICA.—*Short Breath.*
2. EXACERBANS.—*Exacerbating Anhelation.*

IV. ASTHMA.

ASTHMA.

- SPE. 1. A. SICCCUM.—*Dry or Nervous Asthma.*
2. HUMIDUM.—*Humid or common Asthma.*

V. EPHIALTES.

INCUBUS.

- SPE. 1. E. VIGILANTIUM.—*Day-Mare.*
2. NOCTURNUS.—*Night-Mare.*

VI. STERNALGIA.

SUFFOCATIVE BREAST-PANG.

- SPE. 1. S. AMBULANTIUM.—*Acute Breast-Pang.*
2. CHRONICA.—*Chronic Breast-Pang.*

VII. PLEURALGIA.

PAIN IN THE SIDE.

- SPE. 1. P. ACUTA.—*Stitch.*
2. CHRONICA.—*Chronic Pain in the Side.*

CLASS III. HÆMATICA.

DISEASES OF THE SANGUINEOUS FUNCTION.

ORD. I. PYRETTICA.

FEVERS.

GEN. I. EPHEMERA.

DIARY FEVER.

- SPE. 1. E. MITIS.—*Mild Diary Fever.*
2. ACUTA.—*Acute Diary Fever.*
3. SUDATORIA.—*Sweating Fever.*

II. ANETUS.

INTERMITTING FEVER. AGUE.

- SPE. 1. A. QUOTIDIANUS.—*Quotidian Ague.*
2. TERTIANUS.—*Tertian Ague.*
3. QUARTANUS.—*Quartan Ague.*
4. ERRATICUS.—*Irregular Ague.*
5. COMPLICATUS.—*Complicated Ague.*

III. EPANETUS.

REMITTENT FEVER.

- SPE. 1. E. MITIS.—*Mild Remittent*

CLASS III. HÆMATICA.

ORD. I. PYRECTICA.

GEN. III. EPANETUS.

- SPE. 2. E. MALIGNUS.—*Malignant Remittent.**
 3. HECTICUS.—*Hectic Fever.*

IV. ENECIA.

CONTINUED FEVER.

- SPE. 1. E. CAUMA.—*Inflammatory Fever.*
 2. TYPHUS.—*Typhus Fever.*
 3. SYNOCHUS.—*Synochal Fever.*

ORD. II. PHLOGOTICA.

INFLAMMATIONS.

GEN. I. APOSTEMA.

APOSTEME.

- SPE. 1. A. COMMUNE.—*Common Aposteme.*
 2. PSOATICUM.—*Psoas Abscess.*
 3. HEPATICUM.—*Abscess of the Liver.*
 4. EMPYEMA.—*Lodgment of Matter in the Chest.*
 5. VOMICA.—*Vomica.*

II. PHLEGMONE.

PHLEGMON.

- SPE. 1. P. COMMUNIS.—*Common Phlegmon.*
 2. PARULIS.—*Gum-bile.*
 3. PAROTIDEA.—*Parotid Phlegmon.*
 4. MAMMÆ.—*Abscess of the Breast.*
 5. BUBO.—*Bubo.*
 6. PHIMOTICA.—*Phimotic Phlegmon.*

III. PHYMA.

TUBER.

- SPE. 1. P. HORDEOLUM.—*Sty.*
 2. FURUNCULUS.—*Bile.*
 3. SYCOSIS.—*Ficous Phyma.*
 4. ANTHRAX.—*Carbuncle.*

IV. IONTHUS.

WHELK.

- SPE. 1. I. VARUS.—*Stone-pock.*
 2. CORYMBYFER.—*Carbuncled Face. Rosy Drop.*

V. PHLYSIS.

PHLYSIS.

- SPE. 1. P. PARONYCHIA.—*Whitlow.*

VI. ERYTHEMA.

INFLAMMATORY BLUSH.

- SPE. 1. E. ŒDEMATOSUM.—*Edematous Erythema.*
 2. ERYSIPELATOSUM.—*Erysipelatous Erythema.*
 3. GANGRÆNOSUM.—*Gangrenous Erythema.*
 4. VESICULARE.—*Vesicular Erythema.*
 5. ANATOMICUM.—*Erythema from Dissection.*
 6. PERNIO.—*Chilblain.*
 7. INTERTRIGO.—*Fret.*

CLASS III. HÆMATICA.

ORD II. PHLOGOTICA.

GEN. VII. EMPRESMA.

VISCERAL INFLAMMATION.

- SPE. 1. E. CEPHALITIS.—*Inflammation of the Brain.**
 2. OTITIS.—*Earache.*
 3. PAROTITIS.—*Mumps.*
 4. PARISTHMITIS.—*Quinsy.*
 5. LARYNGITIS.—*Inflammation of the Larynx.*
 6. BRONCHLEMMITIS.—*Croup.*
 7. PNEUMONITIS.—*Peripneumony.*
 8. PLEURITIS.—*Pleurisy.*
 9. CARDITIS.—*Inflammation of the Heart.*
 10. PERITONITIS.—*Inflammation of the Peritonæum.*
 11. GASTRITIS.—*Inflammation of the Stomach.*
 12. ENTERITIS.—*Inflammation of the Bowels.*
 13. HEPATITIS.—*Inflammation of the Liver.*
 14. SPLENITIS.—*Inflammation of the Spleen.*
 15. NEPHRITIS.—*Inflammation of the Kidneys.*
 16. CYSTITIS.—*Inflammation of the Bladder.*
 17. HYSTERITIS.—*Inflammation of the Womb.*
 18. ORCHITIS.—*Inflammation of the Testicle.*

VIII. OPHTHALMIA.

OPHTHALMIA.

- SPE. 1. O. OPHTHALMITIS.—*Inflammation of the whole Eyeball.*
 2. EXTERNA.—*Inflammation of the external Tunics.*
 3. INTERNA.—*Inflammation of the internal Parts of the Eye.*
 4. STAPHYLOMA.—*Protuberant Eye.*
 5. ECTROPIUM.—*Everted Eyelid.*
 6. ENTROPIUM.—*Inverted Eyelid.*

IX. CATARRHUS.

CATARRH.

- SPE. 1. C. COMMUNIS.—*Cold in the Head or Chest.*
 2. EPIDEMICUS.—*Influenza.*

X. DYSENTERIA.

DYSENTERY.

- SPE. 1. D. ACUTA.—*Acute Dysentery.*
 2. CHRONICA.—*Chronic Dysentery.*

XI. BUCNEMIA.

TUMID LEG.

- SPE. 1. B. SPARGANOSIS.—*Puerperal Tumid Leg.*
 2. TROPICA.—*Tumid Leg of hot Climates.*

XII. ARTHROSIA.

ARTICULAR INFLAMMATION.

- SPE. 1. A. ACUTA.—*Acute Rheumatism.*

* α Autumnal Remittent. β Yellow Fever.
 γ Burning Remittent. δ Asthenic Remittent.
 VOL. I.—B

* α Brain Fever. β Acute Dropsy of the Head.

CLASS III. HÆMATICA.

ORD. II. PHLOGOTICA.

GEN. XII. ARTHROSIA.

- SPE. 2. A. CHRONICA.—*Chronic Rheumatism.*
 3. PODAGRA.—*Gout.*
 4. HYDARTHROS.—*White-swelling.*

ORD. III. EXANTHEMATICA.

ERUPTIVE FEVERS. EXANTHEMS.

GEN. I. ENANTHESIS.

RASH EXANTHEM.

- SPE. 1. E. ROSALIA.—*Scarlet Fever.*
 2. RUBEOLA.—*Measles.*
 3. URTICARIA.—*Nettle Rash.*

II. EMPHLYSIS.

ICHOROUS EXANTHEM.

- SPE. 1. E. MILIARIA.—*Miliary Fever.*
 2. APHTHA.—*Thrush.*
 3. VACCINIA.—*Cow-pox.*
 4. VARICELLA.—*Water-pox.*
 5. PEMPHIGUS.—*Vesicular, or Bladdery Fever.*
 6. ERYSIPELAS.—*St. Anthony's Fire.*

III. EMPYESIS.

PUSTULOUS EXANTHEM.

- SPE. 1. E. VARIOLA.—*Smallpox.*

IV. ANTHRACIA.

CARBUNCULAR EXANTHEM.

- SPE. 1. A. PESTIS.—*Plague.*
 2. RUBULA.—*Yaws.*

ORD. IV. DYSTHETICA.

CACHEXIES.

GEN. I. PLETHORA.

PLETHORA.

- SPE. 1. P. ENTONICA.—*Sanguine Plethora.*
 2. ATONICA.—*Serous Plethora.*

II. HÆMORRHAGIA.

HEMORRHAGE.

- SPE. 1. H. ENTONICA.—*Entonic Hemorrhage.*
 2. ATONICA.—*Atonic Hemorrhage.*

III. MARASMUS.

EMACIATION.

- SPE. 1. M. ATROPHIA.—*Atrophy.*
 2. ANHÆMIA.—*Ersanguinity.*
 3. CLIMACTERICUS.—*Decay of Nature.*
 4. TABES.—*Decline.*
 5. PHTHISIS.—*Consumption.*

IV. MELANOSIS.

MELANOSE.

- SPE. 1. M. TUBERCULARIS.—*Tubercular Melanose.*

V. STRUMA.

SCROFULA.

- SPE. 1. S. VULGARIS.—*King's Evil.*

VI. CARCINUS.

CANCER.

- SPE. 1. C. VULGARIS.—*Common Cancer.*

CLASS III. HÆMATICA.

ORD. IV. DYSTHETICA.

GEN. VII. LUES.

VENEREAL DISEASE.

- SPE. 1. L. SYPHILIS.—*Poz.*
 2. SYPHILODES.—*Bastard Poz.*

VIII. ELEPHANTIASIS.

ELEPHANT SKIN.

- SPE. 1. E. ARABICA.—*Arabian Elephantiasis. Black Leprosy.*
 2. ITALICA.—*Italian Elephantiasis.*
 3. ASTURIENSIS.—*Asturian Elephantiasis.*

IX. CATACAUSIS.

CATACAUSIS.

- SPE. 1. C. EBRIOSIS.—*Inebriate Catacausis.*

X. PORPHYRA.

SCURVY.

- SPE. 1. P. SIMPLEX.—*Petechial Scurvy.*
 2. HÆMORRHAGICA.—*Land Scurvy.*
 3. NAUTICA.—*Sea Scurvy.*

XI. EXANGIA.

EXANGIA.

- SPE. 1. E. ANEURISMA.—*Aneurism.*
 2. VARIX.—*Varix.*
 3. CYANIA.—*Blue-skin.*

XII. GANGRÆNA.

GANGRENE.

- SPE. 1. G. SPHACELUS.—*Mortification.*
 2. USTILAGINEA.—*Mildew Mortification.*
 3. NECROSIS.—*Dry Gangrene.*
 4. CARIES.—*Caries.*

XIII. ULCUS.

ULCER.

- SPE. 1. U. INCARNANS.—*Simple healing Ulcer.*
 2. VITIOSUM.—*Depraved Ulcer.*
 3. SINUOSUM.—*Sinuous Ulcer.*
 4. TUBERCULOSUM.—*Warty excrecent Ulcer.*
 5. CARIOSUM.—*Cariosus Ulcer.*

CLASS IV. NEUROTICA.

DISEASES OF THE NERVOUS FUNCTION.

ORD. I. PHRENICA.

AFFECTING THE INTELLECT.

GEN. I. ECPHRONIA.

INSANITY. CRAZINESS.

- SPE. 1. E. MELANCHOLIA.—*Melancholy.*
 2. MANIA.—*Madness.*

II. EMPATHEMA.

UNGOVERNABLE PASSION.

- SPE. 1. E. ENTONICUM.—*Impassioned Excitement.*
 2. ATONICUM.—*Impassioned Depression.*
 3. INANE.—*Hairbrained Passion.*

III. ALUSIA.

ILLUSION. HALLUCINATION.

- SPE. 1. A. ELATIO.—*Sentimentalism. Mental Extravagance*

CLASS IV. NEUROTICA.

ORD. I. PHRENICA.

GEN. III. ALUSIA.

- SPE. 2. A. HYPOCHONDRIAS.—*Hypo-*
chondrism. Low Spirits.

IV. APHELXIA.

REVERY.

- SPE. 1. A. SOCORS.—*Absence of Mind.*

2. INTENTA.—*Abstraction of*
Mind.

3. OTIOSA.—*Brown Study.*

V. PARONIRIA.

SLEEP DISTURBANCE.

- SPE. 1. P. AMBULANS.—*Sleep-walking.*

2. LOQUENS.—*Sleep-talking.*

3. SALAX.—*Night Pollution.*

VI. MORIA.

FATUITY.

- SPE. 1. M. IMBECILIS.—*Imbecility.*

2. DEMENS.—*Irrationality.*

ORD. II. ÆSTHETICA.

AFFECTING THE SENSATION.

GEN. I. PAROPSIS.

MORBID SIGHT.

- SPE. 1. P. LUCIFUGA.—*Night Sight.*

2. NOCTIFUGA.—*Day Sight.*

3. LONGINQUA.—*Long Sight.*

4. PROPINQUA.—*Short Sight.*

5. LATERALIS.—*Skew Sight.*

6. ILLUSORIA.—*False Sight.*

7. CALIGO.—*Opaque Cornea.*

8. GLAUCOSIS.—*Humoral Opa-*
city.

9. CATARACTA.—*Cataract.*

10. SYNIZESIS.—*Closed Pupil.*

11. AMAUROSIS.—*Drop Serene.*

12. STRABISMUS.—*Squinting.*

II. PARACUSIS.

MORBID HEARING.

- SPE. 1. P. ACRIS.—*Acrid Hearing.*

2. OBTUSA.—*Hardness of Hearing.*

3. PERVERSA.—*Perverse Hearing.*

4. DUPLICATA.—*Double Hearing.*

5. ILLUSORIA.—*Imaginary*
Sounds.

6. SURDITAS.—*Deafness.*

III. PAROSMIS.

MORBID SMELL.

- SPE. 1. P. ACRIS.—*Acrid Smell.*

2. OBTUSA.—*Obtuse Smell.*

3. EXPERS.—*Want of Smell.*

IV. PARAGEUSIS.

MORBID TASTE.

- SPE. 1. P. ACRIS.—*Acrid Taste.*

2. OBTUSA.—*Obtuse Taste.*

3. EXPERS.—*Want of Taste.*

V. PARAPSIS.

MORBID TOUCH.

- SPE. 1. P. ACRIS.—*Acrid Sense of Touch*
or general Feeling.

2. EXPERS.—*Insensibility of*
Touch or general Feeling.

3. ILLUSORIA.—*Illusory Sense*
of Touch or general Feeling.

VI. NEURALGIA.

NERVE-ACHE.

- SPE. 1. N. FACIEL.—*Nerve-ache of the*
Face.

CLASS IV. NEUROTICA.

ORD. II. ÆSTHETICA.

GEN. VI. NEURALGIA.

- SPE. 2. N. PEDIS.—*Nerve-ache of the Foot.*

3. MAMMÆ.—*Nerve-ache of the*
Breast.

ORD. III. CINETICA.

AFFECTING THE MUSCLES.

GEN. I. ENTASIA.

CONSTRUCTIVE SPASM.

- SPE. 1. E. PRIAPISMUS.—*Priapism.*

2. LOXIA.—*Wry Neck.*

3. RHACHYBIA.—*Muscular Dis-*
ortion of the Spine.

4. ARTICULARIS.—*Muscular*
Stiff-joint.

5. SYSTREMA.—*Cramp.*

6. TRISMUS.—*Locked-jaw.*

7. TETANUS.—*Tetanus.*

8. LYSSA.—*Rabies. Canine Mad-*
ness.

9. ACROTISMUS.—*Suppressed*
Pulse.

II. CLONUS.

CLONIC SPASM.

- SPE. 1. C. SINGULTUS.—*Hicough.*

2. STERNUTATIO.—*Sneezing.*

3. PALPITATIO.—*Palpitation.*

4. NICTITATIO.—*Twinkling of*
the Eyelids.

5. SUBSULTUS.—*Twitches of*
the Tendons.

6. PANDICULATIO.—*Stretch-*
ing.

III. SYNCLONUS.

SYNCLONIC SPASM.

- SPE. 1. S. TREMOR.—*Trembling.*

2. CHOREA.—*St. Vitus's Dance.*

3. BALLISMUS.—*Shaking Palsy.*

4. RAPHANIA.—*Raphania.*

5. BERIBERIA.—*Barbiers.*

ORD. IV. SYSTATICA.

AFFECTING SEVERAL, OR ALL THE SENSO-
RIAL POWERS, SIMULTANEOUSLY.

CLASS I. CÆLIACA.

DISEASES OF THE DIGESTIVE FUNCTION.

ORDER I.

ENTERICA.

DISEASES AFFECTING THE ALIMENTARY CANAL.

II.

SPLANCHNICA.

DISEASES AFFECTING THE COLLATITIOUS VISCERA.

CLASS I. PHYSIOLOGICAL PROEM.

ACCORDING to the physiological arrangement proposed in this work, the first class of diseases consists of those which primarily affect, or commence in, the digestive organs, and impede the digestive function. I say *primarily* affect these organs, because they may be affected in a secondary manner, by sympathy or induction, in consequence of diseases which originate elsewhere, and, on this account, do not belong to the present class.

Now, in order to obtain a clear idea of the nature of the diseases before us, it is necessary to have a distinct knowledge of the organs which are the seat of them, and of the function which they embrace. To follow up this inquiry into a very minute detail, is the joint province of anatomy, physiology, and animal chymistry; and a finished practitioner must derive his information from these three sources collectively, pursued through an extent of many volumes. But, for our immediate purpose, it may be sufficient to give a general view of the subject.

No animal function displays a greater diversity of means for its performance, than that of digestion: and, perhaps, the only point in which animals of all classes agree upon this subject, is in the possession of an internal canal or cavity, of some kind or other, into which the food is introduced, and prepared for nutrition: an agreement, regarded as one of the leading features, by which the animal structure is distinguished from the vegetable.

[Some form of an alimentary cavity is, perhaps, the best criterion of an animal hitherto suggested. Cuvier distinctly states, that he knows of no animal unprovided with such an organ.—(*Dict. des Sciences Méd.*, tom. ii. p. 145.) On the other hand, plants do not contain any large, separate, internal cavity for the reception of their nourishment, which they absorb by pores on their surface, and especially by their roots

and leaves. As the generality of animals possess the power of locomotion, they could not have roots, by which they would be fixed in one situation. Most of them take their supply of food at once, according to need and opportunity, carry it about with them, and digest it at their leisure. This object is fulfilled by an alimentary cavity, whose internal pores, for imbibing the nutriment, may be compared to vegetable roots, which take up food from the soil. Hence Boërhaave used to say, that animals have roots within them; and the villi of the small intestines, as furnishing the general frame with the nutriment applied to their absorbent mouths, are beautifully denominated by Béclard the radicles of animal life. A distinct alimentary cavity, generally having a reference to locomotion, is then, as Cuvier remarks, one of the most invariable characters of an animal. A single mouth, he says, which some naturalists have fixed upon as a criterion, and contrasted with the multiplicity of the pores of the roots of vegetables, is less constant; for some animals of the family of medusa have several mouths, yet only one common stomachic cavity.

The superior relative importance of the digestive organs in the animal economy is further illustrated by the fact, that the existence of parts of them may be traced in the early stages of the fœtus, long before any rudiment of the spinal marrow, brain, or heart, can be detected. In this instance we also find the principle confirmed, that parts, first formed, are most rarely wanting. Thus, monsters have been met with, which consisted of nothing more than an abdomen, more or less perfect; but the separate development of a head, or chest, has never been observed. Man may be so incompletely developed, as to approach the point constituting the full organization of certain lower animals, and to appear only as a mere digestive cavity.

But, simple as his organization may be, the zoophite, which exhibits a like simplicity, can live and reproduce itself, such organization being natural to it; but man must perish; for his existence, as a mere unfinished sketch of himself, would be a contravention of the laws of nature.*]

The alimentary cavity in man extends from the mouth through the whole range of the intestinal canal; and hence, its different parts are of very different diameters. In the mouth, where it commences, and in the pharynx, it is comparatively wide; it contracts in the œsophagus; then again widens to form the stomach, and afterward contracts again into the tube of the intestines. The intestinal tube itself is also of various diameters, in different parts of its extent, and it is chiefly on this diversity of magnitude that anatomists have established its divisions. Its general length is five or six times that of the man himself; and, in children, not less than ten or twelve times; [digestion in them being particularly active, from the greater supplies of nutriment required for growth and reparation. Meckel found the length of the small intestines very irregular in different persons, and that it varied from thirteen to twenty-seven feet, without any proportionate difference in the stature of the body. In some animals, the intestinal canal is imperforate, the dross of the food being rejected by the mouth. This was once supposed to be the case in the medicinal leech; but Cuvier, Blumenbach, and Carus, all agree, in opposition to Dumeril, that the leech has a minute anus, from which, however, only a little fecal matter is discharged, most of it being voided by the mouth. No anus has yet been satisfactorily detected in the tapeworm.—(*Carus's Comp. Anat.*, vol. ii. p. 15.) In the actinæ, one aperture combines the two offices of mouth and anus.]—(*Carus*, p. 3.)

In the human subject, the anus is sometimes imperforate at birth, with a preternatural outlet, formed in some neighbouring part or organ, to supply its place, in which case the feces have been discharged by the urethra, the vagina, the navel, or the groin. An extraordinary instance of such accommodation is that of a girl, who from birth was imperforate in the anus and meatus urinarius; in fact, in the whole division of the vulva; and who, to the age of fourteen, had regularly discharged her urine by the breasts, and her feces by a natural vomiting or rejection from the stomach.—(*Samml. Med. Wahrnehm.*, b. viii. p. 29.)

Generally speaking, the extent of the digestive cavity bears a relation to the nature of the aliments by which the individual is designed to be nourished. The less analogous these aliments are to the substance of the animal they are to recruit, the longer they must remain in the body, to undergo the changes that are to assimilate them. Hence, the intestinal tube of herbivorous animals is for the most part (for we still meet with exceptions) very long; or, in partic-

ular portions, exceedingly capacious; in various kinds remarkably complicated, and often double or triple. Thus, in the horse, the large intestines are of enormous size, and dilated into sacculi, while the cœcum is as capacious as the stomach. In the ruminant animals, besides the peculiar complexity of the stomach, the alimentary canal is twenty-seven times the length of the body. On the contrary, carnivorous animals have a short and straight canal; their food, being already of their own nature, containing a larger quantity of nourishment in less bulk, and hence demanding a smaller proportion of time and space to become fit for use. [In them every circumstance concurs to accelerate the passage of the alimentary matter. It undergoes no mastication; it is retained but a short time in the stomach; the intestine has no folds, nor valves; its diameter is small; and the whole canal, when compared to the body, is extremely short, being only as three or five to one. Whales, however, have a longer canal than other carnivorous mammalia, their stomach is complicated, and the intestine has longitudinal folds. Indeed, carnivorous mammalia, of aquatic habits, generally possess a considerable length of intestine; a point in which they differ from most other animals of that class. The shortness of the intestinal canal in the generality of fishes, is compensated by the length of time the food, which is usually animal, is detained in it. A perch has been observed to take food but once in ten days or a fortnight.—(*Home's Comp. Anat.*, p. 340.)

In omnivorous animals, the canal is not so long as it is in the herbivorous, nor so short as it is in the carnivorous. Thus, in the rat, its proportion to the body is as eight to one; in the pig, thirteen to one; and in man, six or seven to one. In him the diminution in length is compensated by the numerous valvulæ conniventes and the preparation of the food by cookery.—(*Blumenbach's Comp. Anat.*, p. 178.) The domestic cat, which eats bread as well as flesh, has an alimentary canal considerably longer than that of the wild cat.]

The digestive canal of man is less capacious and complex than that of most mammalia, which take only vegetable food; yet, larger and more complicated than that of other mammalia, which live entirely on flesh. Hence, man seems to be capable of subsisting either on animal or vegetable food; and, from the nature of his digestive as well as of various other organs, is better qualified for every diversity of aliment and climate than any other animal. Thus, many nations in a savage state live almost, perhaps altogether, on fruits and roots; as those of the yam, beet, and potato, the bread-fruit-tree, bread-nut (*brosimum alcastrum*), sweet-chestnut, banana, cabbage-tree, palm (*areca oleacea*), and meal-bark (*cycas circinalis*). Others live on raw animal flesh, or flesh of the coarsest kind, as that of one species at least of the walrus (*trichecus dudong*), the sea-bear, and seal-calf. The Greenlanders feed voraciously on the skin and fins of the nord-capon, and on the flesh of whales. Many African tribes are said

* Andral, *Anat. Pathol.*, t. ii. p. 131. The stomach is formed subsequently to the intestines, and is more frequently wanting.

to live on dead lions and hippopotami. Dogs are eaten in the South Sea islands, horses in Tartary, and cats in many parts as a substitute for rabbits. Among numerous tribes of savages, indeed, the flesh of man himself is still dressed for food: the custom may have been more extensive formerly than in the present day; but it still prevails in several of the Australasian isles, and is even exhibited in New-Zealand, where the inhabitants are nevertheless peculiarly intelligent, and disposed to adopt the manners of Europeans. The Hindoos subsist chiefly on rice and maize, and will not touch flesh of any kind. Many tribes of wandering or nomadic Moors on gums, principally gum seneca. The Kamtschadales, and the wretched inhabitants of the neighbouring shores, on fishes, or coarse fish-oil mixed into a paste with sawdust, or the rasped fibres of indigenous plants: while the more polished and luxurious nations of Europe live on solid and liquid foods of every description.* Yet, it should not be forgotten that, in Ireland and some other places, the only aliment subsisted upon in extensive and populous communities, whose poverty prevents them from obtaining any other, is the potato.

Man, therefore, is omnivorous; but he is not the only omnivorous animal in the world: for the great Author of nature is perpetually showing us that, though he operates by general principles, he is in every instance the lord, and not the slave, of his own laws. And hence, among quadrupeds, the swine, and, among insects, the ant (and more examples might be adduced if necessary), possess as omnivorous a power as man himself, and feed equally on the fleshy parts of animals, and on grain, and the sweet juices of plants. [In this respect, there is a power of accommodation, where it would not *à priori* be expected. Thus, certain animals which, from the structure of their digestive organs, are plainly designed to live entirely either on vegetable or animal food, will subsist, as a matter of necessity, altogether on the particular kind not intended for them by nature, especially when the change is made in a gradual manner. Thus, in the northern parts of Asia, where grain is scarce, horses and oxen are sometimes fed on fish. Spallanzani (*Expériences sur la Digestion*, c. 74 et 75) habituated an eagle to live on bread, and a pigeon on flesh. If fresh water mollusca are put at once into seawater, or seawater mollusca into fresh water, they perish; but, if the change be gradually made, they live very well.†]

* The diversified character of the aliment of man might be farther illustrated by the great variety of food used by certain tribes of the North American Indians, particularly those inhabiting the western regions on the borders of the Pacific Ocean.—D.

† *Ann. de Chimie*, &c. vol. ii. p. 32, and Blumenbach's *Physiology*, 4th edit. p. 309. Sometimes a long deviation from the natural food is followed by a change in the structure of the digestive organs: thus, after a seagull has lived for some time upon grain, the strength of its gizzard is increased. See Home, *Comp. Anat.*, vol. i. p. 354.

It is sometimes suspected, that no animal can derive nutriment from any material not containing a proportion of azote, one of the essential elements of the animal body, and existing in it far more largely than in plants. [This doctrine, however, must be incorrect, if spiders can live on sulphate of zinc (*Thomson's Annals of Philosophy*, vol. xii. p. 494), and the Otomacs eat little else some months in the year, than large quantities of earth. A sudden change from a diet of fully azotized substances, like meat, bread, &c., to one composed of vegetables containing little or no azote, certainly cannot always be borne by the human constitution with impunity. This was proved in the eastern part of France, in the year 1817, where the failure of the crops produced such a famine, that the poor were compelled to contend, as it were, with the beasts of the field, for whatever vegetable productions could be found. The consequences were general anasarca, interruption of the menses, a diminution of the ordinary number of conceptions by one half, as carefully estimated by parochial documents, and permanent injury of the health. Even the sudden return to the use of barley bread, after the continuance of this miserable regimen for three months, was found not to be unattended with peril.]—(*Gaspard, in Magendie's Jour.*, t. i. p. 237, &c.)

It has often been a question, whether the abundance of azote in animals is derived from the atmosphere, by respiration or absorption, or by both these processes; or whether it is produced by the action of life itself; or obtained from articles of food.

The experiments of M. Magendie favour the supposition, that the great source of azote in the animal body is the food; for, on feeding animals of various kinds on substances that contain no sensible portion of azote, as sugar, gum, olive-oil, and butter, together with distilled water, and confining them to this kind of diet, they gradually fell into a state of atrophy, and died. The secretions assumed the character of those of herbivorous animals, the food was digested, but the muscles were reduced to one sixth of their proper volume. It is singular, that all the animals before death exhibited an ulcer of the cornea, which sometimes spread through the membrane, and let out the humours of the eye.

[Haller observes that certain animals are destroyed by the use of sugar, although nutritious and salutary to others. In Stark's experiments, we have many examples of the indigestible nature of a diet composed of a single article, which was easily digested when mixed with other substances. In order to render M. Magendie's experiments unexceptionable, Dr. Bostock (*Physiology*, vol. ii. p. 467) thinks, that a diet should have been tried, composed of a mixture of substances destitute of nitrogen. In fact, M. Magendie himself admits, that the question is not yet settled, whether life can be long supported by the sole use of any one species of aliment, however nutritive.—(*Physiology*, p. 222, 2d edit.) At the same time, it deserves particular notice that, in 1750, a caravan of above one thousand Abyssinians, in consequence of having

consumed all their provisions, are alleged to have subsisted for two months entirely on gum-arabic, which happened to be among their merchandise.—(*Hasselquist, Voyages, &c. in the Levant*, p. 298.) If this be true, it proves that man can live on a single substance, which was found by Magendie to be insufficient nourishment even for dogs.]

In general, the length of the alimentary canal is greater in mammalia than in the subordinate classes. It diminishes successively in birds, amphibia, and fishes; being in some fishes even shorter than the body itself, which is never the case in the first three classes; and in insects and worms is so diversified, as almost to bid defiance to any kind of scientific arrangement; being, in many instances, short and narrow, as in the dragonfly (*libellula*); and in others, as proper hydatids and infusory worms, constituting the globular membrane in which the entire structure of the animal consists. [On the whole, a long and complicated intestinal tube denotes that the insect feeds on vegetables; while the contrary character indicates that its food is animal. So capricious has nature been in the lower beings that, in the animals of corals and sponges, the intestines of several individuals frequently communicate (*e. g.* in the animals of the *pennatula*, sea-feather), where the nutriment of all is derived from a common source.]—(*Carus's Comp. Anat.*, vol. i. p. 14.)

Attached to the cheeks in some quadrupeds, as the monkey and marmot tribes, is a pouch or pocket, which conveniently holds their spare food, or enables them to convey it to their winter hoards.

The mouth communicates with the stomach by the long, narrow, membranous, and muscular canal, denominated the œsophagus, or gullet. This in many animals is so dilatable, as to enable them to swallow animals more bulky than themselves. [In those carnivorous animals which swallow voraciously, as the wolf, it is very large; but in many herbivorous ones, of considerable size, and particularly such as ruminant, its muscular fibres are proportionably stronger, and capable of voluntary motion. The process of rumination implies a power of voluntary motion in the œsophagus; and indeed the influence of the will throughout the whole operation is incontestible. It is not confined to any particular time; since the animal can delay it, according to circumstances, when the paunch is quite full. In the occasional examples of the power of rumination in man, the operation is also found to be voluntary. The opening of the œsophagus into the stomach is marked by some differences, both with regard to its size and mode of termination: circumstances explaining why some animals, as the dog, easily vomit; while others, as the horse, are scarcely susceptible of this operation,* which, in the latter, is also partly hindered from taking place

through the mouth, by the complete manner in which this cavity can be separated from the gullet by the velum palati.]

We have not time to follow up these playful diversities of nature; and must confine ourselves to a brief glance at the general structure of the human stomach, to which the œsophagus conducts. This is situated on the left side of the diaphragm or midriff: in its figure it resembles the pouch of a bagpipe; its left end is most capacious; its upper side is concave, and its lower convex; the two orifices for receiving and discharging the food are situated in the upper part. In its substance it consists of three principal coats or layers, the external and internal of which are membranous, and the middle muscular. The internal coat, moreover, is lined with a villous or downy apparatus, and is extremely convoluted or wrinkled; the wrinkles increasing in size as the diameter of the stomach contracts. [Few parts are more largely supplied with bloodvessels than the stomach, and it not only partakes of the ganglionic nerves with the neighbouring viscera, but it likewise derives another supply of nerves from the spinal cord, and is distinguished from every other part, except the organs of sense, by having a pair of cerebral nerves almost entirely devoted to it, though it is situated at so great a distance from the brain.]—(*Bostock's Physiology*, vol. ii. p. 443.) In an adult it will commonly contain three pints, or rather more; [and, according to Soemmerring, when it is moderately distended, it will hold from five to eleven pints. In opening some carnivorous animals directly after death, a middle muscular constriction is noticed, dividing the organ imperfectly into two compartments. Sir Everard Home deems a similar constriction natural to the human subject, and dwells much upon it in his theory of digestion. Soemmerring occasionally noticed it in females, in whom he supposed it to be caused by the pressure of the central bone of their stays. According to Andral (*Anat. Pathol.* t. ii. p. 133), it is mostly the result of a change of texture, or of a contraction of the muscular coat, and sometimes a congenital imperfection. He conceives, that it indicates in man the first degree of tendency to the kind of division of the stomach distinctly manifested in some other animals. If, however, in him the stomach naturally consists but of a single cavity, without any constriction or partition, a division of that organ is not the less evinced in him by other circumstances. Thus, the structure of the mucous membrane is certainly not exactly alike in the splenic and pyloric portions of the stomach. Their functions are also quite as different, while they are still further distinguished by the relative frequency and even the nature of their alterations of texture. In some animals, the different organization of the two portions of the stomach is manifest to the eye: thus, in the horse, all the inside of the splenic portion is lined by a thick cuticle. The stomach of the negro is rounder and shorter

* Blumenbach's *Comp. Anat.*, pp. 82—87, 2d edit. When a horse is compelled to vomit, he makes such efforts with the abdominal muscles, that the pressure on the distended stomach sometimes bursts it, the rupture always taking place

towards its great curvature. See Andral, *Anat. Pathol.*, t. ii. p. 107.—EDITOR.

than that of the European; and a still more remarkable roundness exists in the stomachs of apes, as is represented in Daubenton's excellent plates.

With respect to the muscular fibres of the human stomach, the question is frequently agitated, whether they have any share or not in rejecting the contents of that viscus in the act of vomiting? M. Chirac gave a dog some corrosive sublimate on a piece of bread, which was almost immediately vomited up, though a violent retching afterward continued. In this state of things, the animal's abdomen was opened, and the peristaltic action of the stomach appeared to be so feeble, that Chirac was led to infer, that the expulsion of its contents could not be owing to it. Even when the experimenter's finger was applied to the stomach, while the retching was going on, it is said, that no contraction of this organ could be felt.—(*Hist. de l'Acad. des Sciences*, 1686.) Duverney also regarded the stomach as entirely passive in the act of vomiting. Mr. Hunter, if he did not go so far as the latter conclusion, certainly refers the chief part of the operation to the action of muscles.—(*Animal Economy*, p. 200, 2d edit.) This doctrine received corroboration from the experiments of M. Magendie. Two grains of tartarized antimony, dissolved in an ounce and a half of water, were introduced into a dog's crural vein. Nausea was quickly excited. The stomach was then made to protrude through a wound in the abdomen; when the spasm of retching was plainly seen to depend upon the action of the diaphragm and abdominal muscles; the stomach itself remained free from contraction, and its contents were not discharged. After the stomach had been returned into its natural situation again, so as to be capable of being acted upon by the above muscles, vomiting took place, and at the same time that viscus was felt with the finger to be relaxed. When the nervi vagi were divided, vomiting was not thereby prevented from being the consequence of the introduction of the tartarized antimony into the venous system; a fact, confirming the result of some experiments made long ago by Dr. Haighton. Neither was vomiting hindered from being produced by this use of tartarized antimony, when the abdominal muscles were removed, provided the linea alba remained entire, between which and the diaphragm the stomach was yet subjected to the necessary compression. When the phrenic nerves were cut, and the diaphragm was left with only a supply of nervous influence from a few filaments of the eleventh and twelfth dorsal nerves, it was so weakened, that it no longer duly antagonized the abdominal muscles, and vomiting could only take place in a feeble way. Perhaps, however, the most curious experiment was that in which M. Magendie removed the stomach, substituted for it a bladder communicating with the esophagus, and then threw the solution of tartarized antimony into a vein: even under these circumstances retching came on, and the contents of the bladder were vomited up.—(*Mém. sur le Vomissement et Physiol.*, t. ii. p. 133.) On the contrary, Lieutaud

and Haller looked upon the stomach as the chief agent, and Sir Charles Bell may be set down as on the same side of the question; and he adverts to a stomach in his possession, the coats of which are so thickened, that they could not be made to contract by the action of the muscular fibres, and consequently there was no vomiting.* Against Magendie's experiments, others are recorded by Maingault; as well as a most interesting case of malformation by Drs. Graves and Stokes,† which was attended with such a displacement of the stomach into the chest, that this viscus was entirely above the diaphragm, and beyond the reach of its contractions. Yet incessant vomiting occurred during the patient's illness; "a fact worth a thousand experiments, and which completely decides the question, that vomiting may be produced by the action of the stomach itself, unassisted by any external compressing force." On the whole, however, from the various facts which have been made out on the present topic, and to some of which we shall advert in the chapter on Limosis Emetis, it may be inferred, that, in ordinary vomiting, the contraction of the stomach itself is not essential, any more than the compression of the diaphragm and abdominal muscles under extraordinary circumstances.

Nothing can be more aptly contrived for the purpose of agitating, mixing, and presenting every portion of the alimentary mass to the surface, by which certain parts are to be absorbed, than is the whole structure of the small intestines. While their muscular fibres are calculated to produce a constant undulatory vermicular motion, these are loosely lined by the absorbing membrane, whose numerous plicæ and valves form a most extensive surface, with their villi erected, and even mixed, as it were, with the semifluid alimentary matter. Then the outside of these bowels consists of a smooth and constantly lubricated surface, greatly facilitating the motion of the different convolutions upon each other.]—(*Bright's Lectures, in Medical Gazette*, for June, 1833, p. 282.)

In the more perfect classes of animals, the division between the large and small intestines is distinctly indicated by a muscular valve, formed jointly of the coats of the colon and the ileum by a short natural intussusception of the terminating portion of the latter into the commencing portion of the former; the important

* *Anat. of the Human Body*, vol. iv. p. 54. When we come to limosis emetis, however, an instance will be mentioned of incessant vomiting, though the coats of the stomach were prodigiously thickened.—Ed.

† *Dublin Hospital Reports*, vol. v. 8vo., 1830. The mechanism of vomiting is yet a disputed point. Dr. Marshall Hall is led by his experiments to believe, that the contents of the thorax and abdomen are subjected to a sudden and almost spasmodic contraction of all the muscles of expiration, the larynx being closed, so that no air can escape from the chest. Dr. A. T. Thomson inclines to the same view, and considers vomiting as an expiratory effort, rendered abortive by the shut state of the glottis. See his *Elem. of Materia Med.*, &c. vol. ii. p. 193. 8vo. Lond., 1833.

use of which is to moderate the flow of the contents of the smaller intestines into the latter, and to prohibit a regurgitation of feces into the former. And hence we never meet with fecal matter in the stomach, except in cases in which this valve or sphincter has lost the whole or a considerable portion of its muscular power. In the hedgehog, and several other quadrupeds, the valve of the colon does not exist; and in a few others, as the sloth and armadillo, the cæcum is wanting. In birds, the rectum, at the termination of its canal, forms an oval or elongated pouch, called *bursa Fabricii*, from the name of its discoverer; and then expands into a cavity, which has been named cloaca, from its receiving the extremities of the ureters and genital organs and their secretions; so that the fluids from all these are discharged from one common emunctory. The same mechanism is extended to a few quadrupeds, as the *ornithorhynchus paradoxus*, and the *hystrix*: the penis of the male, and the horns of the uterus in the female, being equally lodged in its interior.—(Sir E. Home, in *Phil. Trans.*, 1802, pt. 1 and 2.)

Contributory to the function of digestion, performed in the stomach and the parts of the alimentary canal immediately adjoining to it, are several organs which lie near it, and are connected with it in a peculiar manner. Of these the chief are the pancreas, the liver, the spleen, and the omentum. The last two are less constantly found in the animal kingdom than the liver, to which they are by many physiologists supposed to be subservient. They generally become more obscure, or diminish in size, from quadrupeds to fishes: a remark that will equally apply to the pancreas, which upon the whole disappears sooner than the spleen. It is found in the shark and the skate; but, in other fishes, its place seems to be occupied and supplied by the cæcal appendices and pyloric cæca.

The largest and most important of all these organs is the liver, by which the bile is prepared, [and which, besides being supplied, like other parts of the body, with arteries, has a large quantity of venous blood constantly poured into it by the vena portæ, formed by the junction of the veins from many of the abdominal viscera, and ramifying, like an artery, in its substance. Thus, it has two sets of vessels going into it; and it has also two sets issuing from it; one, the vessels forming the hepatic vein; the other, the biliary ducts, uniting together to form the hepatic duct. In addition to all this apparatus, absorbents are distributed abundantly both to the surface and to the substance of the liver, and nerves from the hepatic plexus go to every part of it. Besides all these vessels and nerves, the liver contains a granulated substance, between the different portions of which a cellular tissue is interposed.]—(Bright, *Op. cit.*) It is the seat of a great variety of diseases, and appears to produce a very powerful effect on the blood itself, by the removal of several of its principles, independently of its office as a digestive organ. It descends, under some modification or other, from man to the

class of worms; and, in the snail and several other gasteropodous mollusca, is comparatively very large; but, in various kinds, is destitute of a gall-bladder, as well among quadrupeds, as birds, fishes, and worms; though this appendage is common to all the amphibia, many of which, as the salamander, have livers of great magnitude.

All these organs co-operate in digestion, though the peculiar effect produced by several of them is still a subject of inquiry. They present to our observation a variety of curious structures, which we shall notice more at large in treating respectively of their deviations from health; and their surface is covered by a membranous plate, or sheet, supposed by Haller to be of condensed cellular membrane. Bichat has divided the proper membranes of the animal frame into three kinds; serous, mucous, and fibrous. The first forms a common external coating for the viscera, whether substantial or hollow: it is possessed of few nerves, and is lubricated by a perpetually ascending halitus. The second, or mucous membranes, form an internal coating to the larger tubes and hollow viscera, mostly connected with the skin at their extremities, as the mouth, nostrils, œsophagus and intestines, the cavities of the urinary and the uterine systems. They are enriched with numerous nerves, and their structure is loaded with minute glands, which secrete a muculent fluid, with which the interior surface of the organs is constantly moistened. The third, or fibrous division of membranes, belongs to another set of organs, and consists of the dura mater, which lines the skull, the periosteum, the membranous expansions of the muscles, the capsules of the joints, and the sheaths of the tendons.

The solid materials of the food are usually first masticated and moistened in the mouth and fauces, and in this state are introduced into the stomach, where they are converted into a homogeneous pulp or paste, which is called chyme; they are then in this pulaceous form introduced into the duodenum, and, by an additional operation, transmuted into a fluid, often presenting a milky appearance, and denominated chyle; in which state they are absorbed or drunk up by thousands and tens of thousands of little mouths of very minute vessels, which are sparingly if at all found in the stomach, but which abound upon the interior surface of the small intestines into which the stomach empties itself. These vessels constitute a distinct part of the lymphatic system. From the frequently milky appearance of their contents, they are known by the name of lacteals; [but, as the chyle is not always white, perhaps a better name for them is chyloferous vessels.] They anastomose, or unite together gradually, and at length terminate in one or two common trunks, the chief of which is termed the thoracic duct, whose office is to convey the different streams thus collected from the alimentary canal, as well as from other parts of the body, to the sanguiferous system, to be still farther operated upon by the action of the heart and lungs.

[The saliva, or epittle, the fluid with which

the food is first blended in the mouth, is secreted by the salivary glands. According to Berzelius, its solid contents do not exceed seven in 1000 parts, the rest being water. The principal saline ingredient in it appears, from Tiedemann and Gmelin's analysis, to be muriate of potash; but the sulphate, phosphate, acetate, carbonate, and sulphocyanate of potash are likewise present in small quantity. The human saliva contains but little soda. All physiologists, in their account of the uses of the saliva, represent it as lubricating the aliment preparatory to deglutition; as bringing sapid bodies under the influence of the organ of taste; and as softening the food for digestion.

In the above sketch of digestion, the function of the lacteals or chyloferous vessels has been cursorily noticed. It must now be mentioned, that modern physiologists disagree about the extent of the office and power of these vessels. Thus, M. Magendie's experiments lead him to doubt, in opposition to the statements of Hunter, whether they ever absorb any thing but chyle; and it is one of his doctrines, that all other substances, and particularly drinks, are conveyed from the alimentary canal into the circulation by the veins. It is the villi of the intestines, he observes, formed in part by the origins of the veins which absorb all the liquids in the small intestines, except the chyle. From the commencement of absorption until its conclusion, the properties of those liquids are discoverable in the blood of the branches of the vena portæ, but not in the lymph, or chyle, till long after absorption has begun. Magendie's experiments also tend to prove, that they then reach the thoracic duct, not through the chyloferous vessels, but by the communication of the arteries with the lymphatics. The vena portæ, which is the trunk of all the veins of the digestive organs, divides and subdivides in the tissue of the liver. Now, certain other experiments, of which M. Magendie gives the particulars, induce him to conclude, that this arrangement in the human economy has the effect of mixing the matter, absorbed in the intestinal canal by the veins, intimately with the blood; and that, if large quantities of drink and other substances, not chyle, were to be at once transmitted to the source of the circulation by the thoracic duct, without having undergone a preliminary change in the liver, serious and fatal consequences would arise. The facts on which this reasoning is founded, are highly interesting.*

Sir Everard Home formerly entertained a particular theory, that fluids passed from the

stomach directly into the spleen. Though his observations disagree very much with those of Magendie, they corroborate one point maintained by the latter physiologist, namely, that fluids pass from the alimentary canal into the circulation by some other channel than that of the chyloferous vessels. Strong arguments against Sir Everard Home's particular theory are deducible from the fact, that, if it were true, animals certainly could not exist, or even enjoy good health, without a spleen. Sometimes the spleen is wanting in man (*Licutaud*, tom. i., p. 234); and sometimes it has been removed from animals, which recovered and lived very well.—(*Th. Bartholini, Anatomy*, p. 155. *Mayo's Outlines of Physiology*, p. 142.) The hypothesis also appears to be scarcely consistent with what happens in the horse, whose stomach, which is small in proportion to the size of the animal, could not contain the immense quantity of hay, grass, oats, and water, often consumed in a very short time; and from which organ, Professor Coleman has ascertained by experiments, that the passage of drink along the intestines is sometimes equal to the rate of ten feet in a minute.]

The means by which the food is broken down into pulp, after being received into the stomach, are various. In the first place, the muscular tunic of the stomach acts upon it by a slight contraction of its fibres; and, in connexion with a certain degree of pressure, derived from the surrounding organs, produces, so far as this cause operates, a mechanical resolution. Secondly, the high temperature in the stomach produces a concoctive resolution. And, thirdly, the stomach itself secretes and pours forth from the mouths of its minute arteries a very powerful solvent, which is by far the chief agent in the process, and thus effects a chymical resolution. In this manner, the moistened and masticated food is converted into chyme. It then passes into the duodenum, and becomes mixed with the secretions poured into this organ from the pancreas, the liver, and the duodenum itself, and subject to their action; and hence its conversion into chyle.

The whole process of digestion, therefore, as it occurs in the human body, to which the description now given chiefly applies, consists of three acts; mastication, or chewing, chymification, and chylification.

Many substances are so hard and intractable as to sustain the action of the digestive organs without any other change, than that of being softened or otherwise partially affected, instead of being entirely subacted, and reduced to chyme or chyle. Such especially are the seeds of plants: and it is well worth observing, that, while birds or other animals derive from this kind of food a valuable nutriment, notwithstanding its passing through them without being completely digested, the seeds themselves, that are thus acted upon, derive also a reciprocal benefit in many instances; and are hereby rendered more easily capable of expanding in the soil into which they are afterward thrown as by accident, and have their productive power

* The views of Haller, Hunter, Musgrave, and others, in regard to the absorption of foreign substances by the lacteals, are confirmed by the experiments of McNeven and Ducachet. "In the presence of Dr. Francis," says Dr. Ducachet, "I gave a cat about half a pint of milk deeply tinged with indigo. In half an hour I killed the animal, and upon dissection found the *lacteals* containing a fluid of a deep blue colour."—*New-York Med. and Phys. Journal*, vol. i., p. 132.—D.

very greatly increased.* The olive-tree has till of late years only been raised in the south of France by cuttings, or wild plants obtained from the woods. It was remarked by an attentive inhabitant of Marseilles that, when produced naturally, it is by means of kernels carried into the woods, and sown there by birds which had swallowed the olives. By the act of digestion, he further observed, these olives are deprived of their natural oil, and the kernels hence become permeable to the moisture of the earth; the dung of the bird at the same time serving for manure, and perhaps the soda which the dung contains, by combining with a portion of the oil that has escaped digestion, still further favouring germination. Following up this fact, a number of turkeys were made by the experimenter to swallow ripe olives; the dung was collected, containing the swallowed kernels; the whole was placed in a stratum of earth, and frequently watered. The kernels thus treated vegetated easily, and a number of young plants were procured. And in order to produce upon olives an effect similar to that experienced from the digestive power of the stomach, a quantity of them were afterward macerated in an alkaline lixivium; they were then sown, and proved highly productive.

Most of the plants found on coral islands, and in various other places, are propagated by the same means of passing through the digestive canal; and it is probable that the seeds of many of them are equally assisted by the same process. And even when they are completely disorganized and digested, the material to which their refuse is converted, and which, combined with the animal secretions that accompany it, is called dung, very powerfully contributes, as every one knows, to render the soil productive. So that, by the wisdom of Providence, animal digestion and vegetable fructification are equally dependant on each other, and are alternately causes and effects.

Considering the comparatively slender texture of the chief digesting organ, and the toughness and solidity of the substances it overcomes, it cannot appear surprising that mankind should, at different times, have run into a variety of mistaken theories in accounting for its mode of action. Empedocles and Hippocrates supposed the food to become softened by a kind of putrefaction. Galen, whose doctrine descended to recent times, and was zealously supported by Grew and Santarelli, ascribed the effect to concoction, produced, like the ripening and softening of fruits beneath a summer sun, by the high temperature of the stomach. Pringle and Macbride advocated the doctrine of fermentation; thus uniting the two

causes of heat and putrefaction assigned by the Greek writers: while Borelli, Keil, and Pitcairn, resolved the entire process into mechanical action, or trituration; thus making the muscular coating of the stomach an enormous millstone, which Dr. Pitcairn was extravagant enough to conceive ground down the food with a pressure equal to a weight of not less than a hundred and seventeen thousand pounds, assisted at the same time in its gigantic labour by an equal pressure derived from the surrounding muscles.

Each of these hypotheses, however, being encumbered with insuperable objections, Boërhaave endeavoured to give them force by interunion, and hence united the mechanical theory of pressure with the chymical theory of concoction; while Haller contended for the process of maceration. Still a something else was wanting, and continued to be so, till Cheselden, in a lucky hour, threw out the hint (for at first it was nothing more than a hint) of a menstruum secreted in some part of the digestive system; a hint which was soon eagerly laid hold of, and successfully followed up, by Haller, Reaumur, Spallanzani, and other celebrated physiologists. Although Cheselden was mistaken in the peculiar fluid to which he ascribed the solvent energy, namely, the saliva, still he led forward to the important fact; and the gastric juice was soon afterward clearly detected, and its power incontrovertibly established.

[The doctrine of digestion by trituration, or mechanical principles, was founded in a great measure upon an imperfect acquaintance with the digestive organs of birds. Although birds are not furnished with teeth, many of them feed upon hard substances, which, if they were unbroken, the gastric juice could not dissolve. Hence they are furnished with a crop, which is a large membranous cavity at the lower end of the gullet, for the reception of the food when it is first swallowed, and where it is softened by the secreted fluids of the part. They are also provided with a gizzard, into which the food, after being macerated in the crop, is transmitted. The gizzard is a cavity of a moderate size, and flattish, spherical form, composed of four strong muscles. Two of these, which constitute the greatest part of its bulk, are of a hemispherical shape, of a dense and firm texture, and lined with a thick callous membrane. The effect of their action is, to move them laterally and obliquely upon each other, so that whatever is placed between them is subjected to a very powerful combination of friction and pressure. The force is such, indeed, as not only to break down the hardest grains and reduce them to a complete pulp, but even to grind to powder pieces of glass, and to act upon silicious pebbles and masses of metal; while the cuticular lining is so tough as not to be injured by the presence of lancets or other sharp instruments, which have been introduced into the cavity by accident, or for the sake of experiment. However, the action, both of the crop and the gizzard, must be considered as essentially mechanical, the latter being equivalent to the teeth, and the

* In many birds, the pylorus is close to the orifice of the stomach, and has no valve, so that the seeds of plants which have been swallowed readily pass into the intestinal canal. This arrangement must have an important effect in promoting their diffusion. Their disposition to vegetate more quickly after having thus pervaded the alimentary tube, is a fact that was particularly noticed by the late Sir Joseph Banks.—Ed.

former serving merely for the purpose of maceration. A strict connexion is always remarked between the food of birds and the nature of their stomachs; those alone possessing the gizzard which swallow substances that the gastric juice could not dissolve in the entire state. Many writers, in describing the muscular stomachs of granivorous birds, speak of the gizzard as analogous to the digesting stomach of man or of non-ruminant quadrupeds, whereas it is only a substitute for the organs of mastication.* Spallanzani proved, however, that the triturated substance in the gizzard is acted upon by the gastric juice, which is furnished by a glandular apparatus,—the *bulbus glandulosus*, situated at the lower end of the gullet; the structure of the gizzard being evidently not adapted to its secretion. In birds, therefore, digestion is produced by a powerful solvent, just as it is in the human subject.]

The gastric juice, this wonderful menstruum, the most active we are acquainted with in nature, is secreted, as I have already observed, by the capillary arteries that infinitesimally intersect the cellular texture of the stomach, and decussate each other in their ramifications. The quantity secreted during digestion is considerable: Leuret and Lassaigne found that when the gullet of a horse was tied, so as to prevent the secretions of the mouth and gullet from entering the stomach, a full meal of oats became completely saturated with gastric juice in four or five hours. Mr. Cruickshank supposes the quantity of the fluid thus secreted to be about a pound in every twenty-four hours. Yet the quantity seems to vary considerably, according to the demand of the system, or the state of the stomach itself. In carnivorous birds, whose stomachs are called membranous from having little muscularity, and, consequently, whose food is turned into chyme principally by the action of the gastric juice, without any collateral assistance or previous mastication, this fluid is secreted in a much larger abundance; as it is also in those who labour under that morbid state of the stomach which is called canine appetite, and will be distinguished in the present classification by the name of *limosis avens*; as likewise when, on recovery from a fever, or after long abstinence, the system is reduced to a state of great exhaustion, and a keen sense of hunger induces a desire to devour food voraciously and almost perpetually.

[If the contents of the stomach be examined after a long fast, and without any stimulus being applied to its villous membrane, the fluid found in it is a clear, ropy, rather opaque liquid, nearly or quite destitute of acidity. But if any stimulus, even of the simplest kind, be applied to the inside of the stomach, then the fluid secreted is uniformly acid. Hence, during digestion, it is found to be distinctly acid; indeed, free muriatic acid was detected during this process by

Dr. Prout in the stomach of the rabbit, hare, horse, calf, and dog (*Phil. Trans.*, 1824); and also in the matter ejected from the stomach of persons labouring under indigestion. Tiedemann and Gmelin obtained the purest gastric juice by making animals swallow quartz pebbles after a long fast, and killing them an hour afterward. It was generally grayish-white, ropy, and decidedly acid. When taken from the dog and the horse, it contained some mucous, osmazome, and salivary matter, alkaline sulphates and hydrochlorates, the alkali being chiefly soda, besides phosphate and muriate of lime, with other salts in minute proportion; and the acidity was owing to the hydrochloric and acetic acids in the dog, and to these conjoined with the butyric acid in the horse. As the lactic acid of Leuret and Lassaigne is now acknowledged by Berzelius to be a variety of the acetic, all parties may be regarded as agreeing about the presence of that acid in the gastric juice. The researches of Prout, Children, and Graves, confirmed as they have been so amply by Tiedemann and Gmelin, also fully establish the presence of free muriatic acid. When the secretion of the gastric juice is elicited by its natural stimulus, food of various kinds, the chymous mass is invariably acid; and Tiedemann and Gmelin further maintain, as the result of their experiments, that its acidity is greatest when the food is most difficult of digestion. In dogs and cats, the greatest acidity was remarked when they were fed with coagulated albumen, fibrin, bones, or gristle; it was less when they took starch, gelatin, potatoes, or rice; and when they were fed with liquid albumen, the alkaline quality of the food was nearly sufficient to neutralize the acidity of the gastric juice.]

This singular secretion has the peculiar property of coagulating milk, as well as all albuminous substances, which it also as completely dissolves; and hence the milk thrown up from the stomach of an infant, shortly after it has been swallowed, is always found in a curdled state. [By infusing six or seven grains of the inner coat of the stomach in water, a liquor is produced, which, according to Dr. Fordyce, will coagulate 100 ounces of milk; or, according to Dr. Young of Edinburgh, 6857 times its weight of milk.] But the two grand and characteristic properties of the gastric juice are, its astonishing power of counteracting and correcting putrefaction, and of dissolving the toughest and most rigid substances in nature.

Of its antiseptic power, abundant proofs may be adduced from every class of animals. Among mankind, and especially in civilized life, the food is usually eaten in a state of sweetness and freshness; but fashion and the luxurious desire of having it subacted and mellowed to our hands, tempt us to keep several kinds, as game and venison for example, as long as we can endure the smell. The wandering hordes of gipsies, however, and the inhabitants of various savage countries, and especially those about the mouth of the Orange river in Africa, carry this sort of luxury to a much higher pitch; for they seem to regard a feto as a perfume,

* In fact, in that kind of grasshopper termed *acrida aptera*, the heart-shaped gizzard has six longitudinal rows of large teeth, and six intermediate double rows of smaller teeth, making in all 270 teeth.—D.

and value their food in proportion as it approaches putrefaction.

Now, all these foods, whatever be the degree of their putridity, are equally restored to a state of sweetness by the action of the gastric juice, a short time after they have been introduced into the stomach. Dr. Fordyce made a variety of experiments in reference to this subject upon the dog, and found in every instance, that the most putrid meat it could be made to swallow was in a very short period deprived of its putrescency. We cannot, therefore, be surprised that crows, vultures, and hyenas, which find a pleasure in tainted flesh, should fatten upon so impure a diet; nor that the dunghill should have its courtiers, among insects, as well as the flower-garden.

The gastric juice has hence been employed as an antiseptic in a variety of cases out of the body. Spallanzani ascertained that the gastric juice of the crow and the dog will preserve veal and mutton perfectly sweet, and without loss of weight, thirty-seven days in winter; while the same meats, immersed in water, emit a fetid smell as early as the seventh day, and by the thirtieth are resolved into a state of most offensive putridity.

Physicians and surgeons have, in like manner, availed themselves of this corrective quality; and occasionally employed the gastric juice of various animals internally, in cases of indigestion from a debilitated stomach; and externally, as a check to gangrene, and a stimulus to indolent ulcers.

Yet, the gastric juice is as remarkable for its solvent, as for its antiputrescent property. Of this any industrious observer may satisfy himself by attending to the economy of digestion in many of our most common animals. But it has been strikingly exemplified in the experiments of Reaumur, Spallanzani, and Stevens.* Pieces of the toughest meats, and of the hardest bones, enclosed in small perforated tin cases, to guard against all muscular action, were repeatedly, by the two former of these physiologists, thrust into the stomach of a buzzard. The meats were uniformly found diminished to three fourths of their bulk in the space of twenty-four hours, and reduced to slender threads; and the bones were wholly digested either upon the first trial, or a few repetitions of it. The gastric juice of a dog dissolves ivory and the enamel of the teeth; that of a hen has been found to dissolve an onyx, and diminish a louis-d'or. And it is not many years ago, that the handles of several claspknives were found half-digested, and the blades blunted, in the stomach and intestines of a man, who had some time before swallowed these substances out of hardihood, and at last died in one of the hospitals of this metropolis. [The experiments of Leuret, Lassaigne, Tiedemann, and Gmelin, all confirm the statements of Spal-

lanzani, Stevens, Gosse, and others, and contradict those of Montègre, who supposed that the gastric juice did not act out of the body. Leuret and Lassaigne remarked, that the fluid procured by long sponges from the stomach of a duck while fasting, when kept upon bread crumbs, at a temperature of 88 degrees Fahrenheit, soon divided them into minute particles, and formed with them a homogeneous mass, precisely like chyme; and that, when flesh was mixed with the gastric juice of a dog, it was quickly softened and deprived of weight. The observations of Tiedemann and Gmelin are more particular. The fluid found in the stomach of a dog, during the digestion of bones and coagulated albumen, was made the subject of experiment, and comparative observations were made with water and with milk. Various kinds of food were tried, such as bread, coagulated albumen, raw flesh, and boiled flesh; and in every instance it was observed, that the bread was broken down, in the course of eight or ten hours, into a pap, and the surface of the beef and albumen was converted into a pulp, which could be easily scraped off. Montègre is supposed to have failed in procuring similar results, because the fluid with which he operated, was not gastric juice, secreted in consequence of the application of some stimulus to the stomach, but a mixture of saliva, the mucus of the gullet, and the kind of fluid found by Tiedemann and Gmelin in the stomach while empty and not stimulated. Yet Leuret and Lassaigne, it is to be observed, succeeded with the gastric juice of a duck, though the animal was in the fasting state. A convincing proof of the power of the gastric juice to dissolve substances out of the body, as well as of its great antiseptic property, has lately been put upon record. A lad had a fistulous opening leading into the stomach, from which the gastric juice was readily procured, by means of a hollow bougie and elastic bottle. A piece of beef, connected with a thread, was introduced into the stomach, and another piece was put into a vial of gastric juice, the temperature of which was 100°, the same as that within the stomach itself. The piece in the vial underwent a perfect dissolution, though more slowly than that in the stomach, probably in consequence of the latter being continually exposed to fresh gastric juice, and the peristaltic action of the stomach. Solutions of beef and chicken thus procured, remained a whole month in hot weather, free from fetor and sourness.*—(*American Medical Recorder*, January, 1826.) Tiedemann and Gmelin even attempted

* For Dr. Stevens's experiments, which were numerous and well conducted, see his *Dissertatio Physiologica Inauguralis*; or an analysis of it in *Edin. Med. Comment.*, vol. v. p. 146.

* The experiments here alluded to have recently been published in detail by Dr. Beaumont, who, in his curious and instructive work entitled "*Experiments and Observations on the Gastric Juice and the Physiology of Digestion*," has added much valuable information to this portion of physiology. Alexis St. Martin, the subject of experiment, was accidentally wounded in the side by the discharge of a musket, which removed the integuments and muscles of the size of a man's hand. On recovering, a perforation about two and a half inches in

to accomplish, by means of the simple substances contained in the gastric juice, the same solution or digestion that is effected by this secretion itself; and they found that dilute acetic acid, dilute hydrochloric acid, a weak solution of acetate of ammonia, will severally dissolve most animal substances used as food. The experiments, however, were incomplete, because the effect of the foregoing articles, united together as they are in the gastric juice, was not tried.]

It is in consequence of this wonderful power that the stomach is sometimes found in the extraordinary action of digesting its own self; and of exhibiting, when examined in dissection, various erosions in different parts of it, and especially about its great extremity. It was the opinion of Mr. Hunter (*Phil. Trans.* 1772, vol. lxii. p. 447), however, that such a fact can never take place except in cases of sudden death, when the stomach is in full health, and the gastric secretion, now just poured forth, is surrounded by a dead organ. For he argues plausibly, that the moment the stomach begins to be diseased, it ceases to secrete this fluid, at least in a state of perfect activity; and that so long as it is itself alive, it is capable, by its living principle, of counteracting the effect of this

solvent power. Yet it has been found thus eroded, in some cases, where death has followed long constitutional illness. Dr. Wilson Philip has occasionally found similar erosions in the stomachs of rabbits (*Treatise on Indigestion*, &c., p. 62. 8vo. Lond., 1824), and apparently from the cause suspected by Mr. Hunter.*

* On this very curious subject, Andral has not yet made up his mind, and deems further observations necessary.—(*Anat. Pathol.* t. ii. p. 28.) The late Dr. Armstrong also entertained some doubt respecting the correctness of Mr. Hunter's doctrine. "If," says he, "the operation of the gastric juice after death, were the cause of the dissolution of parts of the stomach, this appearance would surely be one of the most frequent in morbid anatomy; whereas it is notoriously very rare." He adds, that, in every instance that he had seen, the most unequivocal signs of disease existed for some time before death.—(*Morbid. Anat. of the Bowels*, p. 46. 4to. Lond., 1828.) On the contrary, Mr. Hunter asserts, that there are few dead bodies, in which the great end of the stomach is not in some degree digested.—(*Phil. Trans.*, vol. lxii.) The examples seen by Dr. Armstrong himself were perforations of the stomach during life. Instead of most frequently occurring in the great, they happened principally in the pyloric extremity of that organ; they were also generally the result of disease, indicated before death by a train of violent and rapidly fatal symptoms. The cases alluded to by Mr. Hunter are totally different, being attended during life with no symptoms of disease of the stomach, and often occurring in persons who have been suddenly killed in the midst of perfect health. In order to explain why digestion of the stomach does not take place in all animals that are killed while in full health, Adams referred to the opinions of Hunter concerning real and apparent death; and was led to conclude, that the digestion only took place when life was so completely and suddenly annihilated, that the blood remained fluid, and the limbs free from stiffness. The facts adverted to by Dr. Carswell, however, sufficiently refute this explanation. Certainly one of the most striking circumstances, in relation to the perforations of the stomach which happen after death, is their usual seat in the great extremity of that organ. It is in this part that fluids accumulate after death by the influence of their own gravity. Mr. Hunter also pointed out another important consideration, which is, that alterations, resembling those of the stomach, are frequently met with in other viscera, to which the contents of that organ directly extend their effects, after its own partial digestion; as the liver, diaphragm, spleen, left lung, and intestines. As my friend Dr. Carswell observes, another equally remarkable fact, is the extension of these alterations in a direction in which a fluid alone could act or be carried, together with the total absence of all redness or other sign of inflammation or adhesion, the formation of pus, &c.—(See *Edinb. Med. and Surgical Journ.*, October, 1830.) This paper contains an account of various interesting experiments, and an examination of all the opinions hitherto delivered on the cause of dissolutions of the stomach met with in the dead subject. The observations of Adams, A. Burns, Spallanzani, Bretonneau (*Archiv. de Méd.* t. xii. p. 345), Carlisle, A. Cooper, and Carswell, fully establish the truth of Hunter's views. As Dr. Carswell has set down acidity of the gastric juice as essential to the production of the effects here treated of, it might be proper, in a repetition of his experiments, to substantiate this remark, by trying whether the

circumference still existed in the stomach. Dr. B. was thus enabled to observe its inner surface, to remove its contents and secretions, to introduce and withdraw at pleasure any articles of food, and to study their changes. The following are some of his conclusions: The inner coat of the stomach is of a pale pink colour, varying in its hues, according as the stomach is full or empty. It has a velvet-like appearance, and in health is always covered with a thin transparent mucus, which differs physically and chymically from the gastric juice. The gastric juice is limpid, colourless, and slightly viscid. It is secreted by vessels distinct from the mucous follicles, and it is never found free in the stomach, unless excited to discharge itself by food or other stimulants. It acts as a solvent of the food, and its action is assisted by the warmth and by the transverse and longitudinal motions of the stomach. It contains, according to the analyses of Professors Silliman, Dunglison, and Emmet, free muriatic acid and some other active chymical principles. By introducing thermometers into the stomach, its natural temperature was found to be 100° Fahrenheit: the temperature was elevated by exercise and depressed by rest.

In the New-York Medical Repository, vol. xii., Dr. Waterhouse has made known the particulars of a case of fistulous opening of the stomach, occurring in a German female who had borne several children; the phenomena marking the action of the gastric juice and the process of digestion, were in many respects similar to those noticed by Dr. Beaumont; and when Dr. Beaumont's communication was read to the French Academy, M. Roux stated that a similar case had occurred in Paris, and that the patient's death was evidently hastened by the experiments tried on her. Professor Jackson, of Philadelphia, however, denies the existence of the gastric juice, and says (*Principles of Medicine*, p. 348), "the presumed gastric juice is then no other than the salivary, buccal, pharyngeal, esophageal, and stomachical follicular secretions and exhalations, collected in the stomach."—D.

VOL. I.—C

Is it upon the principle laid down by Mr. Hunter, that, when the stomach is in a state of disease, it ceases to secrete a gastric juice of full vigour and activity, that we can account for the existence of exotic worms and the larvæ of insects and other animals for a considerable period of time without destruction? Thus Collini gives an example of a *lacerta aquatica*, found alive in the stomach two days after it had been swallowed.—(*Journ. de Méd.*, tom. li. p. 460.) Frogs and serpents have, for a longer period of time, been equally able to resist the action of the stomach; leeches, swallowed unintentionally in a draught of muddy water, have thriven and grown to an enormous size; the eggs and larvæ of various insects, and especially of the *musca cibaria*, and even of the spider, have been hatched or perfected in the stomach or intestines, and the kernels of plum and cherry-stones have germinated there.

Muscular action, however, to a certain extent, seems still requisite as an auxiliary in man, and even considerably more so in many animals, especially in graminivorous and granivorous birds.* I have already stated this as one cause of digestion: but M. Magendie has endeavoured to restore it to a much higher importance than fair and unequivocal experiments justify; for he asserts that, what he calls *artificial digestion*, or that of alimentary substances mixed with the gastric juice, and exposed to the temperature of the stomach, does not succeed in reducing the food to chyme. But this, admitting the fact, would only show us the use of a living principle, and its influence upon every organ, and the operation or function of every organ; and which cannot be imitated out of the body. The assertion, however, is only advanced upon the single authority of M. Montègre, [the failure of whose experiments, as we have already noticed, is imputed by others to the fact, that the fluid with which he operated was not gastric juice, secreted in consequence of the application of some stimulus to the stomach, but a mixture of saliva with the mucus of the gullet, and the fluid found in the stomach while destitute of food, and not stimulated.† In the artificial imitations of the process of digestion, the churning action of the stomach, however, ought certainly to have been taken into consideration, and a substitute for it adopted.

The influence of the par vagum on digestion is an interesting subject, that has excited considerable attention. Mr. Brodie divided these nerves on the cardia, yet the food still contin-

neutralization of the gastric juice with alkalis, would prevent its action on the stomach. To the living subject they are often given very freely, for the express purpose of improving digestion.—Ed.

* See Sir E. Home's articles, *Phil. Trans.*, vol. xcvi. p. 357; xcvi. pp. 93, 139; c. p. 184; cxiii. p. 77.

† In relation to this point, I may again advert to the case of a healthy young man, who had a fistula in the epigastric region, communicating with the stomach, the consequence of a gunshot wound. Dr. Lovell, of the United States, having collected in a vial a certain quantity of the fluid that escaped from the opening, put a bit of meat into it, which dissolved with great readiness.—See *Anat. Pathol.*, t. ii., p. 27.—**Editor.**

ued to be transformed into chyme. M. Magendie took out a portion of a rib, and divided the par vagum on the œsophagus immediately above the diaphragm: still the conversion of the food, both into chyme and chyle, was not interrupted. However, when the same nerves are divided in the neck, and particularly when a portion of them is removed, the formation of chyme is either very imperfect, or even quite prevented. The investigations of Dr. W. Philip, Breschet, and Edwards, prove, that galvanism applied to the stomach, after the division of the par vagum in the neck, restores the digestive process; and hence the doctrine that digestion depends upon galvanic principles. The fact, however, may only prove, that galvanism is a sufficient stimulus to the vessels of the stomach, to enable them to continue for a time the secretion of the gastric juice.

With respect to the power of the nervous system over digestion, a curious fact was demonstrated by the experiments of M. Magendie; namely, that when the brain and a large portion of the cerebellum of a duck is removed, though the instinct of seeking food and even the power of deglutition may be lost, yet, if food be conveyed into the stomach, it will be digested.

If we are to believe some accounts, the cardiac portion of the stomach is the chief seat of digestion; and when a part of the food has there been acted upon in a certain degree, it is conveyed along the large curvature to the pyloric portion, where the process is completed. It seems also now to be established, that the digestive process does not go on equally through the whole mass of the food, but principally where this is in contact with the stomach; that it proceeds gradually from the surface to the centre of the mass, and that, as soon as a portion is reduced to a homogeneous consistence, it is transmitted into the duodenum, without the delay that would result from awaiting a similar change of the whole.*

The food having undergone a sufficient degree of maceration and mastication, or other mechanical process, by which it is reduced to a state of sufficiently minute division, it is acted upon by the gastric juice and the peristaltic contractions of the stomach, and the result is a complete change in its properties, its conversion into chyme; an alteration in every respect analogous to a chymical change. During the process of chymification, heat is occasionally extricated, and not unfrequently gas, composed of carbonic acid, hydrogen, and azote in various proportions, is evolved. Dr. Bostock regards these, however, not as necessary steps in the process, but rather as the consequence of a morbid state of the function.† Previously to Dr. Prout's experiments, the generation of acid in

* Prout, in *Annals of Philos.*, 1819.

† *Physiol.*, vol. ii., p. 491. Dr. Abercrombie also believes, that, in healthy digestion, no gas is generated in the stomach; but that a certain quantity is evolved in the further progress of the alimentary matters through the intestines, especially in the colon.—See *Pathol. and Pract. Researches on Diseases of the Stomach, &c.*, p. 71., ed. ii., S. C.

the stomach used also to be considered in the same point of view.

Chyme is not always of the same quality, its properties depending much upon the nature of the food. According to recent experiments, made on dogs and horses, it appears that liquid albumen forms under the natural process of digestion a homogeneous fluid, in which the albumen remains quite unaltered; and this sort of chyme passes the pylorus more rapidly than any other. Coagulated albumen is much more slowly dissolved, and the fluid produced possesses the properties of coagulated albumen dissolved in acetic acid. Fibrin and vegetable gluten undergo a similar change. Gelatin is converted into a clear brownish fluid, in which neither gelatin nor albumen can be discovered. White cheese forms an opaque dirty white fluid, containing much animal matter, which, however, is neither the case with gelatin nor albumen. Starch is gradually dissolved, and loses its reaction with iodine, being converted into sugar and amidine. The results obtained with compound articles of food, such as milk, beef, bread, and oats, in various states of mixture, were such as the foregoing facts would lead one to anticipate. Bones gave a liquid that contained not only animal matter, but a large quantity of lime. The general result is, that all the animal principles, except liquid albumen, undergo a material change during chymification, which change generally consists in their being made to approach nearer in their nature to albumen.]

So far, therefore, as the organ of the stomach is concerned in the digestive function, we have some insight into the process. But beyond this, that is to say, of the nature of chylification, we have little or no knowledge that can be depended upon.

The aliment having been reduced to chyme in the stomach, is propelled into the duodenum, where it is converted partly into chyle, which is absorbed into the system from the small intestines, and partly into a residual matter, that assumes the nature of feces in the large intestines, and is ultimately rejected from the system. As it is into the duodenum that the biliary and pancreatic ducts discharge their respective fluids, chylification is generally presumed to be essentially connected with the action of the bile and pancreatic liquor.

[The constancy of the liver, not only in all red-blooded animals, but in the intervertebral with colourless blood, wherever a heart and bloodvessels are present, its magnitude, and the destructive and grievous consequences arising from its diseases, are convincing proofs of its high importance in the animal economy. With

these facts, it may seem extraordinary that physiologists should not be in possession of some clear information respecting the functions of this organ, and the uses of the bile. In particular, the action of the latter secretion in chylification is but imperfectly understood. Its ordinary production from venous blood is a peculiarity that does not belong to any other secretion;* while the great difference of its chymical qualities from those of every other fluid in the body, is a point not less remarkable.

One obvious mode of forming a judgment of the uses of the bile, is to remark what ill effects result from the stoppage of its flow into the intestinal canal. On this point, however, the most discordant statements prevail. If we are to credit Dr. G. Fordyce, when the ductus communis choledochus is tied, or blocked up by a calculus, the formation of chyle is not prevented, and consequently the biliary secretion is not essentially necessary for digestion. The same conclusion, with respect to its having no share in the formation of the chyle, is also adopted by some distinguished physiologists of the present time, as will be presently explained. On the other hand, Mr. Brodie, after tying the common biliary duct in young cats, was led to espouse an opinion long ago prevalent, that the principal use of the bile was to separate the chyle from the chyme; for he found, that when that duct was tied, and food given, chymification went on in the stomach as usual; but that no chyle could be detected in the intestines or the lacteals, which only contained a transparent fluid imagined to be lymph, and the watery part of the chyme.—(*Sec Journal of Science and the Arts*, vol. xiv., p. 343.) The same view is also supported by Mr. Mayo's experiments.

Leuret and Lassaigne tied the common duct in a dog, and cleared out the intestines by giving the animal a little castor-oil. Twelve hours after the operation, they thrice gave it bread and milk with sugar, at intervals of six hours; and eight hours after the last meal it was strangled, and immediately opened. The stomach contained an acid pulp, and a very soft, whitish, sweet chyme adhered to the villous coat of the duodenum, and increased its consistence downwards. In the great intestines it was firm, but had the same colour, and was nearly destitute of taste and smell. The thoracic duct was distended with a yellowish red, transparent fluid, which coagulated on exposure to the air, and yielded the usual proportion of fibrin, albumen, and saline matters.

Tiedemann and Gmelin, whose investigations are more elaborate and precise, remarked, that animals were attacked with vomiting soon after

* In some rare instances, the vena portæ, instead of going to the liver, has terminated directly in the lower vena cava; yet bile was secreted, and, of course, from arterial blood.—(Abernethy in Phil. Trans., vol. lxxxi., and Lawrence in Med. Chir. Trans., vol. iv., p. 174.) M. Simon found, that tying the hepatic artery in pigeons did not prevent the secretion of bile; but that a ligature on the vena portæ had this effect. On the other hand, Mr. B. Phillips tied this vein in two dogs, and ob-

served that in both instances bile continued to be secreted, though in small quantity. His experiments on the hepatic artery agree with those of M. Simon. The variety in the distribution of the vena portæ affects several hypotheses respecting the use of the liver, and especially that of M. Magendie, which represents all drink as passing through the branches of this vein, and as undergoing some change in the liver, previously to its entrance into the circulation.—EDITOR.

the operation; then with thirst and aversion to food; and that, on the second or third day, the conjunctiva of the eyes became yellow, the stools chalky and very fetid, and the urine yellow, and convertible to blue, and then red, by nitric acid. Some of the animals died; others were killed. Of the latter, some had previously recovered from the jaundice, owing to the re-establishment of the duct by the effusion of lymph around the tied part, and the subsequent discharge of the ligature; a fact also noticed by Mr. Brodie in his experiments. In the cases in which the biliary duct continued impervious, the colouring matter of the bile was found in the blood, the serous membranes, the cellular tissue, the coats of the arteries and veins, and in the fat. It was further observed, that chymification went on as perfectly as in a sound animal. In the small intestines, they found nearly the same principles as in the healthy state, with the exception of those derived from the bile; and, in particular, they found in the duodenum, and in contact with its membrane, the soft mucous flakes which some physiologists consider, though, as Gmelin and Tiedemann think, erroneously, to be chyle. With the exception of the absence of certain biliary principles, the contents of the great intestines were likewise similar to those met with in the bowels of healthy animals; but they had an exceedingly fetid smell. In such animals as had been fed a little while before death, the thoracic duct and the lacteals always contained an abundant fluid, generally of a yellowish colour. It coagulated, like ordinary chyle; the crassamentum acquired the usual red colour; its difference from the chyle of a sound animal was, that after tying the ductus choledochus, it was never white. The reason of the difference is ascribed to the circumstance of the white colour depending upon fatty matter taken up from the food by means of the bile, which possesses the power of dissolving fat, and probably, therefore, aids in effecting its solution in the chyle at the mouths of the lacteals. It is supposed that Mr. Brodie was deceived by the absence of the white colour, which, it is true, the chyle usually possesses, but which, as it is well known, it does not exhibit unless the food contain fatty matter. Mr. B. Phillips also infers, that chyle may be formed independently of the influence of the biliary secretion, and he not only adverts to examples in which the ductus communis had been rendered impervious, by the pressure of tumours, but gives the particulars of experiments made on four dogs, in which he found chyle in the thoracic duct, after the ductus communis had been tied.

The following are the uses ascribed to the bile by Tiedemann and Gmelin; First, by its stimulant properties, it excites the flow of the intestinal fluids, as is proved by the unusual dryness of the feces in jaundiced persons, and in animals, whose common duct has been tied. Secondly, it probably stimulates the intestinal muscular fibres to action. Thirdly, as it contains an abundance of azotized principles, it may contribute to animalize those articles of food which have no azote in their composition.

Fourthly, it tends to prevent the putrefaction of the food during its course through the intestines; because, when it is prevented from flowing into them, their contents are much further advanced in decay than in the healthy state. Fifthly, it probably tends to liquefy and render soluble the fatty part of the food. Lastly, it is to be regarded as an important excretion.

According to the researches of the same physiologists, many of the principles of the bile, such as its resin, colouring matter, fatty matter, mucus, and salts, are thrown out of the body, with the feces, in the natural state of the biliary system, or by the urine, or into the cellular tissue, when the excretory duct of the liver is obstructed. These principles contain a large proportion of carbon, and would appear, therefore, to be intended to carry off the excess of that element which is introduced into the system with vegetable food, and not thrown off by the lungs. In the lungs, it is thrown off in the state of oxydation; in the liver, chiefly in union with hydrogen, and in the form of resin and fatty matter. That the liver is thus intended to assist the lungs in decarbonizing the blood, seems to Gmelin and Tiedemann confirmed by the following facts: The resin of the bile abounds most in herbivorous animals, whose food contains a large proportion of carbon and hydrogen. In various tribes of animals, the pulmonary and biliary organs are in a state of antagonism to one another; a fact particularly insisted upon by Fourcroy. The size of the liver and the quantity of the bile are not proportionate to the quantity of the food and frequency of eating; but inversely to the size and perfection of the lungs. Thus, in those warm-blooded animals which have capacious lungs, and live always in air, the liver, compared with the body, is proportionately less than in such as live partly in water. The liver is proportionately larger in reptiles, which have lungs with large cells, incapable of rapidly decarbonizing the blood; also in fishes, which decarbonize the blood but slowly by the gills; and, above all, in molluscous animals, which effect the same change very slowly, either by gills, or small, imperfectly developed lungs. Another thing, pointed out as highly deserving notice, is the increased quantity of blood transmitted through the liver, when the pulmonary system becomes less perfect. In mammalia and birds, the vena portæ is formed by the veins of the stomach, intestines, spleen, and pancreas; in the tortoise, it receives also the veins of the hind legs, pelvis, tail, and vena azygos; in serpents, it receives the right renal, and all the intercostal veins; in fishes, the renal veins, and those of the tail and genital organs.

Another observation, made by the same professors, is, that, during the hybernation of certain animals of the class mammalia, when respiration is suspended, and no food is taken, the secretion of bile goes on. An additional argument, in favour of the preceding hypothesis, is deduced from the physiology of the fœtus, in which the liver is proportionately a great deal larger than in the adult, and in which the bile

is secreted abundantly, as appears from the great increase of the meconium during the latter months of pregnancy. Finally, another argument is derived from pathological facts. According to Tiedemann and Gmelin, in pneumonia and phthisis, the secretion of the bile is increased; in diseases of the heart, the liver is enlarged; and, in the morbus caruleus, the liver retains its foetal state of disproportion. In hot climates, where, in the opinion of these physiologists, respiration is less perfectly carried on than in cold ones, owing to the greater rarefaction of the air, a vicarious decarbonization of the blood is established by an increased flow of the bile.

The foregoing hypothesis is, perhaps, better supported than that of Sir Everard Home, who considers one of the offices of the bile to be that of converting mucus, or the refuse matter of the chyle, as it passes along the colon, into fat, which is absorbed into the system. This indefatigable physiologist was partly induced to adopt this opinion by the example which he met with of a child, in which the peristaltic action of the bowels had been duly continued, and stools regularly produced, without any intermixture of bile, and even when no gall-bladder, nor any duct leading from the liver into the duodenum, existed.—(*Phil. Trans.*, 1813, art. 21.) The mere circumstance of this child being in a state of marasmus at its death, without any manifest intestinal disease, however, scarcely warrants the theory attempted to be built upon it, and which may be regarded as the reverse of what is inculcated by Fourcroy, Gmelin, and Tiedemann, who represent the bile as depriving the system of its redundant carbon and hydrogen, and not as a means of supplying a larger quantity of these elements to it.

Besides the secretion of the duodenum itself, which is supposed to be concerned in chylication, the pancreatic juice is another fluid apparently intended for the same purpose. The common opinion has been, that, in its nature, it is very similar to saliva: Tiedemann and Gmelin, however, represent it as differing materially from this fluid, and never containing any sulphocyanic acid, free soda, or mucus; as being naturally acid; having a much larger quantity of solid matter; and especially a greater proportion of albumen; and, in the dog at least, a peculiar principle, soluble in water and in alcohol, and, when pure, precipitated rose-red by chlorine. Sometimes, it contains also a good deal of phosphate and acetate of soda. The pancreatic fluid of the dog, horse, and sheep, when heated, yields a large quantity of coagulum, which the saliva does not. The particular use of the pancreatic secretion in digestion is unknown. Tiedemann and Gmelin, reasoning from the large quantity of azotized principles which it contains, presume, that its use may be to animalize vegetable food. They remark, as a confirmation of this opinion, that the pancreas is much larger in herbivorous, than carnivorous animals.—(See *Edin. Med. and Surg. Journ.*, Nos. 91 and 93.)

Of the action of the omentum and spleen, we

know nothing certain.* The spleen secretes no peculiar fluid; its blood is of a dark livid colour, and coagulates with difficulty. It is even destitute of an excreting duct; and, in some instances, has been extirpated without injury to the general health. It is not found in any tribes below the class of fishes. [To some of the hypotheses concerning the use of the spleen, reference has already been made. The experiments of Leuret and Lassaigne led them to revive the hypothesis, that the spleen is a mere diverticulum for the blood during digestion. When the stomach and intestines are distended with food, and the process of digestion is going on, the blood flows in an increased quantity to the villous membrane of the whole alimentary canal, and consequently more venous blood requires to be returned by the hepatic vessels. These, however, being presumed to be inadequate to the purpose, the splenic veins and cells become gorged. It was found, that the spleen of the dog, which generally weighs but a few ounces, acquired the weight of a pound and a half two hours and a half after a ligature had been applied to the vena portæ. In the dog, cat, rabbit, Guinea pig, and other mammalia, the spleen presented a rosy or vermilion tint while the animals were fasting; after chymification had begun, it assumed a blue colour, and was somewhat tinged; but it did not acquire its deep bluish-black colour, and greatest turgescence, till the chyme had passed the pylorus, when the intestinal membrane participated in the activity previously confined to the stomach. This hypothesis is liable to the objection, that, if true, the absence or removal of the spleen ought always to occasion more serious consequences than it is said to do.

Tiedemann and Gmelin represent the structure of the spleen as essentially resembling that of the lymphatic glands, and regard it as an organ which is merely an appendage to the absorbent system. They believe that its specific function is to secrete from the blood a reddish fluid that has the property of coagulating, is carried to the thoracic duct, and, being there united with the chyle, changes it into blood.

* Dr. James Rush considers the omentum to be "an organ for the secretion of fat, furnished with vesiculæ for its reception, in order to supply the body with nourishment when the resources by the stomach fail." Among other reasons for this opinion, he mentions its structure, situation, its little sensibility, its presence in most animals, its absence in others; its state in the hibernating animals, &c.—(See *Med. and Phil. Reg.*, vol. vi., No. 1, p. 67.) In regard to the spleen, Dr. Rush says (*Med. Museum*, vol. iii., p. 10), "All the motions which go forward in the human body, are produced by external and internal stimuli. These stimuli exert their influence directly and indirectly upon the bloodvessels. From innumerable causes they are liable to become excessive in their force. The provision to defend the tender and vital parts of the body from the effects of this force, I believe to be the spleen." This theory, which is supported by many ingenious arguments, has recently been revived as new, by Dr. Hodgkin.—See *Ed. Med. and Surg. Journ.*, Jan., 1832,—D.

The facts, elucidated by the experiments of these physiologists, are of great value: yet, their hypothesis, relative to the spleen being an organ of sanguification, is seriously shaken by the facts, that a vast difference really exists between the structure of the spleen and that of an absorbent gland; that the chyle does not invariably exhibit a reddish hue; and that the absence or removal of the spleen may happen, not only without fatal effects, but even without much subsequent disturbance of the animal economy.

Notwithstanding the progress of animal chymistry, and the multiplication of experiments on living animals, we are obliged to confess, that our knowledge of the rationale of chylification is still involved in considerable obscurity. But, though we know not the exact way in which this process is effected, our acquaintance with the properties of the chyle itself is more satisfactory. For the most accurate information concerning the chyle, we are indebted to Dupuytren, Vauquelin, Emmert, Marcet, Prout, Tiedemann, and Gmelin. If the animal, from which the chyle is extracted, has eaten animal or vegetable substances of a fatty nature, the liquid, drawn from the thoracic duct, is of a milky appearance, a little heavier than distilled water, of a strong, spermatic odour, of a salt taste, slightly viscid, and plainly alkaline. It soon separates into three parts: a solid one, that remains at the bottom; a liquid one, at the top; and a third, which forms a very thin layer on the surface. At the same time, the chyle assumes a bright rose colour. When, however, it is derived from food void of fat, it is opaline, and nearly transparent, instead of being of an opaque white colour, and the layer on the surface is less evident. Chyle never takes the hue of colouring substances in the food. M. Hallé proved this by direct experiments. Magendie also made animals eat indigo, saffron, and madder, without the colour of these articles being communicated to the chyle. This fact, which is confirmed by the experiments of Tiedemann and Gmelin in Germany, Andrews at Edinburgh, and Lawrence and Coates in America, is very important, because it is at variance with Mr. Hunter's statement, and upon its correctness the truth of the theory, which restricts the function of the lacteals entirely to the absorption of chyle, and of no other matter, mainly depends. Chyle, derived from sugar, contains hardly any fibrin; while that from flesh has a great deal. The appearances and quality of this fluid are, therefore, considerably modified by the kind of food; and it deserves particular recollection, that, as it is not always white, its pink or transparent look is not to be regarded as a proof,

either of the lacteals having imbibed madder, or of the imperfect formation of the chyle.] M. Magendie's experiments led him to conclude, that a dog, upon an average, forms about six ounces of chyle every hour. The subject is highly interesting: but to pursue it further, and especially into that diversity of structure which the digestive organs present in almost all the different classes and orders, adapted, as it is in each of them, with the most skilful attention, to the general economy of their nature, and the mode of life they are destined to lead, would occupy more space than we can spare, and carry us into the regions of general physiology. Enough has perhaps been said, and this is all that has been aimed at, to give a compendious view of the organs which form the seat of that class of idiopathic diseases, with which the nosological system about to be unfolded commences, and consequently to enable the reader to follow up those diseases with greater clearness and comprehension in their distinctive characters and descriptions.*

I have limited the above remark to *idiopathic* diseases; and it is necessary the limitation should be attended to. For, from the intimate connexion which the organs of digestion maintain with other organs and sets of organs, there are few general complaints in which the first do not evince some *sympathetic* affection. This is particularly the case with the stomach, which, in the opinion of Mr. Hunter, is the seat and centre of universal sympathy; a doctrine which appears to have been taught in France by M. de Bourdeu,† though with less caution, and from fewer premises, at the very time Mr. Hunter was teaching it in London.

The sympathetic affections here spoken of, cannot fall within the range of the present class; but must necessarily appertain to those diseases and divisions of diseases, under which they rank as peculiar symptoms, and which can only be removed by removing the idiopathic malady.

* Dr. Abercrombie sums up, in a few words, the principal circumstances necessary for the healthy condition of the process of digestion: 1. A healthy state of the muscular action of the stomach; 2. A healthy, consecutive, and harmonious action of the muscular coat of the intestinal canal; 3. A healthy state of the fluids of the stomach; 4. A healthy state as to the quantity and quality of other fluids, derived from the liver, pancreas, and mucous membrane of the intestines; 5. A healthy state of the mucous membrane itself, both in the stomach and the intestines.—See *Abercrombie's Pathol. and Pract. Researches on Diseases of the Stomach, &c.*, p. 71, ed. 2. S. C.

† See his Thesis, "An Omnes Corporis Partes Digestioni opitulatur?" Paris, 1754.

CLASS I.

CŒLIACA.

ORDER I. ENTERICA.

DISEASES AFFECTING THE ALIMENTARY CANAL.

DISQUIET OR DISEASED ACTION IN SOME PART OF THE PASSAGE FOR THE RECEPTION AND DETRICTION OF FOOD.

THE diseases of the DIGESTIVE FUNCTION form the first class in the Nosological System about to be unfolded; and to these, from the Greek term ΚΟΙΛΙΑ, "alvus," "venter," or "the lower belly," I have applied the classic name of CŒLIACA.

By an easy and natural arrangement, this class is divisible into two orders; the first embracing those disorders which affect the alimentary canal; and the second, those which affect the collatitious or auxiliary viscera. The former I have distinguished by the term ENTERICA, and the latter by the term SPLANCHNICA, both of which are Greek adjectives; the one being a derivation from ἔντερον, "intestinum," "alvus;" and the other from σπλάγχνον, "viscus," "a bowel, or entrail."

The present order embraces the following genera:—

I. Odontia.	Misdentition.
II. Ptyalismus.	Ptyalism.
III. Dysphagia.	Dysphagia.
IV. Dipsois.	Morbid Thirst.
V. Limosis.	Morbid Appetite.
VI. Colica.	Colic.
VII. Coprostasis.	Costiveness.
VIII. Diarrhœa.	Looseness.
IX. Cholera.	Cholera.
X. Enterolithus.	Intestinal Concretions.
XI. Helminthia.	Worms.
XII. Proctica.	Proctica.

GENUS I. ODONTIA. MISDENTITION.

PAIN, OR DERANGEMENT OF THE TEETH, OR THEIR INVOLUCRES.

THIS genus has by some writers been called odontalgia and odaxismus. But as both these terms have been limited by other writers to a single species of the genus, that of odontia *dolorosa*, or toothache, in order to prevent confusion, I have ventured to give it the name under which it now appears; derived from ὀδὺς, "a tooth," which in fact is the common root of all the terms, and is here preserved in its simplest form.

The involucre of the teeth are their gums, membranes, and sockets, or alveoli. The last, although an immediate apophysis of the jaw-bones, are rather to be regarded as an apper-

tenance of the teeth, than of the bones from which they issue. They are altogether limited to the duration of the teeth, sprouting forth at their commencement, and being carried away by absorption, on their decay or removal. They are also in every instance modelled by the shape of the teeth; and, like the gums, participate in almost all their diseases.

The character of the present genus is therefore made sufficiently general to embrace the disorders of these adjuncts of the teeth, as well as of the teeth themselves: all which, as distinct species, may be conveniently arranged in the following order:—

1. Odontia Dentitionis. Teething.
2. ——— Dolorosa. Toothache.
3. ——— Stuporis. Tooth-edge.
4. ——— Deformis. Deformity of the Teeth.
5. ——— Edentula. Toothlessness.
6. ——— Incrustans. Tartar of the Teeth.
7. ——— Excrescens. Excrescent Gums.

SPECIES I ODONTIA DENTITIONIS. TEETHING.

IRRITATION FROM CUTTING THE TEETH.

DR. CULLEN did not allow dentition to enter into the list of diseases; but this is to suppose the process of teething to take place at all times, instead of only occasionally, with perfect ease, and without irritation of any kind. Whenever it occurs in this manner, there is undoubtedly no disease, and so far Dr. Cullen is correct. But in a very large number of cases, perhaps, in refined and intenerated society, in the larger number, there is not only disease, but in many instances disease of an alarming and fatal character, strikingly severe in its progress and complicated in its symptoms. The organism of the *teeth*, indeed, is peculiarly distinguished by the following feature: that there is no other part of the human structure so brief in its duration, and none, with the exception of the uterus, so signalized by pain and inconvenience during its progress. Yet their mechanism, notwithstanding these evils, is most admirable. No effort of human wit has ever been able to improve upon it, even in imagination, and no organ is more strikingly impressed with marks of supernal goodness and intelligence. [The human teeth differ from those of animals, in being all of one length, and having no considerable interspaces between them. Another of their peculiarities is the perpendicular direction of the lower incisors. In animals, these teeth slant backwards, and the jaw also slopes backwards directly from the alveoli, so that the full, prominent chin, is found only in man, while in animals it seems as if it were cut off. In

man, the obtuse tubercles of the grinders are very particular, not resembling the flat crowns with rising ridges of intermixed enamel, belonging to herbivorous animals, nor the cutting and tearing grinders of carnivorous ones.]

There are three periods of life in which dentition, or the breeding and cutting of teeth, uniformly takes place—in infancy, in boyhood, and adult age. Besides which, we meet with instances occasionally of a reproduction of teeth in advanced life. Each of these formations is accompanied with circumstances peculiar to itself; and when attended with pain or morbid action of any kind, affords a distinct modification of the present species of disease, and consequently lays a foundation for the four following varieties:—

- | | |
|-----------------------|---|
| a Lactentium. | Cutting the milk or shedding teeth. |
| Milk teething. | |
| β Puerilis. | Cutting the second set, or permanent teeth. |
| γ Adultorum. | Cutting the adult or wise teeth. |
| Adult teething. | |
| δ Senilium. | Cutting teeth in advanced life or old age. |
| Climacteric teething. | |

Before we enter upon the symptoms of these varieties, it is necessary to give some explanation of the causes which produce them; or, in other words, to take a brief glance at the order and economy of dentition.

As the jawbones of youth are both wider and longer than those of infancy, it is obvious that the teeth which are cut in the first year, must be incapable of filling up the bony arch of the fourteenth. They might, indeed, have been so contrived as to grow in proportion to the increased range of the jawbones; but from their being extraneous bodies, this must have been a complex process, while the very circumstance of their growth, and the internal change which must have continually taken place, would have exposed them to many more diseases than they are subject to at present.

A much simpler plan has been devised; and the teeth of man, as indeed of most mammalia, are composed of two distinct sets, differing both in number and structure: the first, or smaller set, consisting of ten for each jaw, which are cut between the [sixth and twenty-fourth month after birth; the most common period of their first appearance, however, being the commencement of the seventh,*] shed between the seventh and fourteenth year, and from the period of their protrusion called milk-teeth; and the second, or larger set, consisting of fourteen, fif-

teen, or sixteen for each jaw, for they occasionally vary in number, which are cut progressively, upon the shedding of the first set, between the seventh or eighth, and the seventeenth or eighteenth year; and which, from their continuing till old age, except in cases of accident or disease, are denominated permanent teeth. The farthest grinder on each side, however, is seldom cut so early as the eighteenth year, generally after the twentieth, and sometimes not till the thirtieth; on which account, these teeth are denominated *dentes sapientie*, or teeth of wisdom.

Although, in the human subject, the teeth are of no use until a certain time after birth, preparations for their formation commence in the early stages of fetal life. Then the rudiments of all the first set, and of four belonging to each jaw of the second set, are produced, and may be distinctly seen when the fœtus is about four months old: M. Serres declares that he has traced them, and even the teeth, at three.* [The jaw of a new-born child contains a number of cells, separated from each other by imperfect bony septa. By removing the external or internal plate of the jaw, the contents of these cells are exposed. They consist of membranous bags, named the *capsules* of the teeth, enclosing the rudiments of the bodies of these organs, and certain soft vascular substances, termed the *pulps*, on which the bodies of the teeth are forming. The bone of the body of the tooth is the part first formed; the enamel is added to this; and the fang appears the last in order. The pulp, which, according to Meckel, grows up from the bottom of the capsule, about the fourth month of fetal existence, accurately resembles in shape the body of the tooth which is to be formed on it. It is a soft, vascular substance, and its vessels are most numerous in that part which is covered by the portion of tooth already formed. The capsule is a whitish membrane, but very vascular on its inner surface. It includes the pulp, round the basis of which it adheres, and the rudiments of the imperfect tooth. On its outer surface it adheres firmly to the gum; so that, if we attempt to tear the last mentioned part away from the jaw of a fœtus, the capsules and their contents will come away at the same time. These membranes adhere less closely to the bony cells in which they are contained. The office of the capsule is that of secreting the enamel: in its cavity is a small quantity of fluid. The ossification commences by the formation of the cutting edge of the incisors, and the grinding basis of the molares. The bony substance being deposited on the pulp, as on a mould, the rudiments of the teeth are necessarily hollow; and the bony layers first formed, are those which will be in contact with the enamel when it is deposited. As the formation of the tooth advances, the pulp

* Meckel's Anatomy, trans. by Doane, vol. iii., p. 237. A tooth, considered in the most general view, is essentially composed of two parts: one of these, which is constant and always the same, is the secreting part (the soft portion or pulp); the other, which is more or less developed according to the nature of the animal, and varies in shape, disposition, and number of its layers, is the secreted part; the hard portion placed on the edges of the jaws, and sometimes on the vault of the palate, or at other points of the cavity of the mouth.—See Andral, *Anat. Pathol.*, t. ii., p. 259.

* *Essai sur l'Anatomie et Physiologie des Dents*, p. 3. 8vo. Paris, 1817. Andral states, that their rudiments may be detected in the 10th week, as their pulpy portion is then in the jaw; and that, at three months, it is covered with osseous points.—*Anat. Pathol.*, t. ii., p. 259.—EDITOR.

is gradually surrounded, till the whole is covered by bone, except its base.

The adhesion of the pulp to the newly-formed tooth or bone is very slight, and no vessels can be discerned going from one to the other: it is, however, most strongly attached round the thin elastic edge, which is the last part formed. When the bone has covered all the pulp, it begins to contract a little, and becomes somewhat rounded, making that part of the tooth which is called the *neck*, and from this place the *fangs* begin. The formation of the fangs makes the bodies of the teeth ascend through the sockets, and afterward through the gum, which is absorbed in consequence of the pressure of the tooth.

The pulp has originally no process answering to the fang; but, as the cavity in the body of the tooth is filled up by the ossification, the pulp is lengthened, and the fang forms over it. The latter part grows in length till the whole body of the tooth is pushed through the gum, the socket at the same time contracts at its bottom, and grasps the neck or beginning fang, adheres to it, and rises with it. Thus the alveolus is raised with the fang, and the fang does not itself sink or descend into the jaw.

If two or more fangs are to be formed, the process is rather more complicated. When the body of a molaris is completed, there is but one general cavity in the tooth, from the brim of which the ossification is to shoot, so as to form two or three fangs; if two only, then the opposite parts of the margin of the cavity shoot across where the pulp adheres to the jaw, meet in the middle, and thereby divide the mouth of the cavity into two openings, from the edges of which the two fangs grow. It is a curious circumstance, however, that at the very time when the pulp is restricted to the crown of the tooth, the number of future fangs is already denoted by that of distinct branches given off by the dental vessels.—(*Meckel's Anatomy*, vol. iii., p. 232.) When the surface of the tooth first appears through the gum, its body is yet more hollow than that of a perfect tooth, and the fang is only in an incipient state. In proportion as the tooth rises through the gum, however, the aollow is gradually filled up, and the fang is lengthened. When the bone of the body of the tooth is somewhat advanced in its formation, the enamel begins to be deposited on its surface from the vessels of the capsule. This deposition commences on the masticating surface of the tooth, and thence extends towards the root. The enamel is complete when the fang of the tooth begins to be produced, for at that time the body penetrates the gum, and thereby lays open the capsule, which at this period is found to have undergone great alteration in its texture and appearance. Instead of the soft vascular surface which it exhibited while the deposition of the enamel was going on, it is now dense, and almost tendinous, with very few bloodvessels. When the fang begins to grow, the capsule also becomes connected to it, and forms its periosteum.]

From what has been said, it appears that the

alveolus, or socket shoots up from the jawbone as the tooth advances. It accompanies its growth, and at first entirely surrounds it; by which admirable contrivance a firm support is given to the gums from the time of birth, and the infant is enabled to make a sufficient pressure for the purpose of sucking, without interfering with the form which the teeth, yet soft and amorphous, are destined gradually to assume. In due time, however, the alveolus yields in its upper surface, as the tooth, in consequence of the gradual elongation of its fang or fangs, is forced through, and cuts not only the socket but the gum; and when the first set, having answered its temporary purpose, loses its fangs by absorption, and the body of each tooth is shed or cast out by the gums, the attendant sockets are equally absorbed, and disappear at the same time.

This wonderful change begins to take place, as I have already observed, about the seventh year, the artery of the milk teeth and its canal undergoing a more or less perfect obliteration (*Serres*, p. 19); at which time we possess far more teeth, including both the grown and the growing, than at any other period whatever: for we have in each jaw ten temporary teeth complete, ten incomplete to succeed them, and the two permanent grinders, whose stamina were formed during fetal life, making not less than forty-four in the whole. Other writers than Mr. Hunter place this change at an earlier period: Dr. Blake, indeed, as early as the fourth year; and M. Lemaire, who follows Blake in most other points, follows him in this also. The permanent teeth have separate sockets of their own; and, in consequence of the prolongation of the jawbones, do not lie immediately under the corresponding shedding teeth, nor directly contribute to the process of shedding, which chiefly takes place in consequence of the absorption of the fangs and sockets of the temporary set, though their ascent contributes in some degree to the general process.

I have observed that the alveoli, or sockets, though fixed upon the jawbones, and indeed issuing from them, are rather to be regarded as appendages of the teeth than of the bones from which they spring; that they participate in most of the diseases of the teeth, and are strictly coeval with them; sprouting forth on their origin, modelled by their shape, and disappearing on their decay or removal. It is this disappearance, which is the work of absorption, that principally produces that change in the character of the face which peculiarly distinguishes the period of old age. It follows closely upon the loss of all the teeth; and when these have uniformly given way, and their respective sockets are no longer in existence, as not being wanted, the upper jaw becomes considerably diminished in its range, the under jaw reduced to a thin bone merely covered by the gums, and the roof of the mouth, instead of being arched, is rendered almost flat. And from this loss of substance, which is nearly equal to an inch and a half in depth, the face becomes shortened, the cheeks wrinkled, and the chin projecting.

It is curious to observe how differently the teeth are situated in different animals. In the more perfect, they are placed in sockets in the jawbones, some of which are in many kinds rendered moveable, as the two fore teeth of the lower jaw of the *mus maritimus*, or African rat, the largest species of the genus hitherto discovered. The same teeth are equally moveable in the kangaroo; and the hollow tusks or poisoning fangs of the rattlesnake, and other venomous serpents, are capable of depression or elevation at the option of the animal. In the lamprey and myxine the teeth, which are almost innumerable, are placed on the surface of the tongue; in the cancer genus, in the stomach; where we likewise find them in the common earwig. In the cuttle-fish, they are also placed in the middle or lower part of the body, two in number, and horny, and in their figure resembling the bill of a parrot. In the echinus, or sea-hedgehog, they are five in number, arranged around the opening of the under part of the shell, and, being moveable by different muscles, they form a very complete organ of mastication. In the *aphrodita aculeata*, or sea-mouse, they are fixed upon the proboscis, four in number, and are consequently extended or retracted with this organ at pleasure. The leech has three pointed cartilaginous teeth, which it is able to employ in the same way, and by means of which it draws blood freely.*

The form of the teeth is so different, even in the different genera of animals that possess them in a true or perfect state, that this diversity has been laid hold of by many naturalists, as a distinguishing characteristic of their kinds or orders. Linnæus, confining himself to the fore teeth, has hereby formed seven distinct orders for the class of mammalia; and M. de Blainville, carrying the basis of this distinction farther than to the form and structure of the fore teeth, has made it a foundation for the subdivisions of these orders into genera.†

Whatever be the time in which teeth are generated and protruded, the process is often so gradual that little or no pain or other inconvenience is experienced; and, consequently, under such circumstances, there is no disease. But I have already observed, that there is often not only pain and irritation, and therefore disease, but, in various instances, disease of a severe, complicated, and alarming character. And it is to *denition* under these circumstances, that I am now about to direct the reader's attention.

It will readily be supposed, that the most violent symptoms of denition are those produced under the first stage referred to in the preceding history, or during the growth and protrusion of the MILK or SHEDDING TEETH; for the system is then in its tenderest state of infancy, and prone to disorder from very slight causes of irritation.

The immediate cause of irritation in the

present instance, is the pressure of the teeth in the gums; and the degree of irritation depends upon the peculiar temperament of the child. [But, in addition to this circumstance, it may be stated as a general fact, that, the greater the number of teeth coming forward simultaneously, the greater the risk of indisposition; and every man of experience knows that those children which cut their teeth late, usually suffer least.] As the teeth push forward, the superincumbent gum wastes in consequence of absorption, and is at last cut through, and the tooth makes its appearance. This pressure is not, however, uniformly exerted through the whole course of teething, but is divided into distinct periods or stages; as though the vital or instinctive principle, which is what we mean by nature, becomes exhausted by a certain extent of action, and then requires rest and a state of intermission. The first active stage of teething is usually about the third or fourth month of infancy; and constitutes what is called breeding the teeth, or the production of their bone from the pulpy rudiment, buried in the gum, and formed during fetal life, which at the same time shoots downwards, and gives to every tooth a neck and fang. The first and most usual symptom of this change, is the looseness with which the infant grasps the nipple, and the frequency with which it lets go its hold, accompanied with fretfulness and crying, and succeeded by a copious discharge of saliva, the salivary glands partaking of the irritation of the gums. Next, the uneasiness of the gums is found to be relieved by the pressure of any hard substance upon them which benumbs their excited sensibility; and hence the child is pleased with having its gums rubbed with the fingers, a coral, or a gold ring.

This last is perhaps the oldest method, and it may be the best: for the experiments of Dr. Chrestien, of Montpellier, who has of late endeavoured to revive the old preparations of gold as a part of the materia medica, show sufficiently that this metal, in very slight quantities of some of its simplest forms, is peculiarly active, and a powerful exciter of those secretions which have a tendency to diminish irritation and subdue inflammatory action. He has proved before a committee of the Royal Academy of Sciences at Paris, that friction of the tongue and gums with not more than four grains of powder of gold, produces sometimes a copious pytalism, sometimes abundant alvine evacuations, and sometimes profuse perspiration.* Friction by the finger, or any other means, is sometimes condemned, as likely to render the gum callous, and consequently more difficult to be cut through; but, so far as I have observed, this idea is not supported by facts. In many respects, M. Lallemand has since confirmed Dr. Chrestien's observations.†

* Recherches et Obs. sur les Effets des Préparations d'Or. 8vo. Paris.

† Journ. Générale des Sciences Médicales, Août, 1822. Rousseau, in his *Emilius*, objects to rubbing the gums with hard substances, and refers to the instinct of other animals, which leads them to exercise their budding teeth, not on bones or stones,

* See, for other peculiarities, Phil. Trans., vol. lxxxix., p. 237.; xci., p. 319.

† Nouveau Dict. d'Hist. Naturelle, vol. ix., art. DENTS. Paris, 1817.

If the irritation become very considerable, the gums swell, the child grows still more fretful, and starts in its sleep; or, on awaking suddenly, there is heat, thirst, and other concomitants of pyrexia, with perhaps dulness or drowsiness; the bowels are affected, which is a common symptom, and a rash appears on the skin, usually the *red-gum*; and if the irritation extend to the muscles of the chest, there is a dry and troublesome cough. It is the opinion of Dr. Withers, as given in his treatise on asthma, that a cough during dentition never takes place but from primary affection of the respiratory organs: yet I have often seen this effect produced as evidently from mere sympathy, as increased flow of saliva, or looseness of the bowels. In about ten days or a fortnight, these symptoms subside; and though the infant may occasionally be teased with slight paroxysms of uneasiness, it generally passes on without much inconvenience till the arrival of the second stage, or period of cutting the teeth, which we may expect to take place between the seventh and the close of the ninth month, though sometimes this does not occur till a few months later.

This is the usual progress; but here, as in many other organs of the system, we sometimes meet with a singular precocity of action, and, at other times, with as extraordinary a hebetude: and hence, while it is 'no uncommon thing for an infant to be born with several of its milk-teeth already cut, a fact which has in various instances occurred to my own observation, and is specially noticed by Helwig* and other writers; sometimes these teeth are extremely tardy in their appearance, and, in one instance, are said not to have been protruded before the child was ten years old.† [M. Dugès saw an example in which no teeth were cut till the age of eleven; and Smellie refers to instances of much greater retardation, where persons were twenty-one or twenty-two years old when their teeth first appeared. The appearance of teeth at birth is sometimes alleged to be particularly

but softer substances. In accordance with this view, a stick of marsh mallows, or of liquorice root, a piece of wax candle, or a crust of bread, has been recommended instead of coral; and in France, they often dip the substance in honey, or a sweet decoction of barley. In some parts of Germany, children are frequently seen sucking a small bag, containing a mixture of sugar and spices, which is given to them whenever they are fretful. By keeping them quiet, the nurse is saved trouble; but the derangement of the stomach likely to arise from so free a use of these sweet stimulating ingredients, must be objectionable.—See DENTITION, in the Cyclop. of Pract. Med., p. 518.—Ed.

* Obs. 28. Richard III., Louis XIV., and Mirabeau, seem to have been born with some of their teeth already cut; but the circumstance is common enough in all ranks of society.—Ed.

† Eph. Nat. Cur. Dec. 11. Ann. iv. Obs. 28. In all probability these were really the permanent teeth, and not the milk ones, as mentioned in the text. In such cases, Andral concludes, that the failure of the first dentition must be owing either to the non-existence of the germs, or else to the pulp, though developed as usual, not secreting the hard portion.—Anat. Pathol., t. ii., p. 260.—Ed.

frequent in infants born after the usual period (*Meckel's Anat.*, vol. iii., p. 242); but such premature dentition is neither a proof of protracted pregnancy, nor yet of, what is also stated, a strong constitution in the infant, which is often unusually small, and does not thrive. We have, indeed, high authority* for the observation, that perfectly ossified teeth are sometimes cut in the fœtus of only six months.]

It is the opinion of Mr. Fox (*History of the Teeth*, p. 6), that the premature teeth, which are usually the central incisors of the under jaw, are nothing more than the upper parts or crowns of teeth without the apparatus of fangs; that they have consequently a weak attachment to the gums, soon get loose, and produce a considerable inflammation in the mouth of the child, as well as great inconvenience to the mother; and he recommends, accordingly, that they may be immediately extracted. Speaking generally, this account may be correct; but, as there are instances in which teeth of this premature growth possess fangs, and are perfect, it is better to wait before we extract them till some inconvenience arises which may call for their removal.

It is somewhat singular, that the natural growth of the first set of teeth does not seem to be varied, at least according to any general rule, by the degree of strength of the infant; for weakly children often cut their teeth even more rapidly than those in robust health, though the reverse is perhaps more generally the case; and hence the stimulus of irritation, in the process of dentition, very nearly keeps pace with that of healthy vigour.

At this time the gum is often extremely sensible, and, instead of being eased by the pressure of a hard substance, cannot endure the slightest touch. At the base it is florid and distended, but paler and whiter at the edge or upper part; and, when the tooth is on the point of protrusion, seems covered with a flat and whitish blister.

The other symptoms are a repetition of those just described, with a scabby eruption about the lips or head, erythematic inflammation behind the ears, and occasionally spasmodic movements of the mouth and jaws, convulsions, or epilepsy.

The grand point is here to moderate the local irritation. A diarrhœa, or full discharge of saliva, does this naturally, and hence these are favourable symptoms. And if the former be too violent, or accompanied with griping, it should be merely corrected by magnesia or prepared chalk, [or rhubarb combined with ipecacuanha, or hydrargyrum cum creta. If the evacuations are fetid, blackish, or very pale, an occasional dose of calomel, to improve the intestinal secretion, should be given. In particularly obstinate cases, the cautious use of the compound powder of ipecacuanha, with minute doses of calomel, is sometimes adopted. If the milk seem to disagree, the nurse must be changed, and beef-tea, rice-milk, and arrow-root

* Andral, *Anat. Pathol.*, t. ii., p. 160.

given. In many cases, small doses of quinine are useful auxiliaries; but since a moderately lax state of the bowels lessens the risk of worse consequences from dentition, the practitioner should not be in too much haste to check the evacuations; and probably, as Dr. Joy has observed, it should never be done so long as the appetite, sleep, and strength, continue unaffected.] If the bowels be confined, we must employ cooling laxatives; and the discharge of a small quantity of blood from the gums in the first stage, by lancing them, will often afford effectual relief. If the symptoms of oppression or spasmodic action be severe or incumbent, as drowsiness, difficulty of breathing, stertor, or irregular motion of the jaws, antimonial emetics and leeches should be had recourse to, and occasionally repeated; after which, blistering will be found useful, behind the ears or on the back. And when the bowels have been thoroughly emptied, the use of anodynes may be allowed, and will generally prove highly serviceable; though they should be employed with great judgment, and never intrusted to nurses. Hyosciamus, in most of its forms, has often succeeded here, as well as in adult toothache, when judiciously administered.*

In the second stage, or when the teeth are on the point of protrusion, the lancet will often afford immediate relief, not by a discharge of blood, for the upper part of the gum is now become so thin and wasted that little or none will follow; but by giving a direct opening to the tooth, which will frequently make its appearance in the course of a few hours. It is singular, that the use of the lancet should be objected to so generally. The tooth is imprisoned by a membrane that surrounds it on a full stretch, and that is in a state of inflammation. Lancing the gum, or rather the inflamed membrane below the gum, takes off the tension, and sets the tooth free. The pain is slight and transient, and by no means to be compared with the permanent uneasiness which the operation undertakes to relieve. It has been conceived, that a tough indurated cicatrix will be formed if the divided edges of the gum should unite after the lancet has been applied. Yet in the spongy texture of this organ, no such effect is found to follow; but, on the contrary, the recently united edges of the gum, as in all other parts, far more easily give way to the process of absorption than they would otherwise have done; by which means the passage of the tooth is facilitated.†

As the erythematic inflammation which occasionally takes place behind the ears, proves often useful as a revellent, it has also been found sometimes serviceable to imitate it by a friction with savin ointment, or other rubefacients. But

* Among other means, the warm bath, or pediluvium, and opiate frictions on the spine, deserve to be mentioned: the latter are sometimes preferred to narcotics by the mouth.—Ed.

† For some excellent remarks on the morbid effects of dentition, see a paper by Prof. James Jackson, in the New-England Journal, vol. i., pp. 12, 113, 329.—D.

I cannot advise that this or any other eruptions, when produced naturally, should be suffered to run their course without restraint: for I have often known them become a worse evil than the original disorder. In this case, they should unquestionably be exchanged for some other more convenient discharge.*

In cutting the SECOND OR PERMANENT SET OF TEETH, it is not often that much uneasiness is encountered; for, firstly, their progress is much slower than that of the shedding-teeth; and next, the constitution, with the acquisition of a greater degree of strength, is at this time become much less irritable. In a few cases, however, they push forward too rapidly, and urge the shedding-teeth against the superincumbent gums so forcibly as to excite considerable pain; and here a free application of the lancet affords the speediest and most efficacious relief. And not unfrequently the permanent teeth ascend with great irregularity, and press against the crown or fangs of those above them in erroneous directions; whence another source of considerable pain. In this case, the best, and indeed the only radical cure, is to extract the upper or cutting tooth, and thus allow freedom to the under tooth to right itself.—(*De l'Arrangement des Secondes Dents, &c., par M. Duval Broch, 8vo. Paris, 1820.*)

[The milk-teeth occasionally continue in the jaw long after the common period of their being shed; and, as this circumstance does not necessarily prevent the permanent ones from being cut, the jaw seems at first really to contain a preternatural number of teeth; but, in most instances of this kind, the appearance of the permanent teeth is retarded, or they are even wanting; a circumstance fully accounting for the anomaly of the extraordinary continuance of the others.—(*Meckel's Anat.*, vol. iii., p. 242.) The permanent teeth occasion the falling out of the milk ones principally by destroying by their pressure the vessels and nerves of the latter, as well as their adhesion to the alveoli. The destruction of the fangs is not an invariable effect, as the milk-teeth, when they

* The principal disorders accompanying dentition are imputed by Dr. John Clarke, in his commentaries on the diseases of children, to plethora from over-feeding, and to the head being kept too warm. In fact, painful dentition itself brings on a great determination of blood to this part of the body. Hence Dr. Clarke, with the view of preventing bad effects, recommends us to wash the head daily during dentition with cold water, and, if a moderate salivation and lax state of bowels are not present, he directs the use of gentle aperients.

The chylopoietic and respiratory organs, the brain and nervous system, the skin and the lymphatics, are the chief seats of the sympathetic affections occasionally induced by dentition. The best description of a spasmodic affection of the glottis, excited by dentition, is that by Dr. Marsh, in vol. v. of the Dublin Hospital Reports. For an account of a peculiar swelling of the backs of the hands and feet, occasionally brought on by the same cause, consult the writings of Underwood and Dr. Kellie of Leith.—Ed.

are shed, sometimes have those parts very perfect.]—(*Serres*, op. cit., p. 102.)

In the formation, and especially in the cutting, of the third set, OR WISE TEETH, we ordinarily meet with a far more considerable degree of pain and inconvenience, and this too for many weeks; and the pain spreads by sympathy to the ear, which is often more affected than the tooth itself. Such is especially the case where the formation takes place late, and after the jawbones have ceased to grow, and the gum has become thick and callous; for we have here a want of sufficient room, and little power of enlarging it by absorption. In the upper jaw, moreover, the tooth on each side is frequently obliged to incline backward, by which means it presses on the anterior edge of the coronoid process in shutting the mouth, which causes an additional degree of uneasiness; while, in the lower jaw, some part of the tooth continues to lie hid under the coronoid process, and the portion of the gum that covers it is perpetually liable to be squeezed by the tooth below, and the corresponding tooth in the jaw above. In this case nothing but a very free crucial opening will suffice; and often nothing but an excision of a very considerable piece of the callous gum; while there are other instances, in which the evil can only be cured by removing the tooth itself.

We sometimes, though rarely, meet with playful attempts on the part of nature to reproduce TEETH AT A VERY LATE PERIOD OF LIFE, and after the permanent teeth have been lost by accident or natural decay.

This most commonly takes place between the sixty-third and the eighty-first year, or the interval which fills up the two grand climacteric years of the Greek physiologists; at which period the constitution appears occasionally to make an effort to repair other defects than lost teeth, on which we shall have occasion to treat more at large, when describing that variety of decay, which, in the present system, is denominated climacteric.

For the most part the teeth, in this case, shoot forth irregularly, few in number, and without proper fangs; and even where fangs are produced, without a renewal of sockets. Hence they are often loose, and frequently more injurious than useful, by interfering with the uniform line of the indurated and callous gums, which, for many years perhaps, had been employed as a substitute for the teeth. A case of this kind is related by Dr. Bisset of Knayton, in which the patient, a female in her ninety-eighth year, cut twelve molar teeth, mostly in the lower jaw, four of which were thrown out soon afterward, while the rest, at the time of examination, were found more or less loose.—(*Edin. Méd. Comment.*, vol. viii., p. 373.)

In one instance, though never more than in one, Mr. Hunter (*Nat. Hist. of the Teeth*) witnessed the reproduction of a complete set in both jaws, apparently with a renewal of their sockets. "From which circumstance," says he, "and another that sometimes happens to women at this age, it should appear that there

is some effort in nature to renew the body at that time."

He alludes to a restoration of the catamenia, and to the climacteric change, which we shall have occasion to notice hereafter. The author of this work once attended a lady in the country, who cut several straggling teeth at the age of seventy-four; and at the same time recovered such an acuteness of vision as to throw away her spectacles, which she had made use of for twenty years, and to be able to read with ease the smallest print of the newspapers. In another case that occurred to him, a lady of seventy-six, mother of the late Henry Hughes, Esq., printer of the Journals of the House of Commons, cut two molars, and at the same time completely recovered her hearing, after having for some years been so deaf as to be obliged to feel the clapper of a small hand-bell, which was always kept by her, in order to determine whether it rang or not.

The German Ephemerides contain numerous examples of the same kind; in some of which, teeth were produced at the advanced age of ninety, a hundred, and even a hundred and twenty. One of the most singular instances on record is that given by Dr. Slade (*Phil. Trans.*, vol. xxvii., year 1713), which occurred to his father; who, at the age of seventy-five, reproduced an incisor, lost twenty-five years before; and at seventy-seven reproduced another to supply a similar vacancy, so that at eighty he had hereby a perfect row of teeth in both jaws. At eighty-two they all dropped out successively; two years afterward they were all successively renewed, so that at eighty-five, he had once more an entire set. His hair at the same time changed from a white to a dark hue; and his constitution seemed in some degree more healthy and vigorous. He died suddenly, at the age of ninety-nine or a hundred.

Sometimes these teeth are reproduced with wonderful rapidity; but, in such cases, with very great pain, from the callosity of the gums, through which they have to force themselves. The Edinburgh Medical Commentaries (vol. iii., p. 105) supply us with an instance of this kind. The individual was in his sixty-first year, and altogether toothless. At this period, his gums and jawbones became painful, and the pain was at length excruciating. But, within the space of twenty-one days from its commencement, both jaws were furnished with a new set of teeth, complete in number.

The jugglers on the continent, a century or two ago, were in the habit of taking advantage of this occasional playfulness of nature, and offering, as natural phenomena in the formation of teeth, singularities which nature never dreamed of. Thus, a boy was at times started and hawked about the country with a golden tooth, much to the astonishment of both the learned and the unlearned; for though the tooth was in reality a natural one, and only covered over with an inlay of gold, yet the gilding was in one or two instances so exquisitely effected as to deceive almost every spectator, when the trick was first brought forward, and to lay a

foundation for no small number of learned descriptions and profound explanations upon the subject.*

SPECIES II.
ODONTIA DOLOROSA
TOOTHACHE.

ACUTE PAIN IN THE TEETH, OR THEIR INVOLUCRES.

THERE is often a considerable degree of pain of a particular kind that accompanies the irritation of the last species : but it is rarely, if ever, of an acute character ; and is rather a sense of soreness about the tooth than an ache within it : and hence the definitions now offered are sufficiently distinct.

Pain of this kind may be produced by various causes, as a catarrh, or cold ; an exostosis or deposit of earthy matter on the sides of a tooth or its socket ; a caries or decay ; a peculiar affection of the nerves of the sockets or jawbone, acting upon a tooth by contiguous sympathy, and hence not relieved by extracting the tooth that is suspected. It may be produced also by some remote influence, as that of pregnancy, or sordes in the stomach ; by a peculiar diathesis, as that of rheumatism, or scurvy ; by the long use of mercury ; or by a transfer of action, as in some cases of gout, in which the pain is often most vehement and agonizing, and in various instances has produced convulsions, and in others delirium ; or, in the language of the sufferers themselves, has actually driven them mad. In several of these cases, it occurs as a mere symptom of some other disease ; and can only be cured by a removal of the disease that gives rise to it. The following varieties, however, seem well worth attending to, and will generally be found to result from a primary affection ;

- | | |
|----------------------|-----------------------------|
| a Catarrhalis. | From cold. |
| Catarrhal toothache. | |
| β Cariosa. | From decay or caries. |
| Carious toothache. | |
| γ Exostosa. | From ossific deposit. |
| Nodose toothache. | |
| δ Nervorun. | From irritability of the |
| Nervous toothache. | dental or adjoining nerves. |

Every tooth has an internal cavity, which commences at the point of its fang, and enlarges as it ascends into its body. This cavity is not cellular or rugged, but smooth on its surface : it contains no marrow, but appears to be filled with bloodvessels, accompanied with nerves, which must necessarily be derived from the second and third branches of the fifth pair, though they have never been distinctly traced. In the interior of this cavity the teeth appear to be peculiarly sensible ; and hence direct or indirect exposure to the external air ; or, in other words, a carious opening, or a current of

sharp air without such opening (for the air seems in many instances to act through the substance of a sound tooth), will produce acute pain, and is, in fact, the common cause of toothache. The pain thus produced will sometimes cease very suddenly, and especially upon the application of an opiate, or some acrid essential oil. But the irritation is often communicated to the periosteum of the tooth, and thence to the membrane that lines the socket, which is only a duplication of it. And hence, the pain will often become permanent from inflammation excited in these tunics, now thickened and tense, and at the same time incapable of relieving themselves by stretching ; while, if a rheumatic or gouty diathesis prevail, the pain may become intermittent or periodical.

In all these cases, wherever we can trace in the tooth a hole opening externally, the readiest and most effectual modes of cure will consist in stopping up the hole with a metallic or some other substance, so as to defend the tooth from the access of cold ; or in destroying the affected nerve by caustics or cauteries, introduced through the hole itself. The pain may also be occasionally diminished by the application of opium or the more acrid aromatic oils, especially that of cajuput, which is a distillation of the leaves of *McLalca leucodendron*, either directly to the nerve in the tooth, or to the extremity of those nerves in the skin, which are branches of the same pair.* These medicines act by exhausting the sensibility of the nerve : and hence relief is procured by ammonia and rubefacients ; or by a blister behind the ear of the affected side ; by burning the edge of the helix of the ear ; rubbing the cheeks with the *cerambix moschatus*, which possesses a vesicatory power nearly equal to that of the lytta ; holding brandy or hot water in the mouth ; or applying the sedative juices of the lady-bird, or *coccinella septem-punctata*, as well as that of several other insects, to the tooth or gums, after bruising them for this purpose between the thumb and fingers. The root of the *pterisaria alliacea*, or guinea-hen weed, a very acrid plant, is employed for the same purpose by the inhabitants of Jamaica, who put a small plug of it into the diseased cavity.—(*Trans. Stockh. Acad.*, 1644, p. 287.)

So the mastication of various other aromatic or stimulating plants will often produce a similar effect, and especially those that at the same time rouse the salivary glands to increased action, as the bulbs of the alliaceous plants, the root of several of the seselis, particularly the *seseli vulgare*, the common hartwort, or *lasertipitum siler*, Linn.

Such masticatories, however, are chiefly of use in the toothache produced by rheumatism, or where congestion has taken place in the neighbouring parts from inflammation of any other kind. The sensibility of the nerves may hereby, indeed, be in some degree exhausted, but it is the evacuation that principally affords relief. On

* Horstius, De Aureo Dente, Lips. 1695, 8vo. Ingolstetter, De Aureo Dente Silesiaci Pueri, Lips. 1695, 8vo. Tylkowsky, Disquisitio duorum Puerorum, unus cum Dente Aureo, alter cum Capite Giganteo, in Lituania visus. Olivæ, 12mo.

* The oil of the anthemis pyrethrum also, is useful in assuaging the pain of toothache.—D.

this principle relief is also not unfrequently obtained by smoking or chewing tobacco, and, as Dr. Cullen conceives, by the use of camphire (*Mat. Med.*, vol. ii., p. 304); though the camphire and tobacco may partly operate by the sedative power they possess. As errhines promote the same secretion as sialagogues, these have also been frequently employed with considerable success, as well in toothaches as ophthalmias; in both which cases, however, preparations of asarum have generally been found to produce more alleviation than those of tobacco, which is the basis of our common snuffs. A local application of cantharides in powder or ointment is inconvenient, but the tinctura cantharidis may be often used effectually with little trouble; yet the most elegant form of this stimulant for the present purpose is that of the French Pharmacopœia, under the name of Oleum de Cantharidibus. It is made by digesting for six hours, with a gentle heat, one part of powder of cantharides in eight parts of olive oil (*Codex Medicamentarius*, Paris, 1818); the oil thus impregnated is to be filtered, and is then fit for use.

Electricity has also been tried, and occasionally with success. On the continent, magnetism has been a still more favourite remedy; and has at least more writers in its recommendation,* whatever be the actual benefit it may have produced, of which I cannot speak from personal knowledge. Animal magnetism seems at one time, indeed, to have been very extensively employed for this as well as for other severe pains; and, if we may credit the writers of a century or a century and a half ago, with instant and specific effect. The grand magnetiser of the day was the then celebrated Valentine Greatrake, who operated by stroking his hands over the parts affected, much in the same manner as Mr. Perkins of America, not many years ago, employed his metallic tractors.—(Stubbes, An account of several marvellous cures performed by the stroking of the hands of Valentine Greatrake. Lond. 1666. 4to.) And as strong emotions of the mind are well known to produce a more immediate influence on the toothache, than on any other disease whatever, we may readily account for some of the cures hereby produced. Confident hope is as strong a stimulant as terror; and the latter is well known to operate so generally, that it is a rare fact for a person to be actually suffering pain just before the operation of extraction.

The stopping of a carious opening in a tooth should only be attempted when there is no pain; for otherwise the pain will be increased by the introduction of a foreign body. The substances chiefly employed for this purpose, are gum-lac, bees'-wax, sealing-wax, tin, lead, and gold. The metals, and especially tinfoil, are among the most useful, as they afford the best guard, and far less frequently require to be renewed. Yet none of them can be easily retained in cases

where the opening is wider at the top than the bottom; and although attempts have been made to keep them in the proper situation by drilling a small hole through the sides of the teeth, and riveting a proper pin into the metallic substance, they soon become loose, and admit air, food, and other acrimonious materials.

Mr. Fox mentions a compound metallic substance, as far better calculated to answer the purpose of a permanent plug, than any of the preceding. It is obtained by mixing several metals together, which, by the process made use of, become fluid at the temperature of boiling water; on which account it has been called fusible metal. It is supposed that this may in consequence be employed in a liquid state, and thus have an opportunity of striking, before it becomes cool, into all the ramifications of the carious part, so as to fill up the cavity completely, and form a fixture not easily to be detached.

It has often occurred to me that some of the drying earths, employed as cements by our stonemasons, and which harden into an indissoluble plate or mass under water, might be used with more success for this purpose than any other substance; especially tufa or tuffwacke, as Schmeisser calls it, and tarras, which are compounds of iron, alumine, silice, and carbonate of lime. Introduced into the cavity of a carious tooth in the form of soft paste or mortar, they will easily dry, and harden, and adhere, and no moisture of the mouth will dissolve them.

If these methods should not succeed, we may attempt a cure by endeavouring to stupify the nerve of the tooth by a frequent use of hot essential oils intermixed with camphire and opium, or we may destroy it directly by a hot iron. And if these methods fail, and the excision of the crown of the tooth, as practised by Mr. Fay with a pair of cutting forceps, should not be deemed advisable, the only alternative is extraction, which, however, should never be had recourse to till the above plans have been skillfully tried; for, first, the pain may proceed from an affection of the socket, and in this case the pain of tooth-drawing will have been incurred for no purpose; and, next, a carious tooth, whose nerve has been destroyed or rendered torpid, may be of very essential service, as well as ornament, for many years, perhaps through the whole of life. Yet if the caries be accompanied by inflammation in the surrounding parts, the tooth should be removed without loss of time; as the mischief may spread, and the adjoining teeth be hurt.—(*Manuel du Dentiste*, &c. Par C. Maury, 8vo. Paris, 1820.)

In extracting a tooth, a very troublesome hemorrhage will occasionally follow; sometimes profuse and of long continuance. Plater, Schenck, and others, have indeed given cases in which it has proved fatal.* [Mr. Blagden (*Med. Chir. Trans.*, vol. iii., p. 224) recorded the particulars of one remarkable instance, in which the use of styptics, the actual cautery, a plug in the socket, and even a ligature on the carotid artery,

* De la Condamine, Journ. de Méd., tom. xvii., p. 265. Glaubrecht, Diss. Analecta de Odontalgia, ejusque remediis variis, præcipue Magneta. Argent. 1766. Teske, Neuer Versuch in Curirung des Zahnschmerzens vermittelst eines Magnetischen Stahls. Königsb. 1765-6.

* Plater, Obs. Lib. iii., p. 773. Schenck, Lib. i., Obs. 403, 405, p. 99.

failed to suppress the bleeding, which proved fatal a week after the removal of the tooth.] The best ordinary styptic is pressure with an elastic substance, as a piece of sponge covered with wax, touchwood, spunk, or some other spongy bolus, or a dossil of lint dipped in a strong solution of alum or sulphuric acid.* I was not long ago requested to see a young man, who had been profusely bleeding from the gums and socket of an extracted tooth for five days, without cessation, and without sleep, till his wan cheeks and faint, emaciated frame, seemed to indicate that he had scarcely any blood left in his vessels. He was so weak as to be incapable of rising from his bed or taking food; and his stools, from the quantity of blood he was perpetually swallowing, had all the appearance of a melæna. On opening his mouth I found it crammed full of lint wadding, one piece having every hour been added to another, without a removal of the preceding, lest the hemorrhage should be increased, while the blood in which the wadding was soaked, and which had remained in the socket and over the gums for so long a period, was become grumous, putrid, and intolerably offensive.

I first removed the whole of this nauseating load from the patient's mouth, and gave him some warm brandy and water to wash it with. I next directed him to take a goblet of negus with a little biscuit soaked in it, a part of which he soon contrived to swallow. The bleeding still continued; but, as I had no doubt that this proceeded entirely from a total want of power in the lacerated arteries to contract, I applied no pressure of any kind, but prescribed a gargle of equal parts of tincture of catechu and warm water; and the hemorrhage soon ceased.

It is not easy to explain by what means teeth become carious. Out of the body they are indestructible, except by very powerful chymical agents; and yet, in the opinion of many physiologists, they are nearly in the same state in the body as out of it; extraneous substances formed complete at first, without vascularity, growth, or interstitial action, and even destitute of absorbents.

In caries of the bones, observes M. Auzébi (*Traité d'Odontalgie*, &c. Lyons), the decayed part is thrown off, and gives place to a new growth; while, in the teeth, if the enamel be broken, and a caries commence, the carious part is never thrown off, as in the bones, but continues its progress through the parts adjoining; nor can any remedy we know of produce a separation between the part that is sound and that which is unsound. "And we have hence," says he, "a proof that there are no vessels in the substance of the teeth, and that they have a distinct conformation from other bones." Not widely different was the opinion of Mr. J. Hunter, when composing his *Natural History of the Human Teeth*; an opinion drawn from the impossibility of injecting them, the perfection in

which they are produced at first, and their retaining their natural colour after so long a use of madder as food that all the other bones of the body have become thoroughly tinged with it. "But they have most certainly," says he, "a living principle, by which means they make part of the body, and are capable of uniting with any part of a living body; and it is to be observed, that affections of the whole body have less influence upon the teeth than upon any other part of the body. Thus, in children affected with the rickets, the teeth grow equally well as in health, though all the other bones are much affected; and hence, their teeth being of a larger size in proportion to the other parts, their mouths are protuberant." Cuvier, who has adopted all Mr. Hunter's views, has employed the same reasoning (*Dict. des Sciences Médicales*, art. Dents); and M. de Blainville has apparently gone beyond both; for he has denied not only a vascular structure, but even a living principle to the teeth.*

Mr. Fox, however, is said to have succeeded in injecting both the external and internal layer of the dental germ, and even Mr. Hunter himself appears to speak with some degree of hesitation in the treatise before us; and in his subsequent work "*On the Diseases of the Teeth*," offers observations that seem to show he had at that time embraced a different opinion. In the first essay, indeed, he allows that "the fangs of teeth are liable to swellings, seemingly of the spina ventosa kind, like other bones;" but he immediately adds, that "there may be a deception here, for the swelling may be an original formation." Yet, in the second essay, he treats of this swelling as one of the diseases to which the teeth are perpetually liable; he regards the teeth as subject to the common inflammation of other bones, and, like other bones, evincing, at times, great sensibility through the entire substance of the organ, as well as in the central cavity itself.†

Probably some internal action is continually taking place in the teeth, though we are not able to trace it very evidently. The chief causes of a caries are undoubtedly external, but it may be sometimes produced by an internal cause. We have already noticed exposure to currents of cold air, and the medical practitioners of Germany and the north, appeal to the opposite extreme of the habitual use of hot aliments, as a still more general and mischievous source of the same evil. In the Swedish *Amœnitates Academica* (vol. vii., art. 136), we have an elaborate examination of this subject by M. Ribe, who tells us, among other things, that "man is the only animal accustomed to hot foods, and almost the only animal affected with carious teeth." Whence the author takes occasion to condemn, in an especial manner, the custom of drinking hot tea and coffee; and, in accordance with this remark and recommendation, M. Tillæus, another celebrated writer in the same interesting journal, tells us, from Kalm,

* The sulphate of copper will often arrest hemorrhage when other styptics have failed. We have reason to think also, that the nitrate of silver is extremely valuable for the same purpose.—D.

* Nouveau Dict. d'Hist. Naturelle, &c. vol. ix. in verbo.

† At the end of this section, the editor has introduced the chief arguments against the vascularity of the teeth.

in his paper entitled *Potus Theæ*, that the Indians of North America knew nothing of the inconvenience of carious teeth or debilitated stomachs, till tea was introduced among them. There can be no question that the two extremes of heat and cold must be greatly, perhaps equally, injurious to the health; and as little, that the inhabitants of high northern latitudes must suffer more than others from the use of hot aliments, in consequence of the greater coldness of their atmospherical temperature.

To the abuse of hot beverages as a cause of caries, M. de la Salle adds the abuse or excessive employment of sugar; and seems to imagine, that these are the two principal means by which teeth are rendered black in their enamel, and carious in their substance.*

If sugar act at all, it must be by means of the principle of acidity which is contained in it; and, consequently, in proportion to the degree of affinity which this principle bears to the earthy matter or calcareous basis of the teeth and their enamel, beyond that of the acids which enter into their natural composition. And the same may be observed in respect to any other exotic acid whatever.

If, then, we examine the composition of teeth chymically, we shall find, that in their structure they consist very largely of phosphate of lime, with a small proportion of animal matter, and a much smaller of carbonate of lime; and in their enamel, which is altogether of the nature of ivory, that they consist almost entirely of phosphate of lime, with a small proportion of animal matter, and a minute trace of fluuate of lime. And, admitting that the same decompositions take place in an organized living structure, or a simply organized structure in a living frame, as when the principle of life has no concern, we have next to inquire whether there be any acids that have a stronger affinity for lime than the phosphoric, for it is scarcely necessary to extend our research to the carbonic, since this can never be attacked till the enamel into which the phosphoric so largely enters be decomposed, and withdraws its protection.

Now, by examining the tables of elective attractions we shall find that there are four, and only four acids, that precede the phosphoric in their affinity for lime; the oxalic, sulphuric, tartaric, and succinic. We have daily proofs that the teeth, in the living subject, are greatly injured by the frequent or habitual use of several of these acids.† I have at this moment a lady under my care, who till of late possessed as sound and fine a set of teeth as can anywhere be boasted of. From a peculiar delicacy of constitution, however, it has been judged requisite that she should, among other medicines, use a very large quantity of sulphuric acid. This prescription has been continued for many months, and her general health is considerably

established: but, owing to her not having taken all the precaution that is requisite to guard the teeth while swallowing the acid, the pearly enamel is becoming yellow, and its coating very considerably diminished in thickness, so that at the apex of the incisors it is almost as thin as a razor, and is frequently chipping off.

Sugar can have very little effect in destroying the enamel of a tooth; for, though it contains a principle of acidity, it cannot with propriety be regarded as an acid. It may give forth this principle by fermentation, in which case it will form acetous acid; or it may give forth the same principle by distillation with nitric acid, when it will form genuine oxalic acid (for that which exists already formed in the *oxalis acetosella*, or wood-sorrel, is precisely of the same kind); and, in this combination, will evince a stronger attraction for lime than any other acid whatever. But of itself, and without this combination, we have no reason to suppose that its action, if there be action at all, can be otherwise than extremely weak. [General de Beaufort ate a pound of sugar every day for forty years, and lived to the age of seventy. After death his teeth were found to be quite sound.—(*Anecdotes de Médecine*, tom. ii., p. 35.) Plenck kept a healthy tooth in some diluted syrup two months, at the end of which time it had undergone no change.]—(*Doctrina de Morb. Dentium*, p. 52.) If sugar were a solvent of calcareous matter of any kind, it would first show itself in dissolving, and consequently preventing a lodgment of the carbonate or phosphate of lime, which the salivary glands are so continually secreting, and which is perpetually incrusting on the neck of the teeth in mankind, and separating them from the surrounding gums; and hence sugar would be one of the best preservatives against such an encroachment. But as we do not find that those, who use a large quantity of sugar, are freer from this excrementitious matter than those who abstain from it altogether, we have no reason to suppose that it is a solvent of the enamel of the teeth in any material degree.

It will be well to bear these remarks in memory in the composition of dentifrices containing acids of any kind. For the reasons already assigned, the oxalic, sulphuric, and tartaric acids, ought at all times to be sedulously avoided; and hence cream of tartar, which enters so generally into their composition, should in like manner be rigidly proscribed; while those which have the least chance of doing mischief from their very slight affinity for lime, are the citric, benzoic, acetous, and boracic. Yet even these have a stronger attraction than the carbonic acid; and hence, whenever teeth are deprived of their enamel, or the naked fangs become exposed by a decay of the surrounding gums, these also must in like manner be abstained from.

By whatever means a decay or caries of the teeth may be produced, it appears to operate in three different ways; sometimes commencing in the internal cavity, and working its course outwards; sometimes commencing outwards, and working its course within; and some-

* *Journ. de Méd.*, tom. xxxvii., appendix, p. 399.

† As the fluuate and carbonate of lime exist both in the bone and enamel of the tooth, and are even more abundant in the latter than the former part, several acids, besides those specified in the text, must have an injurious effect on the teeth.—Ed.

times by a wasting of the enamel, and consequent denudation of the bony part.* The first, which is the least common affection (its reality being denied by several writers), is discoverable by an appearance of blackness within the whiter surface of the tooth; the third is often to be met with; but the second is the most frequent of the whole; evincing at its commencement the appearance of an opaque white spot through the enamel, which gradually crumbles away about the spot, and thus discloses that part of the body of the tooth which forms the original seat of the affection.

The disease, by its continuance, converts the spot into a hole, and at length destroys the tooth altogether, or at least down to its neck, unless the pain produced by the morbid progress compel the patient to have it extracted before the disease advances thus far.

Caries of the teeth does not appear to be a disease of any particular age, or temperament, or state of health. It exists in infancy and in the firmest manhood, as well as in old age. In the last, indeed, the teeth, that drop out from absorption of their alveoli, are often as sound as when they were first formed; while in childhood, it has sometimes spread from tooth to tooth so extensively, and at the same time produced so much torture, that it has been necessary to extract almost every tooth before the sixth or seventh year. Mr. John Hunter hence conceived, that a decay of the teeth was rather a disease of early, than of advanced life; and that the teeth did not become carious after fifty years of age. Mr. Fox, however, met with several persons, who had not only passed fifty years without having had a caries in this organ, but who had been obliged, after having arrived at sixty, to have several teeth extracted, in consequence of toothache, produced by caries. In some general diseases of the constitution, the teeth seem to possess singular perfection, and even luxuriance. Thus, in phthisis, it is almost a proverbial remark, that the white and pearly gloss of the enamel, which is peculiarly characteristic of soundness, is more than ordinarily clear and bright; while in rickets, in which the whole frame of the bones is shaken, and many of them become soft and spongy, the teeth ascend as firmly and as regularly as if the system were in a state of the most vigorous health.

If the teeth be vascular, there is no great difficulty in conceiving that, like other bones, they may be subject to exostosis, or a deposit of ossific matter on their surface, and particularly on the surface of their roots or fangs; [a case, which the non-believers in the vascularity

of the teeth ascribe to original malformation. What is called an exostosis of the fang, exhibits no irregularities on its surface, as other exostoses usually do; nor is its substance at all different from the rest of the fang. It is, in short, merely an accidental difference of form, where, as the offices of the part require no definite figure, variations in shape are quite common.] The author conceives, however, that, whether the crown or body of the teeth be possessed of secretions in a mature state, they must have absorbents, since we behold their fangs, in very numerous instances, diminished, shortened, and truncated, and sometimes entirely carried away, which it is difficult to conceive can be done by the absorbents of any adjoining organ. And we may lay it down as a general rule, that there is no organ in possession of absorbent vessels, which does not at the same time possess secretions, so as to maintain a balance of action. We find, on extracting a tooth that has long been a cause of considerable pain, that the fangs at least are considerably incrustated with a deposit of ossific matter, so as to give it an appearance of that disease which was formerly but most incorrectly denominated a spina ventosa. And on examining the state of the alveoli after death, we find also that similar morbid apophyses have pullulated occasionally from the face of the alveoli.

Wherever such effects occur, whether in the alveoli or the teeth, a considerable degree of pain, and generally an increasing degree, must be the result, from the pressure of the bony projections against the periosteum or alveolar membrane. At first, this pain is not quite so acute as in carious or nervous toothache, for the imprisoned tunic is not at this time in a state of irritation. But, by a continuance of the pressure, it is soon reduced to this state, when the pain will be as severe as on any other occasion, and far less mitigable.

Wherever we can satisfactorily decide upon the cause, and the complaint is recent, we may often put a check to it by a free application of leeches, and the local use of mercurial ointment, or a mercurial plaster. But in cases of long standing, the only cure is an extraction of the tooth; for even if the disease be seated in the socket, it will be instantly arrested by this process, as the substance of the socket, no longer of any use, will from this time be in a state of absorption, and be at length entirely removed.

There is sometimes a PECULIAR IRRITABILITY IN THE NERVES OF THE TEETH themselves, or of those parts by which they are immediately surrounded, and with which they participate in action, that excites the sensation of severe and even agonizing toothache, without caries or any other concomitant. In this variety, the exact seat of pain is less easily defined than in the preceding; and, there being no black spot or other external mark to direct us to it, the tooth is often mistaken in the continuous sympathy excited, and a sound tooth is extracted in its stead; so that the torture remains unabated. And there are instances, in which the plan of extraction has been followed up from tooth to

* On this subject, Mr. Parry, an eminent dentist of New-York, remarks, "I consider the immediate and exciting cause of dental decay to be always external to the tooth itself, and to consist of certain corrosive menstria, to which these organs are exposed from bodily disease, improper aliments, powerful medicines, and the thousand other sources of acrid filth and destructive poisons, that become concentrated in the mouth and deposited on the teeth."—*Notes to Brown's Dentologia*. New-York, 1833.—D.

tooth without any alleviation whatever, till the jaw has been entirely divested of its teeth on the disordered side.

This is often an idiopathic affection, dependant upon a peculiar irritability, from a cause we cannot easily trace, of the nerves subservient to the aching tooth, or the tunics by which it is covered, or the periosteum, or the fine membrane that lines the interior of the alveoli. But it is more frequently a disease of sympathy, produced by pregnancy, or chronic rheumatism, or disorder of the stomach, in persons of an irritable habit. For this remote or indirect influence it is not difficult to account, when we reflect that the great intercostal nerve, emphatically called the sympathetic, and connected by ramifications with every viscus of the chest and lower belly, is connected also, by its union with a branch of the fifth pair, with the nerves that immediately supply the teeth, and which hence become its indirect extremities.

It is still less to be wondered at that the nerves of the teeth should often associate in the maddening pain of *neuralgia faciei*, or *tic douloureux*; for here the connexion is both direct and immediate. In consequence of this, the patient, in most instances, regards the teeth themselves as the salient point of pain (and they may unquestionably be so in some cases), and rests his only hope of relief upon extraction, although, when he has applied to the operator, he is at a loss to fix upon any one tooth in particular. Mr. Fox gives a striking example of this in a person from whom he extirpated a stump, which afforded little or no relief; in consequence of which his patient applied to him only two days afterward, and requested the removal of several adjoining teeth, which were perfectly sound. This he objected to; and, suspecting the real nature of the disease, he immediately took him to Sir Astley Cooper, who, by dividing the affected nerve, produced a radical cure in a few days.

Where the pain, therefore, proceeds from sympathy, it is of the utmost importance to trace it home to the organ idiopathically affected, for to this the attention should be chiefly directed. Where it exists as a primary disease, it is often of long duration, and difficult removal. Sometimes narcotics, and sometimes stimulants, have been found most successful: blisters have occasionally relieved; and the burning of a little cone of moxa behind the ear, more frequently and more effectually. Of narcotics applied locally, hyoscyamus appears to be one of the best. Its seeds may be put to the cheek in the form of a cataplasm; or their smoke conveyed by a funnel to the tooth itself. In this last form, it will often allay the pain of a carious tooth. Where the pain is remittent or periodical, a free use of bark, with change of air, has proved most salutary.

[From the preceding observations it appears that the author of the present work joins those physiologists who regard the teeth as vascular, and he even carried this belief so far as to express a suspicion, that these organs sometimes undergo an increase of size, whereby the inter-

space produced between two of them, by the extraction of one, may be considerably lessened. In a former edition of this book, he mentioned the fact as having occurred in his own jaw, after the removal of one of the bicuspidati, when he was a boy. That the teeth frequently approach each other, so as to lessen, and even nearly fill up, the interspace occasioned by the extraction of one of them, is an undoubted truth; but the correct explanation of its cause is not the enlargement of the teeth, but the change that follows in the situation of the socket. Hence when a tooth is removed from a young subject, whose jaw is yet growing, the interspace may become in time nearly obliterated. If the gap were filled up by the expansion of the adjoining teeth, this could only happen from the enlargement of the crowns; but though specimens of exostoses and swellings of the fangs of teeth are contained in museums, the editor has never yet met with a tooth, whose crown or body was enlarged.

The question, whether the teeth are vascular, is extremely curious and interesting; and so unnatural is the idea of an harmonious connexion between dead and living substances, that the common opinion of the teeth being furnished with vessels and nerves, is not at all surprising. Nay, the excessive pain often seated in these organs, and the remote, diversified, and very severe disorders, which they appear to excite sympathetically in the animal economy, are circumstances presenting something like a confirmation of the doctrine. Nor can it be denied, that much difficulty occurs in accounting for certain changes in the teeth, unless this doctrine be admitted. But it is not because we cannot explain precisely the nature of every particular alteration or appearance of these organs, without supposing them to be vascular, that they must really be so; for, if some of the phenomena in question take place also in artificial teeth, and in teeth which have been boiled, or kept so long in a drawer as not to admit of the suspicion of their being alive, the doctrine then immediately becomes a questionable hypothesis.

The difficulty of accounting for caries of the teeth, and for the absorption of their fangs, unless the belief in the vascularity of these organs be adopted, seems to have had great influence in determining the author of the "Study of Medicine" to consider the substance of the teeth as vascular. That he was also correct in his notice of the disagreement between Mr Hunter's Natural History of the Human Teeth and the Essay on their Diseases by the same distinguished man, is a truth, of which no person who has read these works can doubt. The subject was difficult,—so difficult as even to involve Hunter in hesitation, if not contradiction. Our author has not mentioned, however, some of the principal facts and arguments which such modern physiologists as disbelieve the vascularity of the teeth generally bring forward: a short account of them in this place may not, therefore, be uninteresting.

In the second edition of this work, it was re-

marked by the author, that, "admitting the soundness of Mr. Hunter's experiments, and the accuracy of his reasoning, it seems impossible that the teeth, when once perfectly produced in the gums, should ever decay; for no action of the living principle can occasion a secretion of those chymical agents which would alone, in such case, be capable of destroying them." We have seen, also, that our author describes one form of caries as beginning within the tooth. Others, however, deny the reality of the latter case, and, if they are right, the answer is at once given to the foregoing argument. They distinctly allege that caries never begins within the tooth; but a speck is first seen upon the enamel, a portion of which being destroyed, the decay extends to the bone of the tooth, and proceeds from the surface into the cavity. As soon as the bone begins to be affected, the progress of the decay is much more rapid; an excavation is produced; and the enamel is left in the form of a hollow shell. The following considerations are mentioned as proofs, that the decay is not the effect of vascular action. It first attacks the enamel, which is confessedly not vascular; for though Bichat regarded this substance as sensible and organized, because acids set the teeth on edge, the fact is, that the disagreeable sensation, here adverted to, is not situated in the enamel itself, nor is it ever excited by an acid merely applied to it. The acid must at the same time come into contact with the organ of taste, or extend its action directly to the sensible parts within the cavity of the tooth.

Throughout the whole process of caries, there is no attempt at reparation. Artificial teeth are as much subject to decay as natural ones. The discoloration has, indeed, been sometimes thought to be more deep in the artificial teeth made of the tooth of the hippopotamus, than in the human teeth; but, in ingrafted human teeth, the decay is acknowledged to be precisely similar to that of the natural ones.

The alleviation of toothache by the application of muriatic acid, nitrate of silver, and other caustics to the carious surface, has been esteemed a proof that the caries is an ulcer, and that its irritability may be destroyed by such treatment. Since, however, the remedies may act upon the exposed vascular contents of the cavity of the tooth, or may affect these contents by penetrating through the thin medium which remains, it is manifest that they can afford no proof of the point in question. At the same time, it is to be taken into the account, that toothache from caries may frequently be relieved by a plan nearly amounting to a demonstration, that the pain does not arise from the ulcerated surface, but from the nerves in the cavity; namely, let the decayed hole be stopped up (which is rather a rude method of treating an irritable ulcer), so as to prevent the access of the external air and of foreign bodies, and the pain will cease.

The writer, from whom the editor has borrowed these judicious reflections, further observes, that it is not perhaps so easy to deter-

mine what the decay is, as what it is not. Those who consider the teeth as destitute of vessels, ascribe their decay to the chymical action of the secretions in the mouth, and of the articles of food. Here it is difficult to comprehend how a cause which must necessarily be so general in its application, should be so circumscribed in its effects; never producing decay at once in an extensive surface, but in its commencement, limiting its action to a small spot. However, in artificial teeth, a large surface sometimes decays under circumstances favouring an accumulation of fluids in a particular part; viz., the portion that corresponds to the gum, and is usually grooved, and also the lateral parts of such teeth.

Various considerations strengthen the inference, that the decay of the natural teeth must depend upon a chymical and not a vascular operation. It commences in those situations where food or extraneous matters are most liable to lodge, as between the teeth, and near the neck, just where the gum adheres. It is checked by stopping up the hole, and preventing the entrance of the food and secretions of the mouth into it. It is most frequent in the higher classes of society, whose food is of the most unnatural and miscellaneous kind. It is very rare in the teeth of savages, and it is alleged never to occur in animals. In twelve or fourteen skulls, discovered in two barrows opened in Gloucestershire, not a single decayed tooth was noticed. Now, as this mode of burial has not been employed for the last six centuries, these skulls must have belonged to a time when the modern habits of luxury, in respect to food, were unknown; and when the effects of such habits on the teeth were, of course, not discernible. One fact connected with the foregoing statements, and perhaps in some degree throwing a doubt on part of them, is the extraordinary prevalence of caries of the teeth in particular families, seemingly as if there were some original hereditary imperfection in them, whereby the causes of caries, whatever they may be, very readily produce their destructive effects. Another fact, universally acknowledged, is the frequent and almost regular occurrence of fine sets of teeth in certain families through a long series of years; a circumstance that seems, like the preceding one, to imply some hereditary differences in the degree of perfection of these organs. That persons who smoke tobacco generally have discoloured, carious teeth, is a fact universally recorded. Perhaps, therefore, the ingenious author of the present work was mistaken in supposing, that the production of caries of the teeth could not be chymically accounted for, unless the secretion of chymical agents within them were admitted as a fact, which fact would, of course, imply vascularity. The caries, instead of beginning sometimes internally, as he supposed, always commences externally in the enamel, and proceeds from it into the bone of the tooth, so that the fluids, and other matters in the mouth, have direct access to the affected surface. An inward decay of the teeth, with the whole shell of enamel perfect, is talked

of by dentists; but, though the external aperture may be minute and concealed, its existence must not be denied, until a contrary case can be fully demonstrated.

Our author supposed that madder and anatomical injections might not be sufficiently attenuate to enter the vessels of the teeth, and was not disposed to receive the fact of those substances not entering them as a proof of their non-existence. Certainly, in several instances, to conclude that parts are not vascular, because the vessels cannot be injected, would be decidedly erroneous. But in these particular cases, the phenomena of disease enlighten us and correct our judgment; which can hardly be said to occur with respect to the teeth, for their changes, whether vital or chymical, are enveloped in the deepest mystery. As for the experiments with madder, however, they furnish the strongest argument of all against the vascularity of the fully formed substance of the teeth, without even affording the least room for the argument, that madder is not subtle enough to enter the vessels of those organs. This will be immediately evident, when it is recollected, that while the tooth of a young animal is only partly formed, if madder be given with the food, it is really transmitted by the vessels of the pulp, not indeed to the portion of the tooth already complete and void of vessels, but to that part of the organ which is developed subsequently to the beginning of the experiment, and is the work of the vessels of the pulp. Here, however, a most interesting fact was pointed out by Mr. Hunter; namely, that when the tooth of a young animal has thus been tinged with madder, the stain is never afterward removed, which is exactly the reverse of what occurs in bones died by feeding animals with the same substance. The bones, therefore, must have vessels for the conveyance of the madder into them, and other vessels by which it is again removed from them. On the other hand, though the vessels of the pulp seem capable of communicating the red tinge of madder to the bone of the tooth upon its first deposition, they appear directly afterward to have no further communication with the new formation, which remains incapable of every change usually produced in other parts through the medium of arteries, veins, and absorbents.

These conclusions, deduced from experiments with madder, may be set down as firmly established, without being at all weakened by an observation made by the late Mr. Gibson; namely, that the fact of the power of madder to redden the bones is no demonstration, that a continual renovation of their particles takes place.—(*Mem. of the Lit. Soc. of Manchester*, 2d series, vol. i., p. 146.) Madder communicates to the bones a red tinge, which is afterward gradually removed: these two facts prove, at all events, an interstitial action, as far as that substance is concerned, and thus are explicable only on the principles of vascularity and life. Just so the communication of a red tinge by madder to the phosphate of lime of a tooth that is undergoing development, is a

tolerably convincing proof, that vessels then deposit both the earthy and the colouring matter; while the permanency of the tinge as clearly shows, that the coloured particles of lime in the tooth are not absorbed again, and that no vascular interstitial changes afterward occur.

In confirmation of the preceding view, it deserves particular notice, that the teeth never exhibit any appearances of reparation under circumstances of accidental injury or supposed disease. The loss of substance occasioned by the friction of mastication is not repaired; a part broken off is not renewed, but the fractured surface remains unchanged; a hole caused by decay is never filled up again. The union of a fracture near the neck of a tooth, even if it be possible, as M. Duval* and others declare, does not at all invalidate the foregoing statement, because the union is ascribed to the action of the pulp, and not to that of vessels within the substance of the tooth itself.

The non-existence of vessels in the teeth may be inferred from another particular case; a violent blow sometimes causes a general discoloration of a tooth, as if blood were effused through all its texture. This appearance is explicable, either by supposing vessels to exist in the substance of the tooth, which pour out the blood in consequence of the injury, or by supposing that the vessel in the fang is ruptured, and that the extravasated blood mechanically discolours the substance of the tooth. If the former explanation be adopted, the colour ought not to be permanent; for wherever there are arteries, there must also be absorbents; and these ought to remove the effused blood, as they do in bruises of the soft parts. By the other explanation we gain a satisfactory solution of the difficulty; we account for the duration of the colour in the tooth in the same manner as of that which arises from feeding a young animal with madder.

The teeth are exempted from all those diseases which ravage the bones: † lues venerea, scrofula, and rickets, which attack all other bones, never produce the slightest effect on the teeth, which remain unaffected even in cases of *mollities ossium*, where all the other earthy matter of the system is absorbed.‡ In short,

* Dict. des Sciences Méd., tom. viii., p. 335.

† This assertion is too unqualified. The influence of constitutional causes, even of adventitious origin, and the effects of hereditary peculiarities, on the healthy or disordered condition of the teeth, may frequently be observed. The teeth of scrofulous persons, and the detrimental effects of the abuse of mercury on the teeth of some individuals, have been remarked by many writers. In *mollities ossium*, the teeth sometimes participate. A case of this is stated by Veirac, *Abhandlung über die Rhachitis*, pp. 54, 83.—Stendal, 1794. See, also, *Isenflam, Versuch einer prakt. Anmerkungen über die Knochen*, p. 427. A tooth resembling cartilage was found by Krauss in *Misc. Acad. N. Cur.*, 1697, p. 619. In the museum of Blumenbach is the back tooth of an animal, which, excepting the root, has completely expanded into a large bony tumour. Meckel has figured a similar case of a human tooth, tab. 7, figs. 8, 10.—D.

‡ The museum at Leipsic, it is said, contains

the teeth never have the slightest participation in the general affections of the constitution. Their substance also never swells from inflammation; it never throws out a fungus or exostosis; for what has received this name is in all probability an original malformation, as Mr. Hunter first suggested.* Ossific depositions may be conceived to arise from the vessels of the pulp, or those of the membranous lining of the fang, so as to lessen, or even obliterate, the cavity or canal; a change said to happen in old age, without supposing any part of the change to result from vessels in the substance of the bone. The same substance never exfoliates. Whole teeth are sometimes included in an exfoliated portion of the jaw; but then they are not altered in structure or appearance, which is another proof of their want of vascular connexion with the rest of the body. If, says a well-informed writer, it be said that these teeth are dead, like the bone which contains them, we would ask, what are the distinctions in appearance between a dead and a living tooth? Are they to be ascertained by inspection in the living body, or can they even be demonstrated by anatomical investigation? The absorption of the fangs of the temporary teeth cuts off the vessels long before these teeth are actually shed; yet there is no sign nor character by which a tooth whose vascular supply is thus intercepted, can be distinguished from another in which it remains unimpaired.—(Rees's *Cyclopædia*, art. *Cranium*.)

As is remarked by the same author, the difference between the growth of the teeth and that of the bones is particularly striking. In the cartilaginous epiphysis of a young bone, vessels are seen entering from all sides; in the centre there is a small bit of bone, of a loose and spongy texture, which can be made quite red by injection. We can trace this hardening through every intermediate stage, to that of perfect bone, the vessels of which, even in its most compact state, are still easily demonstrable. Let us compare with this the growth of a tooth. If we examine it at ever so early a period, when a speck of ossification only can be discerned, the part which is thus formed is complete, and has all the properties which belong to the bone of the perfect tooth. It does

examples of ankylosis of the teeth with the jaw, taken from rachitic subjects, and likewise other preparations illustrative of the fragility of the teeth in individuals of a similar constitution.—(Cyc. of Pract. Med., art. *Dentition*.) But it appears to me that as fragility of the teeth is by no means common in rachitic patients, and is sometimes observed in other persons, it can hardly be regarded as an unequivocal effect of rickets.—Ed.

* Soemmering and Fox each saw a case where several of the teeth were consolidated into one mass; and Dr. Joy met with a similar instance in the museum at Leipsic, of two incisors grown together by their crowns, while the roots were separated. These abnormal appearances he refers to the deficient evolution of the alveolar septa.—(Cyclop. of Pract. Med., art. *Dentition*.) In speaking of *Odontia Deformis*, we shall introduce some other explanations of this point.—En.

not undergo that gradual development which is seen in the growth of bones; but the smallest point, when once formed, never alters. In cartilaginous epiphyses, the central portion of bone is imbedded in the cartilage: numerous vessels can be traced into it on every side; while in a tooth, the ossification does not go on in the centre of the pulp, but the bone covers it like a shell. The connexion between them is merely that of contact of surface, and there is no discoverable vascular union.

If any argument be drawn in favour of the vascularity of the teeth, from the fact of blood being sent into their cavity, it must be immediately weakened by the reflection that the intention of various other arrangements in the structure of the body is completely mysterious. Thus, we know as little why male animals have mammae and nipples, as why the cavity of a tooth should contain vessels apparently for no purpose.

With respect to the circumstance of a yellow colour being communicated to the bone of the teeth in jaundice, it is no proof of their vascularity. As is well remarked, the argument would prove too much. The vessels of the teeth, if any such exist, are so minute that they neither convey red blood nor coloured injection; yet they are capable of carrying so much bile as to tinge the tooth of a uniform yellow to a certain distance from the cavity. If this colour be then owing to a yellow fluid contained in vessels, these must be so numerous as to render the tooth much more vascular than any other bone. The fact is, that the vessels of the pulp contain bile, and die this part of a uniform yellow colour, which is mechanically imparted to the adjacent bone in the neighbourhood of the cavity; the effect gradually ceasing at a little distance from it. The stain is produced, just as it is by immersing the teeth in bile after death.

Another proof of the vascularity of the teeth, is attempted to be taken from their successful transplantation from the jaw of one person to that of another, or to parts of another animal's body, as the comb of a cock. These experiments, however, will succeed with dead teeth. The writer of the article *CRANIUM*, in Rees's *Cyclopædia*, was shown a cock, in whose comb the late Mr. Moor, the dentist, had inserted a tooth that had previously lain many months in a drawer; and it was firmly adherent. This adhesion then does not seem to require even the living principle, of which it was regarded by Mr. Hunter as a proof.

But no arguments have been more confidently employed by the believers in the vascularity of the teeth, than those deduced from comparative anatomy. Animals of the class *gires*, as the beaver, hare, rabbit, squirrel, rat, mouse, &c., have two very large incisor teeth in each jaw, which, being employed in cutting various hard bodies, wear down very rapidly. Hence, if these animals be kept entirely on soft food, their teeth grow out to a great length, and sometimes assume very ludicrous shapes: and if these teeth be lost from one jaw, the opposite

ones grow out in the same way.* This constant growth is effected in the same manner as their original formation. They are hollow, and contain a pulp, which continues to deposit fresh substance below, in proportion as their upper part wears away. The tusks of the elephant and hippopotamus have a similar power of growth. It seems now, indeed, to be the common belief of some of the first physiologists, that the teeth really present a strong analogy in their development to the hair, nails, and horns of the animal body, and also, as M. Geoffroy St. Hilaire has fully ascertained, to the beaks of birds. In the human subject, the process by which the teeth are formed confirms this doctrine; but, as we have noticed, what happens in the incisor teeth of the gnawing animals is a still closer analogy, since the pulp retains for an indefinite period the power of secreting additional matter, by which the effects of the loss of the tooth at its cutting end are counteracted, and an incessant tendency to elongation, or growth, kept up in the organ. A list of distinguished authorities, and a brief notice of some of the arguments in support of this physiological view of the nature of the teeth, are given by Meckel.†

Bullets have been found imbedded in the tusks of elephants. Now, the advocates for the vascularity of the teeth have argued that the closure of the opening, by which the ball entered the tusk, and the swelling sometimes observed in these cases opposite the foreign body, could not have taken place without the agency of vessels. However, these occurrences are now satisfactorily explained, without having recourse to this hypothesis. The tusks are constantly growing, during the animal's life, by a deposition of successive laminæ within the cavity, while the outer surface and the point are gradually worn away; and for this purpose the cavity is filled with a vascular pulp, similar to that in which the teeth are originally formed. If a ball penetrate the side of a tusk, cross its cavity, and lodge on the opposite side, it will

* This remarkable growth is sometimes the consequence of a mere change in the direction of the teeth, without any of them being absent. In the head of an old rat, presented to the Royal Academy of Medicine, Andral noticed the following disposition of the incisors:—The upper right incisor had scarcely shown itself out of its socket, when it inclined obliquely downwards and backwards into the mouth; and, having reached the posterior opening of the nasal fossæ, it turned upwards and entered the left cavity of the nose. After reaching the nostril, it next perforated the upper jawbone, insinuating itself into the socket of the adjoining incisor tooth, and now changing its course again, terminated in a point below the left orbit. The two incisors of the lower jaw were also curiously lengthened and twisted; and one of them, after passing close to the left eye, which it had destroyed, came in contact with the skull, and seemed ready to pierce it. *Anat. Pathol.*, t. ii., p. 266.—Ed.

† *Anat.*, vol. iii., p. 234. See also *Mém. sur l'Accroissement continué et la Réproduction des Dents chez les Lapins*, &c., par M. Oudet, in *Magendie's Journ. de Physiol.*, tom. iii. et iv.

become covered towards the cavity by the newly-deposited layers of ivory, while no opening will exist between it and the surface, to account for its entrance.* All the various appearances attending the lodgment of bullets and pieces of other weapons in the tusks of elephants, can be accounted for by the power of the pulp connected with these organs.

The absorption of the fangs of teeth is no proof of absorbents in them,—the fact only showing that those parts are capable of being acted upon by the organs of absorption, which may be situated in the alveoli, or in the cavities of the fangs, without being actually in the substance of the bone of the tooth.]

SPECIES III.

ODONTIA STUPORIS.

TOOTH-EDGE.

TINGLING UNEASINESS OF THE TEETH FROM GRATING SOUNDS, OR FRICTIONS.

THERE is sometimes a peculiar sensibility in the teeth or their sheaths, that induces a kind of vibratory pain, in which they are colloquially said to be SET ON EDGE; and that in two ways as follows:—

- a A stridore. From jarring noises.
 ß Ab acritudine. From vellicative or acrid substances.

In many cases the teeth sympathize with the ear, on an exposure to harsh, dissonant, or stridulous sounds, as the grating of a file, the creaking of a door on its hinges, or of a swinging sign in the street.

The same effect is produced whenever the teeth are vellicated by smooth substances, as a piece of silk or velvet, or exasperated by acid or other acrid materials.

To explain these effects, it is necessary to observe in the first place, that a close reciprocity of feeling is at all times maintained between the teeth and the tympanum of the ear, by a union of their respective nerves; as one of the branches of the seventh pair, destined to supply the tympanum, anastomoses with the lingual branch of the fifth, which sends offsets to the teeth: by which means the latter become indirectly an organ of sounds, as well as of mastication. It is for this reason, among others, that deaf persons open their mouths to catch up speech they cannot otherwise hear; and that, as already observed, when the wise or adult teeth are about to be cut, the tympanum not unfrequently endures more pain than the gum or membrane by which the tooth is covered; and hence, the tuner of a musical instrument is often in the habit of applying his tuning-pipe to his teeth, as soon as he has put it into a state of vibration, to determine the more accurately upon its pitch.

Now, as the last action is a source of pleasure to the teeth, from the vibrating tone proving agreeable to the ear, we can readily see why tones or sounds of any kind that are hateful to the ear, should be hateful also to the teeth.

* See *Rees's Cyclopædia*, art. CRANIUM.

This is the general principle : and it is sufficient to explain why all persons are in a certain degree subject to the tooth-edge, upon an exposure to the more common causes that produce it. But in constitutions of a peculiar kind, or where the ordinary association between the two organs has been specially and habitually cultivated, or some early and very powerful impression has been even accidentally communicated from the one to the other, the sensation of tooth-edge will be produced far more frequently and acutely than in other cases. And when, in such persons, the teeth are in a state of preternatural sensibility from any kind of diseased action, or from irritating substances applied to them and the gums, as acerb or acid juices, the sensation may become so acute as to be intolerable. Bartholine (Epist. IV., p. 523) has recorded a case, in which the sharpening of a knife so highly excited not the teeth only, but the surrounding gum, that, along with a very sensible jarring of the teeth, a profuse hemorrhage from the gum was occasioned.

In many instances, the power of the imagination alone, from a long habit of association, is sufficient to call up a very considerable degree of this painful feeling ;* as when we see a knife drawn across a china plate, though so gently as to produce no sound whatever ; and there are instances of persons in a high degree of excitement, who, by this action alone, have been suddenly thrown into convulsions.

While this affection is permanent, or very frequent and troublesome, and proceeds from a morbid state of the teeth or their involucre, our attention must be particularly directed to the nature of the cause with a view to its removal : if the gums be inflamed, spongy, or otherwise irritable, scarification will often be found serviceable : and if the disease be seated in the body of the teeth, several of the remedies recommended under the preceding species, may have an equally good effect in the present case. If it be a symptom of some other complaint, it can only be removed by a removal of the original disorder. Forestus (Lib. xiv., Obs. 9), Baricelli (*Hortus Genialis*, p. 337), and others, assert, that relief may often be obtained by chewing purslane leaves. When it is the mere result of an association of ideas, or of great strength of sympathy, with an ear delicately alive to harmony of sounds, it is best cured by an habitual exposure to the cause of the affection, which gradually blunts the feeling. The grating sound produced by filing a saw, was probably at one time harsh and abhorrent to the ears of the sawyer ; but, by being inured to it, he at length hears it with indifference.

SPECIES IV.

ODONTIA DEFORMIS.

DEFORMITY OF THE TEETH.

TEETH IRREGULAR IN SHAPE, POSITION, OR NUMBER.

DEFORMITIES of the teeth are for the most part produced naturally and in early life. Either

* Darwin, *Zoonom.*, sec. xvi. 10. & cl. iv. 1, 2, 3.

set may be too large or too small, or some of them much larger or smaller than the rest, or they may be irregular in their line of ascent. They may be misplaced by incurvation, or projection, or obliquity. They may be crowded and confused, or, as has sometimes occurred, be multiplied in crops of double or triple rows.* In all these cases, they cannot too soon become a subject of artificial arrangement, which in young persons may accomplish much, and often, by skilful management, not only correct the error of shape or number, but give a proper inclination, not merely to the teeth, as they start from their natural line, but even to the misshapen sockets.

Many of these irregularities proceed from a natural excess or deficiency of the calcareous matter which enters into the structure of the teeth. This has been sometimes so defective as to leave the teeth cartilaginous, or possessed of their animal part alone : and, in a few cases, as I have already observed, to retard the appearance of even the first set till ten or twelve years of age. [Plenck extracted from a girl, seven years of age, a canine milk-tooth of the lower jaw, which was livid, as soft as cartilage, and compressible by the fingers, especially at the fang.]† But the opposite extreme is by far the most frequent ; and where this exists in a considerable degree, we not only find occasionally all the irregularities already noticed as resulting from plurality, but sometimes inseparable union between the teeth and their sockets, so that it is impossible to extract them without fracturing the sockets ; sometimes a perfect continuity or coalition between all the teeth,‡ insomuch that, in one instance, the whole was found to constitute a single bone or curb of ivory.§ Then again, we sometimes meet with a production of teeth in other parts of the mouth than the gums, and particularly in the palate, of which examples are to be found in Schenckil and Borelli.¶ Albinus records an instance, in

* Bloch, *Medicinische Bemerkungen*, p. 19. For others, see *Nosolog.* in loc.

† *De Morb. Dentium*, p. 39.

§ Schenck, lib. i., Obs. 412. Andral, *Anat. Pathol.*, t. ii., p. 262.

|| Schenck, lib. i., Obs. 411.

¶ Cent. ii., Obs. 81. The supernumerary teeth, which are formed independently of the regular ones, may be in the same line with them, though this is rare. Thus, Soemmerring saw five incisors in the upper jaw. Meckel mentions one instance, in which a rickety girl, fifteen years of age, had small bony points, resembling denticulations of fish, interposed between the regular teeth ; and Tesmer met with an individual, whose upper jaw contained four supernumerary molar teeth, arranged in the same line with the others ; three on the right side, and one on the left. In general, supernumerary teeth are not in the same line with the rest : they may be directly behind the incisors, or scattered over the roof of the mouth. Sandifort recites a case, in which there were thirty-six teeth in each jaw. Supernumerary teeth are more frequently noticed in the upper jaw than the lower ;

which a canine tooth grew in the substance of the nasal process of the jawbone below the orbit.*

Another cause of irregularity in the ascent of the permanent teeth is an inaccordance of time or manner, in the absorption of the fangs of the first set of teeth, and the protrusion of those of the second set. As the latter fangs are thrown forth, the former, in all cases of regularity, are carried away: and hence the permanent teeth, pressed forward by the gradual prolongation of their fangs, bear before them the mere crowns of the shedding-teeth, and find little resistance to their ascent. In former editions, the author referred to these circumstances in proof of the vascularity of the teeth; observing that, as the fangs pullulate from the bodies of the teeth, the latter parts must have vessels. The truth is, however, that the fangs are formed from the vessels of the prolongations of the pulp.] Now, if the fangs of the upper set be not sufficiently carried off, or, in other words, the crown of the teeth be not sufficiently detached and set at liberty, as the under set, or any particular teeth in the under set, press forward, the latter must necessarily be thrown out of their proper line, and rise within, or without, or wherever they can force their way.

The second set of teeth is also wider than the first; and hence, with the exception of the bicuspidati, which from this very circumstance rise under the shedding molares, every single tooth in its ascent must be opposed to more than a single tooth above it; whence another source of difficulty, and often of irregularity. In consequence of all which, it is rather to be wondered at, that we do not meet with more frequent instances of deranged or misshapen teeth than actually occur to us. And nothing can be clearer, than the necessity of a close and skilful watch over them during the shedding season, so as to remove any of the first set when they form an undue degree of resistance to the permanent, and have a tendency to throw them out of their proper line; and any of the second set that may exceed their proper number, and, by their surplus, crowd and misplace the rest.

and the cutting and canine teeth are more commonly redundant than the molar.—See Andral, *Anat. Pathol.*, t. ii., p. 263.—Ed.

* *Annot. Acad.*, tom. i., p. 54. The reference of these various cases simply to redundancy of calcareous matter, is not altogether satisfactory, inasmuch as no redundant tooth can be formed without some peculiarity in the pulp. An extraordinary number of teeth may occur under three circumstances: the milk teeth may not drop out in proportion as the permanent ones rise; 2dly, true supernumerary teeth may be formed; 3dly, a second development of the same tooth may take place. The first case requires no comment; in the second, there may be either an aggregation of several germs, and the supernumerary teeth united to the regular one; or these may be completely separated from it; or a prolongation may be sent off from the regular tooth, giving it the appearance of being double.—See Andral, *Anat. Pathol.*, t. ii., p. 263.—Ed.

SPECIES V. ODONTIA EDENTULA. TOOTHLESSNESS.

LOSS OR WANT OF TEETH.

This is also a very common affection, and offers the following varieties:—

α Peculiaris.	From constitutional defect.
β A vi extrinseca.	From external violence.
γ A carie.	From decay.
δ Senilium.	From old age.

As the teeth are often produced supernumerously, so are they often naturally deficient in number. [Sometimes the germs of the permanent teeth are either wanting, or are not developed, and then the milk-teeth are in certain instances not shed during life, but merely diminish in size from the effect of a larger attrition than what they were designed to bear. In other cases the milk-teeth are shed as usual, but not replaced. Lastly, examples occur, in which no teeth whatever are produced, and individuals have been known to reach a very advanced age, without ever having had a tooth in their mouths. If the edge of the jaws of persons thus circumstanced be examined, it will be found to be of a fibro-cartilaginous consistence, like the hard substance noticed in infants which have not yet cut their teeth; or like what is reproduced in old persons, or that which always exists in ruminant animals in the places where their jaws are naturally destitute of teeth.—(*Andral, Anat. Pathol.*, t. ii., p. 261.) But, the absence of teeth in man may be only partial; and, in this case, there is a difference in the frequency of the defect in relation to the kinds of teeth.] The dentes sapientiæ, which are the last cut, are those which are most frequently not produced at all; however, there is hardly any particular tooth that has not sometimes failed in its development. This is sometimes the case with the bicuspidati, as it is not uncommon to meet with a person in whom one, two, or more of these, have never made their appearance. But it occurs more frequently in the incisors, particularly of the lower jaw: and Mr. Fox refers to an instance, in which this defect appertained to several individuals of the same family, none of whom had ever cut these incisors. [In one example on record, there were only four permanent teeth in each jaw, and in another, only a single incisor in the upper jaw.]—(*Fox on the Teeth. Sabatier, Anat.*, tom. i., p. 78.)

But the other varieties of cause are more obvious and common: being

Violence, by which they are suddenly misplaced, or knocked out;

Caries, or inflammation of the surrounding sheaths, by which they become loosened in their sockets; and

The natural absorption of their sockets in advanced life.

In many instances, therefore, the separated teeth are in a sound state; and, in a few instances, where the alveolus is also perfect, and the tooth has only been out of it for an hour or two, so that its living principle has not alto-

gether ceased, it may be replaced, and will take a fresh hold and become serviceable for many years; though it rarely, perhaps never, forms so firm and permanent an attachment as before the accident which threw it out.

Mr. Hunter extended this mode of supply to a transplantation of teeth from other persons: and, at one time, this method also was carried to a considerable extent of practice. Too much caution, however, cannot be employed in ascertaining the health of the individual by whom the scion tooth is to be furnished; for syphilis, and other diseases, may be transplanted at the same time. As an instructive case upon this subject, I may refer to the following, drawn up by Dr. Watson, and inserted in the *Medical Transactions*.—(Vol. iii. art. xx.) An incisor tooth of the upper jaw, from an unknown cause, becoming carious in a young unmarried lady about twenty-one years of age, it was extracted, and the place very dexterously supplied by a like tooth from another young woman, who, upon examination for the purpose, appeared to be in good health. The scion tooth very rapidly took a firm hold, and soon bid fair to be of great service and ornament. In about a month, however, the mouth became painful, the gums inflamed, discoloured, and ulcerated. The ulceration spread very fast, the gums of the upper jaw were corroded, and the alveoli left bare. Before the end of another month, the ulceration stretched outwardly under the upper lip and nose, and inwardly to the cheeks and throat, which were corroded by large, deep, and fetid sores. The alveoli soon became carious, several of the teeth gradually dropped out, and at length the transplanted tooth, which had hitherto remained firm in its place.

About this time blotches appeared in the face, neck, and various parts of the body, several of which became painful and extensive ulcers; a considerable degree of fever, apparently hectic, was excited; a copious and fetid discharge flowed from the mouth and throat, which impeded sleep; and the soreness of the fauces prevented a sufficiency of nourishment from being swallowed.

The wisest plan would probably have been to have commenced from the first with a mercurial process, before the system had been so far debilitated, and the general health so deeply encroached upon, as to render any plan of very little use. An antiseptic course, however, of bark and other tonics, was first tried and persevered in, till found to be of no service whatever; and calomel pills in an alterative proportion were then had recourse to in their stead. This plan was found to soften every symptom, and totally to eradicate many; but the bowels were soon affected with severe pain and purging; and the calomel was exchanged for strong mercurial ointment; which, from the present debility of the patient, soon produced a like effect, and an effect that could not be corrected by opium; and, in the end, the patient fell a victim to the experiment. The person from whom the tooth had been taken, had, in the meantime, continued in perfect health; and, upon a minute

inspection, as well of the sexual organs as of the mouth, evinced not the slightest syphilitic affection.

The case is mysterious, and leaves much ground for the imagination to work upon. If it be difficult to conceive it to have been syphilitic, it is more difficult to conceive it to have been any thing else. But the grand lesson to be learned from it, on the present occasion, is that of the wariest caution, and a caution amounting almost to a prohibition, in remedying a deficiency of teeth by transplantation.

Other cases might be advanced, but it is unnecessary. Mr. Hunter, partial to his own invention, endeavoured to account for most of these upon the principle of local irritation exciting remote evils, or universal sympathy. Yet the cases of mischief have been so severe and numerous, that the practice has long fallen into great disrepute.

A transfer, however, of the mere crowns or bodies of sound teeth, with the fangs filed off, does not seem to have been productive of the same evil effects; and hence these may be conveniently made use of when the body of one or more teeth has been destroyed by caries, while the fangs have remained sound: for, by screwing a piece of gold wire into the crown of the scion tooth, and boring a hole into the fang of the lost tooth, the former may be made to take a firm hold without any attachment to the adjoining teeth; and, if due care be taken in the selection, it will make the best match, and produce the most perfect supply, that human art can bestow.

When natural teeth are not employed, the dentist has recourse to artificial teeth, commonly obtained from the tusk of the hippopotamus; though, in order to confer a greater durability, they have of late years been ingeniously formed of a composition of porcelain earth, properly modelled and burnt.

SPECIES VI.

ODONTIA INCRUSTANS.

TARTAR OF THE TEETH.

THE TEETH INCRUSTED WITH EXTRANEOUS MATTER.

THE teeth are always subject to be covered over with layers of an earthy material, secreted as a constituent part of the saliva, and denominated tartar.

Simple as this substance seems to be, no very clear explanation, either of its origin or character, has hitherto been given. According to Professor Berzelius (*Animal Chymistry*, p. 62), tartar, when it first settles on the teeth, is mere hardened mucus: "but during the destruction of the mucus," says he, "we insensibly trace phosphate of lime on the enamel of the tooth, which is sometimes increased to a crust of the thickness of from a fourth to the half of a line: and in this state it contains, besides the phosphate, about a fifth part of its weight of mucus, which has been exsiccated in the earthy mass."

Tartar of the teeth, therefore, as far as it has been analyzed, consists of concrete or dried saliva, hardened by its own earthy materials. As it flows from the salivary ducts, it is always found most accumulated around those teeth which are situated nearest to their openings. In some persons the saliva is more loaded with earthy materials than in others; for, while some have very little trouble in keeping their teeth from this deposite, in others it forms so copiously, that nothing, but an unremitted attention, will preserve their teeth from being covered with it.

While this material continues soft, it has a yellowish appearance; but, as it hardens, it changes to a dark brown or a black; and often, in children, to a dark green. By degrees the teeth lose all their beauty to the eye, the gums are detached from their respective necks, are irritated and inflamed; the alveolar processes of the teeth are exposed, absorption takes place, and the teeth become loosened; while the breath is loaded with a disagreeable fetor, from the decomposition of such a mass of animal matter. In some cases the accumulation has been so enormous, as to be half an inch in thickness, both on the outside and inside of the teeth (*Berdmore*, p. 56), or to cover the whole range of teeth, and unite them into a solid heap.—(*Eustachius*, *Tract. de Dentibus*, cap. xxix. *Stoeler*, *Beobachtungen*, &c., N. 3.)

It is almost superfluous to point out the necessity of attention to prevent so foul a disfigurement. The daily use of a tooth-brush with any of the ordinary tooth-powders, will in most cases be sufficient for this purpose. The basis of these powders is of little importance, provided they contain nothing that may injure the enamel. Pulverized fish-shells, cuttle-fish-bone, boles, bark, myrrh, mastic, soot, and charcoal, may be used with equal advantage, according to the fancy; and when an odour is wished for, it may be obtained from ambergris or orris-root. It is only necessary to observe that the powder be innocent in its quality, and impalpable in its reduction.

If the tartar yield not to these means, the milder acids may be applied. I have already observed, that there are but four known acids for which the lime of the teeth has a stronger attraction than for the phosphoric, with which it is combined; and these four are, the oxalic, sulphuric, tartaric, and succinic. From these, therefore, we ought sedulously to abstain; but most of the rest may be used very harmlessly, and will often be found, by the friction of a tooth-brush, to dissolve the tartar of the teeth without making the least impression upon their substance.*

But if the deposite still bid defiance to our

* In recommending the use of the milder acids, the author has not duly considered their effect upon the carbonate and fluat of lime, which enter into the composition of the bone, and still more freely into that of the enamel, of the teeth. Were the teeth composed entirely of phosphate of lime, then certainly the weak acids could do no harm; but as the fact is otherwise, their use is far from being commendable. Two of the acids most fre-

quently employed in medicine, are seriously destructive of the teeth, though not enumerated in the author's list of those which are calculated to decompose the teeth. When a tooth is steeped in diluted muriatic acid its earthy matter is dissolved, and the animal substance, with which it was united, left in a flexible state, and of the shape of the perfect tooth. What chymist is unaware that diluted nitric acid will dissolve the enamel?—*Ed.*

exertions, it must be removed by the operation of scaling; and the gums afterward be washed with some pleasant astringent lotion.

In India, the accumulation of tartar is prevented by an application named *miscee*, which produces indeed a black jet upon the teeth, but leaves the enamel untouched, while it destroys the tartar and hardens the gums. Its ingredients are not known.

SPECIES VII.

ODONTIA EXCRESCENS.

EXCRESCENT GUMS.

THE SUBSTANCE OF THE SURROUNDING GUMS EXCRESCENT.

Not only by the concrete deposite called tartar, are the teeth occasionally incrustated and buried, but sometimes by a prurient growth of the substance of their own gums, which, from different circumstances, appears under the two following forms:

- | | |
|---------------------|------------------------|
| a Spongiosa. | Fungous, or spongy |
| Scurvy of the gums. | gums. |
| β Extuberans. | With distinct extuber- |
| Extuberant gums. | ances on the surface. |

The gums sometimes assume a soft, fungous, or spongy appearance: and this too, as Mr. Hunter has observed (*Diseases of the Teeth*, ch. iii.), in persons who are in all other respects perfectly well: and this case, though vulgarly called a scurvy of the gums, is distinctly an idiopathic affection. It may, however, be symptomatic of dyspepsy, or some other disorder of the stomach, or some equally remote organ; or the result of a morbid state of the alveoli, or teeth themselves; and, unquestionably, it may appear as a symptom of porphyria, or real scurvy, affecting the system generally.

If the craggy stump of a tooth be the source of irritation, it will be in vain to attempt a cure till the relic of the tooth be removed: and, if the socket be in fault, it will be necessary to expose and examine it. But, in all cases in which the disease originates in the gums, and depends upon a lax state of their texture, scarification, freely and repeatedly made use of, will be the best, and, in many instances, the only remedy. It discharges the overloaded vessels, and leads both to immediate ease and a radical cure. I have frequently found it necessary to follow up the scarification into the roof of the mouth, which often partakes of the irritation, and is puckered into wrinkles of exquisite tenderness, that cannot endure the slightest touch. After scarification, the gums and mouth should be washed with some warm and resinous tincture, as that of bark and myrrh; and be gradually accustomed to the friction of a tooth-brush,

quently employed in medicine, are seriously destructive of the teeth, though not enumerated in the author's list of those which are calculated to decompose the teeth. When a tooth is steeped in diluted muriatic acid its earthy matter is dissolved, and the animal substance, with which it was united, left in a flexible state, and of the shape of the perfect tooth. What chymist is unaware that diluted nitric acid will dissolve the enamel?—*Ed.*

and some astringent tooth-powder, in the choice of which the patient may be allowed to please his own fancy; though, perhaps, the best are those prepared from several of the more astringent funguses, and especially the *cynomorion coccineum* of Linnæus, better known by the name of *fungus Mellitenensis*. And, if this plan be not sufficiently stimulant, it will be necessary to wash the mouth and gums with a very dilute solution of nitrate of silver; or to apply it, with a pencil-brush, to the gums alone in a much stronger state. Dr. Paris recommends as a dentifrice, equal parts of powdered catechu and bark, with one fourth the quantity of powdered myrrh.

The extuberant excrescence, which forms our second variety, is sometimes firm and unyielding, rising into distinct and hardened knobs, instead of assuming the appearance of soft and spongy germinations. In these cases, the general texture and consistence is that of the gums themselves: and the only radical cure consists in extirpating them with the knife, a ligature, or caustic. Even after extirpation, they are very liable to grow again, and with great obstinacy and perseverance. Mr. Hunter mentions a case, in which they were reproduced six times, as he suspected, from a cancerous disposition. They are also, in general, largely supplied with bloodvessels, which often produce a troublesome hemorrhage after the operation; [for, as Mr. Hunter observes (*Natural Hist. of the Teeth*, p. 170, 3d edit.), arteries, going to increased parts, are themselves increased, and, becoming diseased, have not the contractile power of a sound artery.]

Excrescences from the gums sometimes have so cancerous an appearance, that surgeons are fearful of meddling with them. Here a remark made by Mr. Hunter, is extremely valuable to the practitioner; namely, that when the swellings arise at once from the gum, which appears to be the only diseased part, they have no malignant disposition. When, however, there is strong evidence of a tumour having originated deeply in the alveoli, the teeth, perfect as they may be in appearance, must be sacrificed, as well as the alveolar process itself. The worst diseases of the gums, as Mr. C. Bell has remarked, do not proceed from the irritation of bad teeth. We frequently see, indeed, a carious tooth attended with ulcer and gumbile, abscess of the jaw, fungous tumour of the gums, and even necrosis of the bone. We find the pain of the inflammation equal to that of tic douloureux: but the case is not to be compared, in point of danger, with the tumour, which has a deeper source, and is frequently seen growing up beneath sound teeth. The hemorrhage that follows its removal may generally be stopped with a dossil of lint, dipped in muriated tincture of iron, and pressed into the bottom of the wound.*

There cannot be a doubt, that many cases on record, which are described as malignant

diseases of the gums, and as having proved fatal, by extending themselves up to the base of the brain, were, in fact, fungous diseases of the antrum.*]

GENUS II. PTYALISMUS. PTYALISM.

INVOLUNTARY FLOW OF SALIVA FROM THE MOUTH.

THE saliva issues from three distinct sets of glands, distributed over different parts of the mouth, as the parotid, the submaxillary, and the sublingual; [and, according to Berzelius, a quantity of it equal to 1000, consists of water 992.9; a peculiar animal matter 2.9; mucus 1.4; alkaline muriates 1.7; lactate of soda and animal matter 0.9; pure soda 0.2.—(*Med. Chir. Trans.*, vol. iii., p. 242.)] What Berzelius sets down as mucus, is considered by Professor Thomson and Dr. Bostock to be albumen. This is insoluble in water, and, when incinerated, affords a large portion of phosphate of lime. The tartar of the teeth is derived from its gradual decomposition upon them. The recent investigations of Tiedemann and Gmelin, however, to which reference has been made in the physiological proem, prove saliva to be a more compound fluid than was formerly supposed; and one of their principal discoveries is, that the sulpho-cyanic acid, a most active poison, combined with potass, enters into its composition. Its solid contents are found to be, according to some chymists, 7 in 1000 parts, but, according to others, 1.25 per cent. The quantity of saliva secreted daily is considerable. Nuck and Lanzoni estimated it at a pound in twelve hours; Mr. Cruickshank at a pound in twenty-four hours; but it must vary according to circumstances. The secretion is more copious in children and old persons, than in adults; in cold, than in warm climates; in the day, than in the night. The smell or sight of any agreeable food makes the saliva flow into the mouth with surprising rapidity. The same effect results from the irritation of smoking tobacco; and from that of bitter, sour, or salt substances in the mouth. The habit of frequently ejecting spittle from the mouth renders an augmented secretion of it necessary. A person's talking much has a similar consequence; and so large is the quantity of saliva secreted during meals, that Sabatier saw a soldier, who, at these periods, used to wet several towels with what was discharged from a fistula communicating with the parotid duct.† In disease, the secretion

* For examples of the fatal ravages of some diseases of the gums, consult J. Bell's *Principles of Surgery*, vol. iii.; C. Bell's *Quarterly Report*, vol. i.; Hill, in *Edinb. Med. and Surg. Journ.*, No. 61; and Gibson, in *Philadelphia Journ.*, vol. ii.

† *Traité d'Anat.*, tom. ii., p. 171. Dr. C. G. Mitscherlich, of Berlin, lately met with a similar case, in which the more solid and grateful the nature of the food was, the more copiously was the secretion of saliva carried on; but when the masseters and tongue were at rest, and no stimulus

* See C. Bell's *Surgical Obs.*, vol. i., p. 413, &c., and Gibson's *Institutes of Surgery*, vol. ii., p. 323.

of saliva is sometimes increased; sometimes, almost suppressed.] Its office is twofold: that of moistening the mouth in combination with a small portion of mucus secreted by the labial and buccal glands, and that of contributing to the digestion of the food in the stomach and duodenum.

Under the influence of the irritating passions, and especially of violent rage, it assumes a frothy appearance, and in many animals becomes poisonous. It is said, indeed, to become so sometimes in man himself.*

When the saliva is secreted in a healthy proportion, and the various muscles of the mouth perform their proper office, it is never discharged from the mouth, unless voluntarily; but passes readily from the fauces into the œsophagus. But it may be secreted immoderately, or the muscles of deglutition may not properly perform their functions: and, in either case, the saliva will flow from the mouth involuntarily, accompanied with a specific difference of symptoms. And hence ptyalism, as a genus, offers the two following species of disease.

1. Ptyalismus Acutus. Salivation.
2. ————— Iners. Drivelling.

SPECIES I.

PTYALISMUS ACUTUS.

SALIVATION.

INCREASED SECRETION OF SALIVA FROM AN INCREASED ACTION OF THE SALIVARY GLANDS.

AN increased action of the salivary glands, productive of salivation, occurs not unfrequently as a symptom of some other disorder; and a symptom that in many cases proves highly salutary, and even critical: as in fevers of various kinds, exanthems, of which Dr. Perceval of Dublin writes me word, he has had instances in miliaria with transparent vesicles, in jaundice, and dropsy; and other examples of which are given in the author's Nosology. It often takes place also in suppressed discharges of various kinds, as those of menstruation, perspiration, and urine, and is occasionally found a useful substitute. But as in all these cases it is a mere concomitant or dependant affection, we must defer our consideration of it in these relations, till we come to the diseases themselves, of which it is a symptom or sequel.

The salivary glands are directly excited to an increased action by stimulants, or sialagogues, as they are called, of various kinds. There are numerous plants endowed with this power, which in their roots, bark, or leaves, contain a warm, acrid juice: as tobacco, mezereon, pyrethrum, or pellitory of Spain; *pimpinella saxifraga*, or smaller burnet saxifrage; imperatoria, or masterwort. Simple mechanical pressure, produced by the manducation of any hard substance, as when we eat a dry biscuit, is also a stimulant

of the same kind; far less active indeed, but highly useful in its effect, as tending to resolve the substance to which the pressure is applied. Dentition is a common cause, at whatever time the teeth be produced. Even the mechanical irritation of another organ, with which the salivary glands are closely connected by continuity or sympathy, will often lead to a like effect. Mr. Powell has given an interesting instance of this in vol. ii. of the Medical Trans. of the College. A piece of wool, accustomed to be worn in the ear, had imperceptibly slid into the meatus auditorius, and for upwards of two years stimulated the organ without being suspected; during the whole of which period the patient discharged from a pint to a pint and a half of saliva daily. The ear itself at this time became painful, and was examined; the piece of wool was detected, and extracted in a very offensive state; and the salivation in a short time entirely subsided. In like manner, it is a frequent accompaniment of pregnancy; as it is occasionally of some other irritation of the stomach or intestinal canal; in which last case it frequently betrays its source by a saccharine taste. [In some cases, the cause is obscure. The editor knows a gentleman, who had several annual and tedious attacks of a very debilitating ptyalism, the reason of which was by no means apparent from any particularity in the previous state of his health, or in his regimen; and M. Ribes mentions a porter at the hospital for invalid soldiers at Paris, who was annoyed for six weeks with a salivation, that used to increase in such a degree at night, that the flow of saliva from the mouth might have been compared to a shower of very clear water.* No cause could be assigned for the complaint.]

Generally speaking, however, though not always, an increased flow of saliva from any of the above causes is of such short duration, and so easily removed when troublesome, that it is rarely the subject of medical attention; and the only varieties to which it gives rise, that are particularly worthy of notice, are the following:

- | | |
|-----------------------|--------------------------------------|
| α Hydrargyratus. | Produced by the use of |
| Mercurial salivation. | mercury or its preparations. |
| β Sensitivus. | Produced by the sight, |
| Mouth-watering. | smell, or thought of agreeable food. |
| γ Mellitus. | Accompanied with a |
| Sweet-spittle. | sweet or mucilaginous taste. |

was present, it ceased altogether. During meals, he found the saliva alkaline; at other periods, acid.—ED.

* Hoffman, Diss. de Salivâ ejusque Morbis, p. 24.

* See Dict. des Sciences Méd., tom. xlix., p. 459. M. Andral could detect no morbid appearances in the salivary glands of a man, who had had a ptyalism of long duration from no evident cause.—Anat. Pathol., tom. i., p. 345. M. Rayer relates the case of a woman, aged 24, who for many years, without any obvious cause, had an attack of profuse salivation every month or six weeks. The complaint generally continued 36 or 48 hours, the quantity of fluid excreted amounting to several pints in the course of 24 hours. Opium and quinine had no effect in relieving the disorder, but it was finally cured by the subcarbonate of iron.—(Journ. de Chimie Méd., Avril, 1833.)

Quicksilver, in whatever mode introduced into the system, whether by the skin, the stomach, or the lungs, uniformly stimulates the salivary glands, and produces an increased flow of saliva: and is almost, if not altogether, the only substance we know of, which, introduced internally, universally acts in this manner. Nitric and other acids have been suspected to produce a like operation.

[The author of this work and Dr. Paris, however, both consider the opinion groundless. Yet, according to the evidence of Dr. Scott, if the nitro-muriatic acid, lotion, or bath, be employed to a certain extent, tenderness in the palate and mouth, and pytalism, are sometimes produced; but without any offensive smell of the breath or loosening of the teeth, as from mercury. These effects were excited in himself and others, and he had seen as violent a salivation thus raised, as he had ever noticed from mercury.]—(*Med. Chir. Trans.*, vol. viii., p. 183, and *Beddoe's Contributions*, p. 430.)

Antimony has also been thought by a few practitioners to have some such influence upon the salivary glands. "Dr. James lately informed me," says Sir George Baker (*Medical Transactions of the College*, vol. i., p. 378), "that for sixteen years past his fever powder has contained no mercury; and yet, that within that space of time, he has known at least six instances of a salivation raised by his medicine. He added, that the patients who were thus salivated had neither their teeth loosened, nor their breath made offensive, as happens in a mercurial pytalism." Fusch tells us (*Dissert. de Antichiria, Jen.*, 1681), that he has occasionally observed a like effect; as does Willich, when tartarized antimony has been employed.—(*Baldinger, N. Magazin.*, band viii., p. 252.)—[According to Dr. Paris (*Pharmacologie*, vol. i., p. 238, 6th edit.), the latter medicine in nauseating doses certainly promotes a salivation by mercury; and so does the accidental superintention of any disease of debility. The editor has seen in the King's Bench and Fleet prisons, four or five cases in which an annoying degree of salivation proceeded from the free use of the compound squill pill. A similar fact is recorded by Quarim.]—(*Animadversiones Pract.*, Viennæ, 1786.)*

From the general tendency of mercury to produce this specific effect, those who are engaged in working quicksilver mines, as those of Idria or New Spain, are almost continually in a state of salivation: and when, which is often the case, condemned as criminals to such labour for life, drag on a miserable existence, in extreme debility and emaciation, with stiff, incurvated limbs, total loss of teeth, and equal loss of appetite, till death in a few years, with a friendly stroke, puts a period to their sufferings.†

* The list of medicinal agents capable of inducing salivation might easily be increased by adding to those mentioned in the text, squills, iodine, and the oxy muriate of gold. We have seen excessive pytalism produced also by an emetic of sulphate of zinc.—D.

† "Emaciation is the constant attendant of a

From the facility with which quicksilver evaporates, and combines, not only with other metals, but with almost all other substances, and especially with many of the elastic gases, a considerable degree of injury is often sustained by workmen in manufactories, in which quicksilver is occasionally employed, without their being for a long time aware of the cause. An instance of a similar kind occurred on board the Triumph man-of-war, which had received on board thirty tons of quicksilver, contained in leathern bags of fifty pounds each, that had been picked up on the shore at Cadiz from the wreck of two Spanish line-of-battle ships, that had been lost during a storm in March, 1810. The bags were stowed in the hold, and other low parts of the ship; but being saturated with seawater, they soon decayed and burst. The quicksilver, thus let loose, was collected as well as it could be, and committed to proper casks: but much of it escaped into the recesses of the ship; and not a little was secreted by the sailors, who amused themselves with it in various ways. The quicksilver that had escaped unnoticed sunk into the bilge-water, became partially decomposed, and ascending soon after, amidst an intolerable stench, with the vapour of the water, coated every metallic substance in the ship with a black hue; and at the same time a general affection of the mouth took place among the men and officers, to such an extent, that no less than two hundred became severely salivated, and did not recover till the ship, being carried into Gibraltar, was docked and cleaned to its lowest planks.

Mercury, however, produces different degrees of effect upon different constitutions or states of the body. In a few rare instances, it has exerted no sensible influence whatever upon the excretories of the fauces: in others, a very small quantity of almost any of its preparations has stimulated them at once to a copious discharge.

In persons of a highly nervous or irritable temperament, I have known salivation produced by a single dose of calomel; and that it is sometimes caused by dressing ulcers with red precipitate, is a fact mentioned by Hildanus, and well known to all experienced surgeons. In scorbutic, scrofulous, and other debilitated habits, very small quantities of mercury will sometimes act in the same manner; and hence a considerable degree of caution is requisite in all cases of this kind. Even the wearing of a leathern girdle, or the occasional application of white precipitate or mercurial ointment to the head to destroy vermin, has often excited salivation.

mercurial course. In producing their effects, mercurial preparations, whether oxides, chlorides, cyanides, iodides, or any other, are decomposed, and the mercury, in a metallic form, is either thrown out of the body by the skin and lungs, or deposited in the glands and bones." In Hufeland's Journal it is stated, that a pelvis, infiltrated with mercury, and taken from a young woman who died of syphilis, is preserved in the Lubben Museum of Midwifery.—See Thomson's Elem. of Materia Med., t. i., p. 370—372.

When mercurial salivation is produced, it is accompanied with a high degree of irritation, not only of the mouth and fauces, but of the system generally. The common course of symptoms is as follows: the mouth feels unusually hot, and is sensible of a coppery or metallic taste; the lingual and sublingual glands swell; aphthous vesicles appear, and terminate in minute and offensive ulcerations; the tongue tumefies; the throat becomes sore; pyrexia and sleeplessness supervene, and are, indeed, often present from an early period of the disease; while in idiosyncrasies, or habits of great irritability, we frequently find the surface of the body wholly, or in particular parts, reddened with a peculiar erythematic inflammation, continuous or in patches, to which the name of hydrargyria has been given by some writers, and that of *erythema mercuriale* by others. [Gangrene and necrosis may be the consequences of immoderate mercurial salivation. Large sloughs of the parts in the mouth are very common. Cullerier has seen a partial necrosis of the lower jaw produced in this manner, and, in one young woman, a complete necrosis of the upper and lower alveolar arches.—(*Dict. des Sciences Méd.*, tom. xlix., p. 455.) The editor of this work has witnessed several melancholy examples of the same kind.]

It is difficult to determine by what means mercury produces its effect on the salivary glands. Dr. Cullen attempted one explanation of the subject; namely, that "mercury has a particular disposition to unite with ammoniacal salts, and that such salts are disposed to pass off by the salivary glands more copiously, than by any other excretion." But, as Dr. Murray has remarked, mercury has not any peculiar tendency of this kind. Indeed, if it had, no ammoniacal salts are mentioned, either by Berzelius, or by Tiedemann and Gmelin, as entering into the composition of the saliva. Dr. Cullen regards mercury as nothing more than a general irritant, operating equally upon all the sensible and moving fibres of the body, and hence powerfully operating upon all the excretories of the system, without having a special affinity to one set more than to another. "It proves often," says he, "diuretic; and I have particular proofs of its reaching and acting upon the organs of perspiration."* Another hypothesis is that of

Sir Gilbert Blane,* who considers the salivary glands as one of the outlets for the ramenta of the bones, because lime is detected in the saliva, and even concretes on the teeth. Now, as mercury is known to produce an active absorption of the solids, it is ingeniously conceived, that the fact in some measure explains its effect upon the salivary glands. However, as the kidneys and other excretory glands also furnish outlets for the old particles of the body, and yet are not affected by mercury in the same degree as the salivary glands, this theory cannot be retained. The fact, however, remains the same, namely, that mercury, whether it possess a specific affinity or not for the excretories of the saliva, acts, from some cause or other, more readily and powerfully upon them than upon any other excretories whatever.

In attempting a cure of salivation from mercury, our attention is to be directed to the local state of the fauces, and the general state of the system.

If the throat be not much inflamed, acidulous gargles and acerb fruits, as the sloe, may be employed with great advantage, and should be used freely; but if there be considerable irritation, we must at first content ourselves with emollient gargles of barley-water or quince-seeds:† and in either case employ, at the same time, purgatives of Epsom or other neutral salts. When the system is much affected, sulphur and opium have been strongly recommended, and seem in many cases to have been successful. The former is trusted to, chiefly from its being well known to diminish the activity of mercury out of the body;—a doubtful reason, however, for our employing it internally.‡ The latter is certainly of considerable use in allaying the general restlessness and irritation of the system. The free exposure of the patient to a cool pure air, was found by the late Mr. John Pearson to be one of the most decided means of checking profuse salivation. The diet should be of milk. It may also be added, that perhaps there is no disease in which the Lisbon diet-drink, or compound decoction of sarsaparilla, may be used with better effect. Taken in the quantity of a quart a day, it carries off the effects of the poison, and supports the system.§

nevertheless taken into the circulation, for they communicate a blue appearance to silver articles in the patients' pockets." *Elem. of Materia Med.*, vol. i., p. 371.

* *Trans. for the Improvement of Med. Knowledge*, vol. iii., p. 112.

† As a gargle, Dr. Thomson recommends alcohol or brandy and water, or the chloro-sodaic solution of Labarraque in water, in the proportion of one part of the solution to four of water. Vol. cit. p. 375.

‡ It is remarked by Professor A. T. Thomson, that the experience of those who have had the best opportunities of judging, has not satisfied them that it possesses any efficacy in diminishing mercurial action. He adds, that if preparations of sulphur have at any time proved beneficial in checking salivation, the effect is to be referred to their acting either as sudorifics or purgatives.—*Elem. of Materia Med.*, vol. i., p. 375.

§ Dr. Falmestock states (*Amer. Jour. of Med. Sciences*, vol. v., p. 62), that in cases of salivation

* *Mat. Med.*, vol. ii., p. 443. Professor A. T. Thomson entertains a similar view:—"Mercury," says he, "in whatever form it is administered, and in whatever manner it is introduced into the living body, acts as an excitant; a febrile state of the body is induced, evidenced both by the condition of the pulse, and that of the nervous system; and also by an augmented secretion and excretion of the saliva. It is this febrile excitement, overcoming or destroying the morbid action begun and maintained in the frame by the introduction of the syphilitic or venereal poison into it, which cures syphilis. The action on the salivary glands is only a symptom of this general excitement, induced by mercurials, and not in itself essential to their curative power: it may not be produced by the administration of mercurials, and yet syphilis may be cured by them. In this case the mercurials are

[Some cases of inordinate salivation, recorded by Dr. Haskins, tend to prove that emetics have considerable power in relieving the disorder.*]

Like most other poisons, mercury, when properly directed, may be rendered a most valuable medicine; and is at this moment, in its multifarious forms, one of the most common, as well as one of the most efficacious, in the *Materia Medica*. In this place, however, we can only contemplate it as a source of disease.

A certain degree of active pytalism is also well known to be produced by any high degree of mental or sensorial excitement; in which case, the discharge most commonly assumes a frothy appearance. This is particularly the case with violent rage, which stimulates the salivary glands almost as much as grief does the lachrymal. And as the same muscles of the mouth and throat are strongly roused in epilepsy and lyssa, we have here also a like increase of saliva, worked into the same sort of foam, and accompanied with a similar biting of the lips and gnashing of the teeth. But the most striking proof of this effect is produced by an eager longing for agreeable food of any kind, whether seen, smelt, or only thought of; and which is vulgarly denominated MOUTH-WATERING.

In man, this increase of secretion is seldom so considerable as to occasion an involuntary flow from the mouth; but, in dogs, it flows freely and continuously; for here the salivary glands are peculiarly irritable, so that the animal is almost constantly salivating; the discharge appearing to answer the purpose of insensible perspiration in other quadrupeds.

We meet also occasionally with an increased secretion of saliva from a cause less obvious, distinguished by a sweet or mawkish taste;† to which some writers have given the name of SWEET-SPITTLE.‡ It is the *dulcedo sputorum* of Professor Frank.§ It may possibly exist, at times, as an idiopathic complaint, but is more usually connected with a morbid state of the stomach, and accompanied with a sense of nausea; the saccharine matter being formed, perhaps, by a like assimilating power as that possessed by the kidneys in diabetes. It is relieved by magnesia, and other absorbents; but is most

from mercury, he has used, "with uniform and unparalleled success," a gargle made from the inner bark of the root of the *rhus glabrum*. Professor Geddings, of Baltimore, has given the *oleum terebinth* with the most satisfactory results. He generally prescribes two drachms of the turpentine, mixed with eight ounces of gumarabic mucilage, to be used frequently as a gargle. He has also employed the undiluted turpentine, and with success.—(See *Amer. Jour. of Med. Scien.*, vol. vii., p. 267.) Dr. Francis informs me that he has seen good effects resulting from pulverized charcoal, taken internally and at short intervals. In a late German periodical, Hufeland speaks highly in favour of iodine.—D.

effectually cured by an emetic, followed by warm stomachics. A lady of delicate habit, under my care, has been subject to this variety for some years. It returns irregularly, for the most part once in about a month or six weeks, and generally yields to a course of rhubarb, taken sometimes in conjunction with two or three grains of calomel. Bloch (*Bemerkungen*, p. 203) mentions a case, in which it returned at periods still more regular. This variety of pytalism is also occasionally the result of a scorbutic diathesis, but more frequently of phthisis; and especially in the last stage, when, as Frank observes, it is often "insignis et ad nauseam usque molesta."

A pytalism frequently occurs during dentition; and is by no means an uncommon sequel or crisis of other diseases.

In all these, as I have already hinted, it proves salutary, and terminates the disorder that excites it. Fevers afford, perhaps, the most numerous examples of this; and the following case is worth relating: A lady, aged twenty-four, of a delicate constitution, was attacked with a typhus, in the spring of 1788, which ran on for three weeks. She appeared to be in great danger; but on the twentieth day, a sudden and copious salivation took place, that unaccountably afforded her great relief. It continued for upwards of a week, the daily flow from the mouth being never less than a pint and a quarter. In the meanwhile, she increased in strength, recovered her appetite, and got well.

We have numerous instances, in which this discharge has proved equally serviceable, about the acme of smallpox;* though in one or two cases death has succeeded.† The fluid of dropsies is said to have been carried off at times by the same channel.

In the *Medical Obs. and Inquiries*, vol. iii., p. 241, there is a singular case of an obstinate vomiting of five months' standing, being relieved upon a return of salivation, which for this period had ceased. But perhaps one of the most extraordinary instances to be met with is related by Dr. Huxham, in the *Phil. Trans.*, vol. xxxiii., for 1724. The patient was a man aged forty, of a spare, bilious habit, who had an attack of jaundice, followed by a paroxysm of cholice, this last being produced by drinking too freely of cider. Among other medicines was given a bolus, containing a scruple of jalap, eight grains of calomel, and a grain of opium. Copious dejections followed; and a few hours afterward the patient complained of pain and swelling in the fauces, spit up a little thick brown saliva, which was soon considerably increased in quantity, of a deep colour, resembling greenish bile, though somewhat thinner. This flux of green and bilious saliva continued for about forty hours; during which time the quantity discharged amounted to four pints. The colour

* *Act. Nat. Cur.*, vol. vii., Obs. 109. Fich, *Diss. de Salivatione spontaneâ, præcipuè Variolarum*. Jen. 1713.

† Riedlin, *Lin. Med.*, 1695, p. 384. Weber, *Obs. Med. Fascic. i.*

of the saliva then changed to yellow, like a solution of gamboge, with an increase rather than a diminution of the quantity. It continued of this colour for the space of forty hours more, after which it gradually became pellucid, and the salivation ceased as suddenly as it came on. During the flow of the saliva, the teeth and fauces were as green as if they had been stained with verdigris, and the teeth retained the same colour for a fortnight after the ptyalism had ceased. The patient had a few years before been suddenly attacked by a spontaneous salivation, so excessive as to endanger his life. In the present instance, therefore, it is probable, that the dose of calomel co-operated with the peculiarity of the constitution in exciting the discharge. But whatever was its cause, it proved critical, both of the jaundice and the colic; for, from the moment it took place, the pain of the bowels ceased, and the greenish colour of the skin began to subside, the urine being at the same time secreted more abundantly, and of a blackish hue.

SPECIES II.

PTYALISMUS INERS.

DRIVELLING, OR SLAVERING.

INVOLUNTARY FLOW OF SALIVA FROM A SLUGGISHNESS OF DEGLUTITION, WITHOUT INCREASED SECRETION.

THERE is a second species, which belongs to this genus, in the present system, distinguished by the name of *inert ptyalism*, and which depends upon a want of command or power over the muscles of deglutition, rather than on any increased action of the salivary excretories. In vulgar language it is denominated *drivelling*, or *slavering*. It occurs under the three following modifications:

- | | |
|---------------|------------------------|
| α Infantilis. | Of infancy. |
| β Senilis. | Of old age. |
| γ Moria. | Of dotards, or idiots. |

It is found, therefore, in three states of life: among infants, before the will has acquired a power over the muscles of deglutition, and is altogether distinct from the salivary flux of dentition; in advanced life, in which the will has lost its power; and in idiots, who possess the power, but seldom or never exercise it. In the first case, time is the best physician; in the two last, no physician can be of any avail.

GENUS III.

DYSPHAGIA.

DYSPHAGIA.

PAIN OR OBSTRUCTION IN SWALLOWING, WITHOUT INFLAMMATION, AND MOSTLY WITHOUT IMPEDED RESPIRATION.

It is necessary to limit the character of this genus, as in the above definition, since inflammatory affections, in whatever part of the system they occur, constitute one natural order; and dyspnetic affections, or those essentially impeding the respiration, another order; and

Vol. I.—E

should, therefore, be arranged and considered in their respective associations; the former, under the diseases of the sanguineous function, and the latter, under those of the respiratory.

[Deglutition is a very complex operation, requiring the concurrence of many agents, from the mouth, where it begins, down to the cardiac orifice of the stomach, where it terminates. It may be divided into three stages: in the first, the food passes from the mouth to the pharynx; in the second, it passes the opening of the glottis, and the nasal apertures in the fauces, and is carried into the œsophagus; in the third, it passes through this tube, and enters the stomach. When a portion of food has been sufficiently chewed, it is placed by the actions of mastication upon the dorsum of the tongue. Mastication is then suspended, and the tongue applied to the roof of the mouth in succession, from its point to its base. The alimentary bolus is thus pressed towards the pharynx, and soon meets with the velum palati, which is raised up by it into the horizontal position, and made a continuation of the palate. As the tongue continues to press the food, it would push it towards the nasal openings in the fauces, if it were not for the tension of the velum palati, produced by the circumflex muscles and the constriction of the pillars. With the exception of the motions of the velum, these actions in the first stage of deglutition are slow, voluntary, few, and successive. In the second stage, the actions are simultaneous, multiplied, involuntary, and rapid; the food is conveyed by them only from the middle to the bottom of the pharynx; but quickness is essential, in order that the aliment may not insinuate itself into the glottis, impede respiration, or glide into the nasal openings in the fauces, or the apertures of the Eustachian tubes. The aliment no sooner touches the pharynx, than it is embraced by this part and the velum palati. At the same instant, the base of the tongue, the os hyoides, and the larynx, are raised and carried forward to meet the morsel of food, and transmit it rapidly over the glottis, which is now shut, and also covered by the descent of the epiglottis. By the continued pressure of the pharynx and velum palati, the food is next pushed into the œsophagus, the larynx descends, the epiglottis rises, and the glottis itself is opened again for respiration. In the third stage of deglutition, the arrival of the food in the upper part of the œsophagus causes the superior circular fibres of this canal to contract, and propel the aliment towards the stomach. The subsequent fibres, now distended, contract in their turn; and the same changes are continued in succession, until the food gets into the stomach. The experiments of Magendie convince him, that the aliment passes very slowly down the œsophagus, and, when its ready entrance into the stomach is prevented, it will sometimes rise and descend again several times before it is ejected.* From the preceding account it

* See Magendie's Physiology, by Milligan, 2d edit., p. 238.

must be manifest, that many different causes may be concerned in bringing on a difficulty of swallowing; and that dysphagia, strictly speaking, is not a disease itself, but only one of the most dangerous effects of the diseases to which the organs of deglutition, or other parts in the neighbourhood of them, are subject. The history of every form of dysphagia would make therefore a very long detail, comprising an account of most of the diseases of the mouth, throat, nasal cavities, pharynx, larynx,* and œsophagus, as well as of various accidental injuries of parts about the throat, and of many sorts of tumours within or near the mouth, the pharynx, or œsophagus.† In the present part

* Dr. Abercrombie has seen several cases of disease of the larynx in which the dysphagia was the prominent symptom, so as to lead to the supposition of disease of the œsophagus. In one instance the epiglottis was thickened and much elongated; the patient had no constant difficulty of swallowing, but was liable to sudden attacks of it during his meals, which threatened instant suffocation. In another case, the dysphagia was permanent, and combined with a hoarse, husky cough, and slight dyspœa. The whole body of the larynx was very much enlarged and thickened; and some ulceration existed in it internally towards the œsophagus. In both cases the œsophagus was entirely healthy.—See Abercrombie's *Pathol. and Pract. Researches on Diseases of the Stomach, &c.*, p. 97, ed. 2.

† Instances are recorded by Valsalva and others of dysphagia from dislocation of the os hyoides. In the *Journ. des Progrès, &c.*, t. xiv., p. 250, a case of this kind is related, which was cured by reduction. Dr. Abercrombie gives the following particulars of another example: "An eminent medical man, now deceased, was liable to this accident, and I have seen him seized with it in an instant, while engaged in conversation. It produced slight difficulty of articulation, and total inability to swallow. He easily relieved himself by a particular movement of the parts with his hand, which had become familiar to him from the frequent occurrence of the accident."—(*Pathological and Practical Researches on Diseases of the Stomach, Intestinal Canal, &c.*, p. 102, ed. 2. 1830.) See another case in *Med. Gazette*, vol. iv., originally reported by Dr. Mugna in the *Annali Universali*. Sir Charles Bell had a preparation, exhibiting a projection of one of the horns of the os hyoides into the pharynx in consequence of ulceration.—(*Surgical Obs.*, p. 60.) Bleuland gives the particulars of a dysphagia produced by the pressure of an exostosis of the vertebra upon the œsophagus. Sir Astley Cooper reports an example, in which the same consequence arose from a dislocation of the sternal end of the clavicle backward. Aneurism of the aorta frequently causes dysphagia, which may exist long before the original disease is suspected. Dr. Abercrombie refers to a case in which a probang was passed, under the idea of stricture of the œsophagus; it occasioned rupture of the aneurism, and almost immediate death.—(*Op. cit.*, p. 100.) Among numerous other circumstances which may occasion dysphagia by pressure on the œsophagus, I may mention enlargement of the thyroid gland, bronchial glands, or glands in the posterior mediastinum; great distention of the pericardium.—(*Bleuland de sana et morbosa Cœsophagi Structura*.) I dismiss from present consideration dysphagia from congenital malformations and imperfections of

of this work, the author enters into the consideration of the six following species:—]

1. Dysphagia Constricta. Constrictive Dysphagia.
2. ——— Atonica. Atonic Dysphagia.
3. ——— Globosa. Spasmodic dysphagia, or Nervous Quinsy.
4. ——— Uvulosa. Uvular Dysphagia.
5. ——— Lingua. Lingual Dysphagia.
6. ——— Pharyngea. Pharyngeal Dysphagia.

[The several cases of dysphagia arising from a diminution of the capacity of the œsophagus by disease of its texture, or from its being occupied or compressed by tumours of different sorts, are at first so similar in their symptoms and progress, that a successful discrimination of them is not always easy. In all of them, one of the earliest symptoms is a difficulty of swallowing solids, followed, after a time, by that of swallowing fluids. This inconvenience makes more or less rapid advance, and if not relieved by medical treatment (which is too often impracticable), terminates in a fatal interruption of the function of deglutition. With the exception of spasmodic dysphagia, and cases of mechanical injuries of the jaw and parts about the mouth and throat, almost all the species of dysphagia come on very gradually, and with so little annoyance that at first they are apt to be disregarded, more especially as the health is generally good, and the inconvenience in swallowing sometimes abates for a time, or even quite ceases. Nor in general can any defect be seen or felt in the mouth or pharynx; the food passes the isthmus of the fauces very well, and proceeds duly towards the stomach; but it soon rises into the mouth again, with a large quantity of saliva, unaccompanied by any effort of the stomach, diaphragm, and abdominal muscles. The patient again tries to swallow, and, perhaps, after repeated attempts, succeeds in getting the food into the stomach, in small quantities at a time. Thus the disease is allowed to go on unresisted for a long period. The kind of rumination resulting from the inverted peristaltic action of the œsophagus, differs from common vomiting, inasmuch as the food is ejected without anxiety, indisposition, or cold sweats. Notwithstanding the difficulty of swallowing, the appetite often continues good, almost until the very approach of death.]

SPECIES I.

DYSPHAGIA CONSTRICTA.

CONSTRICTIVE DYSPHAGIA.

DIFFICULTY OF SWALLOWING, FROM A PERMANENT CONTRACTION OF THE CŒSOPHAGUS.

SOMETIMES the diameter of the canal is diminished in particular parts by a thickening of the mucous membrane, fleshy excrescences, or fungous,* or scirrhous tumours. The same

the pharynx, œsophagus, palate, &c. Sir Astley Cooper reports the case of an infant which, though born without an œsophagus, lived eight days.—*Ed.*

* In Dr. Armstrong's *Morbid Anatomy of the*

effect may proceed from tumours formed between the coats of the œsophagus.—(*C. Bell's Surg. Obs.*, p. 60.) Sometimes a scirrhus thickening of its coats, or of the cellular membrane connecting them,* extends through its entire length; and sometimes it becomes contracted by the conversion of a portion of it into cartilage or bone. Besides these cases, there are other casual and symptomatic obstructions, which do not fall under our present survey, produced by hysteria and other spasmodic affections; by enthesis, or the lodgment of foreign bodies in the canal; or external tumours, as in bronchocele, abscesses,† or aneurism of the aorta, pressing against its sides.

[The œsophagus is much less frequently the seat of disease than the mouth and the pharynx, and especially than the stomach and other parts of the digestive tube, below the diaphragm.—(*Andral, Anat. Pathol.*, t. ii., p. 244.) Its lining, like all other mucous membranes, is liable to be thickened by inflammation; the diameter of the passage is thereby lessened; the muscular fibres cannot act upon it with their usual power; and the conveyance of the food into the stomach is more or less obstructed. True strictures of the œsophagus, like those of the urethra, generally occupy but a small extent of the canal, and are for a long time attended with very little thickening of the adjacent parts. The derangement is in the inner membrane of the tube; there is no apparent disease of the tunica vaginalis gulæ; nor any degree of thickening of the glandular structure.—(*C. Bell, Surgical Obs.*, p. 80.)

Stomach, &c. (Plate 8), may be seen a representation of a stricture occasioned by the cardia being surrounded by a tumour, that had the character of fungus hæmatodes, or, as he terms it, fungus encephaloides. The same author had seen another similar case; and both proved fatal before any degree of softening took place in the morbid substance. No similar formations were found in other parts.—EDITOR.

* See Armstrong's *Morbid Anat.*, fasciculus 2; pl. 7, fig. 2.

† Mr. Carmichael has recorded two fatal examples of dysphagia, from abscess between the œsophagus and cervical vertebra, where, from the situation and circumstances of the disease, as found on dissection, he conceives that the patients' lives might have been saved, had the collection of matter been discharged with a curved trocar.—See *Trans. of Association of Physicians of Ireland*, vol. iii., p. 170, &c. "A remarkable case occurred to Mr. George Bell, in which the dysphagia had existed so long that it was considered as an example of stricture of the œsophagus, and a probang was introduced. When this reached the part, which was very low down, it ruptured the abscess, and an immense discharge of matter took place, with immediate and permanent relief."—(*Abercrombie's Pathol. and Pract. Researches on the Stomach*, &c., p. 99.) The same author quotes from Bleuland a case of fatal dysphagia from abscess between the vertebra and upper part of the œsophagus. Collections of matter in the lungs may also press upon this tube, and ultimately form a communication with it; examples of which are referred to in Dr. Abercrombie's work, on the authority of Bleuland and Künze (*De Dysphagia*).—EDITOR.

Strictures may occur in any portion of the tube; but their most frequent situation is immediately behind the cricoid cartilage at the termination of the pharynx. Sometimes the pharynx and beginning of the œsophagus are studded with scirrhus tumours of great firmness and whiteness, nearly closing the latter canal; while a general disposition to disease of its membrane is denoted by tumours of a similar nature lower down the passage. At the same time, the membrane, reflected over the glottis into the trachea, may be thickened, and even swellings of the above description present themselves within the latter organ. Another form of scirrhus of the œsophagus is very analogous to the disease called the scirrho-contracted rectum; it involves all the coats of the tube, and though it may affect the greater part of the passage, it generally commences either in the upper portion of it behind the cricoid cartilage, or far down near the cardia, where the structure is very glandular.—(*Monro's Morbid Anat. of the Gullet*, &c., p. 325.) Scirrhus changes the texture of the œsophagus sometimes into a hard, uniformly fleshy substance, and sometimes into a substance of a gristly nature, or intersected by membrans.—(*Baillie's Works*, by Wardrop, vol. ii., p. 93.) Under such circumstances, the canal is always rendered narrower, and often nearly closed. The disease is also frequently complicated with ulceration, which is mostly seen either above or below the most constricted point, not exactly in it. A fact meriting attention is, that obstructions situated high up in the œsophagus, frequently give rise to ulceration of the lower part of it, near the stomach, just as strictures in the urethra often produce ulceration of that canal towards the bladder. In the œsophagus, this kind of ulceration is most liable to occur when the obstruction has existed a long time; and the frequent retching is conjectured to be the occasion of it. Though ulceration does not generally attack the most constricted portion of the tube, it does so in particular examples, just as it does in the urethra, and this in such a manner that the obstruction is more or less removed. Relief only follows this event, however, in cases of common stricture of the mucous membrane; for when the disease is of a scirrhus nature, ulceration always proves an aggravation of the complaint, instead of a possible means of relief. Indeed, when the œsophagus has been rendered even more capacious than natural by the effects of scirrhus ulceration, the continuity of the muscular action, by which the food is transmitted to the stomach, is interrupted, and a disease, very different from stricture, resembles it in its most essential circumstance, the incapacity of swallowing.* By ulceration of the œsophagus, prternatural communications may be formed between that

* Sir C. Bell, in *Surg. Obs.*, p. 62. According to Dr. Armstrong, when a softening of the scirrhus matter takes place, the muscular coat may suffer in the destructive process, and be attenuated.—(*Morbid Anat.*, &c., p. 54.) He adds, that, in general, it seems thickened, owing to the cellular texture connecting its fibres being in this state.

tube and the trachea,* lungs,† or aorta. The latter state may also be the result of disease itself.—(*Meckel's Anat.*, vol. iii., p. 254.) Here also the remarkable case of Admiral Wassenaer deserves to be mentioned, who, according to Boërhaave, died suddenly in the act of attempting to vomit soon after dinner, and whose œsophagus was found to have given way in the seat of an ulcer, so that all the food and drink taken at dinner had become effused in the cavity of the chest. A similar case, in which the œsophagus was perforated near the cardia, and the contents of the stomach, together with a lumbricus worm four inches in length, were effused in the chest, is recorded in a modern work.‡

Dr. Baillie once met with a very unusual stricture in the œsophagus, arising from the puckered state of the mucous membrane, which, as well as the muscular fibres, was quite free from all morbid alteration.

When the diameter of the lower portion of the œsophagus is much diminished, the food often accumulates above the most contracted portion of the passage, which becomes dilated above the obstruction, and is sometimes converted into a kind of pouch, nearly as capacious as the stomach itself. Cases of this description are recorded by Blasius, Haller, and Mayo. In most examples, the dilatation is a general one, comprising the whole circumference of the tube. The formation of a *cul-de-sac* pouch at some particular point is more rare. However, in Dr. W. Hunter's museum may be seen a pouch of this kind, formed at the lower end of the pharynx, and extending down behind the œsophagus. Its origin was ascribed to a cherry-stone, which remained three days in the lower part of the pharynx, where it made a depression, in which the victuals afterward lodged. In about five years the pouch was large enough to hold several ounces of fluid. Its situation and size, particularly when distended with food, occasioned extreme difficulty of swallowing, by which the patient was ultimately destroyed. An example of a pouch at the lower and back part of the pharynx, and extending between the spine and œsophagus, so as to cause great difficulty of swallowing, is recorded by Sir C. Bell.—(*Surg. Obs.*, p. 64.) After death the bag was not found to be covered by muscular fibres, as in Mr. Ludlow's case, but consisted of a

protrusion of the inner coat between the strong muscular fibres of the pharynx. The patient used to suffer as much from flatulence as from dysphagia, and in consequence of the entrance of bougies into the opening of the sac, it was difficult to pass them. Pouches of this description are sometimes the result of abscesses, which burst into the pharynx. An instance in which there were two large sacs reaching from the pharynx along the sides of the œsophagus and trachea, and betwixt the former and the vertebræ of the neck, was seen by Sir C. Bell. The mechanical operation of these pouches, and their valvular communications with the pharynx, by which the food that insinuated itself into them was confined there, occasioned the patient's death from irritation and inanition.*

Cases of dysphagia attended with the formation of the above kind of sacs, have been pronounced inevitably mortal.—(*Jourdan, in Dict. des Sciences Méd.*, tom. x., p. 439.) This melancholy prognosis, it is to be presumed, would be fully warranted where the sac was the consequence of a scirrhus disease of the œsophagus; yet if Dr. Odier has taken a correct view of a case that occurred at Geneva, an example, in which the œsophagus was in a scirrhus state, and there was a large prominent pouch on each side of the neck, yielded to medical treatment.‡ The food which the patient, a young nobleman, took, commonly remained in these sacs an hour or two, and was then thrown up. Hemlock pills were prescribed, and a bandage applied to the protuberance. As soon as the pills were rejected, which, like the food, they were sure to be in an hour or two, their place was supplied by others, so as to let the hemlock constantly act on the seat of the disease. The patient soon experienced relief, and was gradually cured; the pouches disappeared; the aliments descended into the stomach; and the œsophagus recovered its former calibre.—(*Edin. Med. Convers.*, vol. iii., p. 193.)

[In stricture from chronic thickening of the mucous membrane, the patient feels, instead of actual pain, a sort of pressure or tightness, either in the course of the intestinal canal, or about the shoulders. He points out the exact part of the œsophagus in which the obstruction is situated; and the lower this point is, the

‡ *Revue Méd.*, Février, 1823. Some cases of softening and attenuation of the parietes of the œsophagus, followed by its rupture, are quoted by Andral.—See *Anat. Pathol.*, t. ii., p. 246. In every instance of this kind hitherto reported, the tube gave way in the thoracic portion of the œsophagus near the cardia. The change is analogous to what has been considered by Hunter as the digestion of parts of the stomach by the gastric juice after death, and, indeed, it may depend upon the action of the same fluid, under particular circumstances.—Ed.

* *Surg. Obs.*, p. 71. With the assistance of Mr. Broxholm, of Sunbury, the editor removed from the late Mr. Champaign of Halliford, a tumour that was situated just below the occiput. Its consistence was that of cartilage, and its size that of a large orange. It had been growing many years. The reason which induced the patient at length to submit to an operation, was, a serious difficulty of deglutition, which he supposed might depend upon the irritation of the tumour. After the removal of the swelling, the wound healed up very well, but no amendment took place in the power of swallowing, and the patient, who could hardly take any nourishment for two or three weeks, died in a very emaciated state, about two months after the removal of the tumour. On dissection, a thickening of the parietes of the œsophagus was detected, attended with a very close stricture, and a pouch above it, containing some orange pips.

greater reason has the practitioner to suspect a thickened state of the coats of the canal. The unpleasant sensations sometimes extend to the cardiac orifice of the stomach; but they are only felt when the patient makes attempts to swallow. In the early stage, the food does not return into the mouth till long after a meal, sometimes not till four or five hours afterward. As the disease makes progress, however, the return is quicker, and the quantity of aliment brought up again larger. Lastly, when the case approaches its fatal termination, the food is often rejected almost as soon as the effort is made to swallow it.

Dysphagia arising from scirrhus of the œsophagus, is attended with symptoms very similar to those of stricture. Pain, and inability to swallow solids, are the early symptoms. After a time the passage of fluids is arrested; they remain for a short time in the canal, and, distending it, create a sense of suffocation. At length, they are partly rejected by an inverted action of the œsophagus through the nose and mouth, and the rest passes down with a gurgling noise.—(*Monro's Morb. Anat. of the Gullet, &c.*, p. 326.) By careful and experienced observers, however, some circumstances have been noticed by which a scirrhus of the œsophagus is more particularly characterized. The patient is conscious of a dull pain and oppressive tightness, not only when he attempts to swallow, but at other times; and, if credit can be given to Wichmann, who first made this remark, the disagreeable sensation and the difficulty of swallowing cease in a great measure when the patient lies down upon his back. In addition to these particulars, Richerand's observation merits attention, namely, that a bougie is generally more easy of introduction, than in cases of stricture. The disease is reported to be sometimes met with in very young subjects as well as others, Percival having observed it in a child only thirteen years of age, and Wichmann in three children under eight. A question, however, here presents itself, namely, whether these were examples of true scirrhus disease of the œsophagus, or only scrofulous swellings of the lymphatic glands, which are well known to be particularly common in young subjects?]

Where osthecia, or an ossific diathesis, is present, the stricture sometimes assumes a bony hardness; and Metzger (*Advers. Med.*, vol. i., p. 175) gives a pitiable case of this kind, in which the passage was so narrow, that the unhappy patient perished altogether of hunger! At times, indeed, the œsophagus has become entirely imperforate, either from the increasing contraction, or from the enlargement of internal or surrounding tubercles: of the former, Rhodius relates a singular case.—(*Cent. ii. Obs. 46*.) Examples of the latter have occasionally followed smallpox,* or strumous indurations.†

In a few instances, half the length of the

œsophagus has been completely gorged by a single fleshy or glandiform excrescence. One patient thus afflicted died of marasmus in the seventh month from the commencement of the disease, and in the prime of his life. The tumour reached from the middle of the canal to the cardia, and so thoroughly blocked it up that a probe was with difficulty passed into the stomach on examining the part after death.—(*Edinb. Med. Essays*, vol. ii., art. xxiv.) An analogous case is recorded by Sir C. Bell.—(*Surgical Obs.*, p. 79.)

Of stricture of the œsophagus, it is often difficult to trace the remote causes. A neglected catarrh; common sore throat; smallpox; syphilis; a highly nervous or spasmodic diathesis; the smoke of tobacco; the use of the *datura stramonium* (*Eph. Nat. Cur.*, Dec. iii., Ann. i., obs. 79; and Ann. ii., obs. 68); the abuse of mercurial preparations; drinking too largely of coffee, or any other fluid immoderately hot or cold; and an inflammation of the pharynx and œsophagus produced by swallowing soaps, &c. or other injuries, are various remote causes mentioned by writers. A temporary contraction of the œsophagus is said to have also been produced by worms in the stomach and intestines; and in one or two instances, apparently, by worms lodged in the hepatic and common duct.—(*Eschenbach, Vermischte Bemerkungen*, i.) [With respect to some glandular swellings and tubercles, by which the œsophagus becomes obstructed, there can be no doubt that they depend upon scrofula.† Of the causes of scirrhus of the pharynx and œsophagus, nothing certain is known. Under the head of *dysphagia constricta*, the learned author of this work has included many diseases of very different characters, as common stricture, from a thickening of the mucous membrane of the œsophagus; scirrhus and various sarcomatous indurations and thickenings of the parietes of the canal; and obstruction of it by glandular swellings and other tumours, either situated between its coats or growing from them.

No medicine has the power to remove a permanent stricture of the œsophagus arising from a thickened and contracted state of the mucous membrane. This is a very different case from spasmodic constriction of the canal, where no organic disease prevails, and the power of antispasmodic medicines, emetics, cold drinks, cold lotions, blisters, and alteratives, is considerable.

* Sir C. Bell, in *Surgical Obs.*, p. 83; Dr. Cumin, in *Edin. Med. Chir. Trans.*, vol. iii., part ii.; and a case under Dr. Renton, as quoted in Abercrombie's *Pathol. and Pract. Researches on Diseases of the Stomach, &c.*, 2d ed., p. 98.

† This is generally the case, but tubercles may obstruct the œsophagus in persons free from any suspicion of scrofulous taint. Preternatural irritability of the stomach may be the sequel of gastric irritation, as in yellow fever or in stricture of the pylorus, and the long continuance of either of these states may lead to disease of the œsophagus, and to the formation of tubercles. A case of this kind, occurring in the practice of Prof. Francis, is mentioned in the *Trans. of the New York Lit. and Phil. Society*, vol. i., p. 506.—D.

* Act. Hafn., vol. i., obs. 109. *Eph. Nat. Cur.*, Dec. ii., Ann. ix., obs. 45.

† Mauchart, *Diss. de Strumâ Œsophagi, hujusque Coalitu, &c.* Tubing., 1742.

In the instance of permanent stricture, the proper course is the use of the bougie; and where the attempt to dilate the part brings on violent spasm and great disturbance of the constitution, even caustic bougies may be tried, as recommended by Sir Everard Hoine. In general, however, the common bougie should be preferred, and the armed one employed only in formidable and unyielding cases. In proportion as the stricture gives way, the size of the bougie must be increased. If an example were to present itself, in which the dysphagia was known to depend upon the connexion of one or more preternatural pouches with the pharynx or œsophagus, combined or not with a stricture or other disease of the passage, the means from which the greatest relief might be expected would be, I think, the introduction of an elastic gum tube, by which the food might be prevented from distending the pouch, and the stricture at the same time dilated. Whether also the obliteration of the pouch might be safely attempted by throwing an astringent injection into it, as suggested by Sir C. Bell (*Surgical Obs.*, p. 69), future experience must determine. Elastic gum catheters are of important use in diseases of the œsophagus, not only as a means of effecting the dilatation of strictures, but as a contrivance for feeding the patient, without any action or disturbance of the diseased part itself. A proof of the accuracy of these remarks will be found in the particulars of Dr. Cunin's interesting case already referred to.

In the early stage of a scirrhus or sarcomatous obstruction of the œsophagus, leeches, blisters, or issues on the throat, may be tried, together with an emetic, a course of the compound calomel pill, and occasional aperient medicines. The issues on the sides of the throat, and the use of bougies, Sir C. Bell assures us, will effect a cure when there is a mere thickening from common inflammation or scrofulous action. Were a case of this description to present itself to the editor, he would be disposed to give the internal and external use of iodine a fair trial. Except in the above examples, however, little benefit can be expected from this or any other plan. In these cases, as well as in those of common stricture, the patient should generally be fed by means of an elastic gum tube, passed from the nostril down the œsophagus.] In an early period of the disease, some benefit has been derived from hemlock and ammoniated copper. And sometimes mercury carried to the point of salivation,* has been found serviceable. Dr. Munkley relates one case of great severity, and even of some years' standing, in which mercury carried to the effect of pyalism, was perfectly successful.

A stomach syringe, for diluting and washing away various poisons introduced into the stomach, whether by design or accident, was [first suggested by Renault in his work on poisons. Dr. Monro afterward gave drawings of instruments for the removal of laudanum from the

stomach.—(*Thesis de Dysphagia*, Edin. 1797.) However, until Dr. Physic (*Eclat. Repert.*, vol. iii., p. 111; also *Gibson's Surgery*, vol. ii., p. 362) proved the utility of the stomach-pump in the case of a child poisoned with laudanum, the invention gained little attention. As now perfected by Mr. Read and others,] it appears to be admirably adapted to the joint object of enlarging the diameter of the œsophagus by a gradual pressure, and of conveying any quantity of liquid food that may be desirable. The instrument, as brought into notice by Mr. Jukes, consists of an elastic gum tube, a quarter of an inch in diameter, and two feet and a half in length, terminating in the lower extremity, or that introduced into the stomach, in a minute globe of ivory with various perforations, which for the present purpose must be omitted, and fitted at the upper end, either by a screw or a plug, to an elastic bottle of sufficient size to contain at least a quart of liquid, with a stopcock fitted to it, as in the hydrocele bottle. Instead of the bottle, a pewter syringe may be adapted, of equal capacity, and used in the same manner.

The bottle or syringe being filled with warm water, and fitted to the tube already introduced into the stomach by the mouth or a nostril, on turning the stopcock the water or other liquid may easily be forced into the stomach, and withdrawn by a reverse action: and hence laudanum, or any other poison capable of dilution, may be pumped up in a diluted state till the stomach is entirely unloaded; and liquid food may be introduced to any extent, at option. Mr. Jukes has tried the instrument on himself, as well as on various patients, with complete success, in one or two cases after ten drachms of laudanum had been swallowed for the purpose.—(*Lond. Med. and Phys. Journ.*, No. 43, p. 334.)

SPECIES II.

DYSPHAGIA ATONICA.

ATONIC DYSPHAGIA.

DIFFICULTY OF SWALLOWING FROM DEBILITY OF THE MUSCLES OF DEGLUTITION.

THE external tunic of the œsophagus is muscular, and the muscular fibres are both transverse and longitudinal. The propulsion of the food from the fauces into the stomach, commences in the action of the circular fibres of the pharynx, which contract in succession, and in a downward direction; and as this direction is continued to the muscular fibres of the œsophagus, the swallowed morsel is carried forward into the stomach by a progressive or peristaltic action.

Now, in all cases of debility in the muscles of deglutition, the contractile action of their fibres, and consequently their propulsive power, is lost or enfeebled, and a difficulty of swallowing must be the necessary consequence. [Persons of advanced years are most subject to dysphagia from paralysis of the œsophagus; though the disease sometimes occurs in the middle period of life, and even in youth. Thus, Dr. Monro (*Morbid Anat. of the Human Gullet*, &c., p.

* Rush, *Inquiries and Observations*. Brisbane, Select Cases. Dobson, *Med. Obs. and Inq.*, vi.

231, 232), records one instance of it, brought on in a country lad, nineteen years of age, by a previous febrile attack; and another case where it came on suddenly in a soldier, aged thirty-two, whose mouth was also drawn a little to the left side, indicating the connexion of the complaint with apoplexy. In atonic or paralytic dysphagia, patients generally swallow solids more easily than fluids, the conveyance of which into the stomach requires a greater effort and a more complete agreement among all the organs concerned. A probang may readily be introduced down the passage, without producing any aggravation of the complaint, as it does in cases of spasm. The patient cannot fix upon any particular point as the situation of obstruction, and he is not sensible of any pain, tightness, or feeling of weight, except at the periods of making an attempt at deglutition. When the paralysis is complete nothing can be swallowed, and it is indispensable to feed the patient by means of a tube. When liquids pass down a certain way, and are then forced up, the paralysis probably occupies only a part of the œsophagus. Atonic or paralytic dysphagia may be the effect of apoplexy and other diseases, or injury of the brain; also of fevers; of exposure to cold and damp; and of disorder of the digestive organs. It is a symptom of the last stages of fever, and phthisis pulmonalis. In such cases a small quantity of any fluid frequently cannot be swallowed, because it does not give a sufficient stimulus; but deglutition will be executed if a large spoonful be given.—(*Monro, op. cit.*, p. 234.) The treatment of atonic dysphagia must vary according to the nature of the cause. When the disease is the consequence of apoplexy, the means best calculated to lessen the difficulty of swallowing, are the same as those required for the relief of the original complaint. When the dysphagia has been associated with pain at the pit of the stomach, difficulty of breathing, palpitation, and flatulence, a cure has been accomplished by cordial volatile medicines, blisters, issues, and five grains of the pill *myrrhæ comp.*, given every night at bedtime.—(*Monro's Morbid Anat.*, &c., p. 231.)

In many cases, repeated blisters to the throat and chest, which stimulate from without, and tonic and astringent gargles, as of alum, catechu, rhatany, port-wine, and decoction of cinchona, which stimulate from within, will afford relief. Stimulating sialagogues may also be employed with advantage.

A draught of cold water drunk frequently during the daytime, and especially at night and morning, has also, as a tonic, been frequently useful. And if the habit be relaxed or irritable, the same tonic plan should be rendered general as well as local; and be especially combined with exercise, sea-air, sea-bathing, [electricity, galvanism, and the use of spirituous fomentations, as strong camphorated liniments, to the throat and neck. When no organic disease of the brain or spinal marrow is present, electricity is deemed one of the best remedies: several examples of its efficacy are given by Dr. Monro,

and in one interesting case, the patient could only swallow when seated on the electrical stool. In some cases recorded by Tode and Wichmann, a cure was effected by the free exhibition of quassia.]—(*Dict. des Sciences Méd.*, tom. x., p. 444.) Hard study must be relinquished, and, if possible, anxiety of mind

SPECIES III. DYSPHAGIA GLOBOSA. NERVOUS QUINSY.

DIFFICULTY OF SWALLOWING FROM WIND IN THE STOMACH, SPASMODICALLY COMPRESSED INTO THE FEELING OF A BALL ASCENDING INTO THE ŒSOPHAGUS, AND PRODUCING A SENSE OF STRANGULATION.

FROM this feeling of a hard ball in the throat, the species is in the present system distinguished by the specific name of *globosa*. It is peculiarly common to persons of a nervous or spasmodic temperament: and is hence called by Dr. Darwin and many other writers, *globus hystericus*, and by Dr. Heberden, *nervous quinsy*.

Most frequently it occurs as a mere symptom of the hysteric or hypochondriacal affection; and on this account is regarded as such alone by many nosologists. It is, however, often to be traced in sudden gusts of passion, as fear, grief, and anger, especially in young subjects, whose passions have never been disciplined; and at times exhibits so much violence as to threaten suffocation. In nervous habits, I have frequently met with it as a pure idiopathic affection; and, in a few instances, in persons who are not thus constitutionally predisposed to it.

Two clergymen of this metropolis, who bear an equally high character for pulpit eloquence, and have a very sufficient self-possession, have been occasionally under my care for some years, in consequence of this complaint. One of them has most commonly been attacked during dinner; the regular action of the muscles, in swallowing, being converted, from debility of the organ, into the irregular action of spasm. The other received the first paroxysm while reading the service in his own parish-church, and was incapable of proceeding with it. In this case, the regular action of the muscles of the glottis, in speaking, excited irregular action in those of the œsophagus, from contiguous sympathy. And the effect was so considerable, that, when the clergyman came to the same passage of the liturgy on the ensuing Sunday, he was obliged to stop again, for he found he could not get through it. But he preached with as much fluency as ever; and this, too, with nothing more than a syllabus of his discourse before him. It was many weeks before he could summon courage to make another attempt in the desk; and his first effort was even then made in another church, and before another congregation. In this he was fortunate enough to succeed; and he has now entirely overcome the morbid habit.

In both these cases, I have found the most effectual remedy at the moment to be a tumbler of cold water swallowed gradually, and the application of a handkerchief, dipped in cold

water, to the throat. The spasm thus counteracted soon ceases; and, in the cases before us, has returned not only less frequently, but with far less violence. Yet during the intervals, general tonics, a light diet at regular hours, and as much as possible horse exercise, have been had recourse to, and contributed their respective services.

The usual antispasmodics, ammonia, ether, camphire, assafoetida, and even laudanum, had formerly been tried, but, I was told, with little success.

When ether is had recourse to, whether in this or any other affection, the best means of dissolving it is a preparation little known in our own country, but which is introduced into the French Pharmacopœia under the name of *Oleum de vitellis ovi*, obtained by evaporating the mixed yolks of eggs to about half; the oil is produced from this by pressure, but it must be afterward filtered through paper to become refined.

SPECIES IV. DYSPHAGIA UVULOSA. UVULAR DYSPHAGIA.

SWALLOWING OBSTRUCTED, OR TROUBLESOME,
FROM RELAXATION AND ENLARGEMENT, OR
FROM DESTITUTION, OF THE UVULA.

THE uvula is sometimes enlarged from inflammation; but, in such case, the disease, for reasons already stated, belongs to another class. In the inflammatory state, the uvula is hot, acutely painful, of a red or livid colour, and deviates, as it enlarges, from its proper form. In the species before us, its natural form and colour are scarcely interfered with, excepting that, as it grows larger and longer, it also grows paler. It is soft, relaxed, and œdematous.* [The affection is a chronic elongation and thickening of the part; an occasional consequence of syphilis, protracted fevers, and the use of mercury. It also sometimes proceeds, in professional singers, from immoderate exertion of the vocal organs. The patient has a sensation, as if the throat were blocked up by some largish body; the annoyance is considerable; and he is compelled to be continually coughing and swallowing his spittle. Some cases depend upon relaxation of the azygos, or levator muscle of the uvula.]

The complaint, therefore, in this variety, requires to be treated with spirituous and astringent stimulants. Gargles of alum, Cayenne pepper, or port-wine, are the local applications commonly used, and they should be combined

with cathartics and general tonics. [The remedy on which Dr. Granville chiefly relies, is a gargle containing lunar caustic; the strength of which should be varied, according to the state of the uvula itself, and the nervous irritation in the system. Another useful application, mentioned by the same physician, is a powder composed of equal parts of muriate of ammonia and nitrate of potash, with a quarter of Cayenne pepper. This produces great immediate irritation, followed by copious salivation, and expectoration of thick mucus. The powder should be rubbed on, with a camel-hair brush, twice or thrice a day. Gargles, made with a proportion of sulphuret of potash, are in common use among professional singers, for improving the defect of their voices, connected with relaxation of the uvula; and Dr. Granville thinks the practice justified by analogy; sulphuret of potash being known to have, in croup, the power of converting the stridulous voice into a deep full tone, and being in fact the remedy for which Bonaparte awarded a prize of 1000 Napoleons, during the epidemic croup which raged in Paris, in 1812.* If the disease do not yield to this plan, the elongated and pendulous part must be extirpated.

In a few rare instances, the uvula, and even the tonsils, become hard and cartilaginous; and, in such cases, the morbid portion must be cut away.

The uvula in its natural state appears also to be concerned in deglutition; and, [as one of its purposes is to examine, as it were, the nature of the aliment previously to its being swallowed, and by its sympathetic relations to excite an aversion in the gastric organs to substances not of a fit consistence and quality to be conveyed into the stomach, it is endowed with a much higher degree of sensibility than the rest of the soft palate. By means of this quick sensibility, and the sympathy of the rest of the organs of deglutition with it, they are in all probability excited duly to perform the harmonious and successive actions by which the function of deglutition is accomplished.] And hence, when, from ulceration or any other cause, the uvula is lost or deficient, deglutition is rendered more or less troublesome, and even difficult. In this case, the healing art can administer nothing, and habit becomes the only physician. Examples are related, however, of so total a loss of the uvula, from gangrene, or the barbarous cruelty of cutting out the tongue, that the sad sufferer has been compelled to force the food

* In syphilitic ulceration of the soft palate, the uvula is often considerably enlarged, and so distended with serum, that it exhibits quite a transparent appearance. One gentleman, whom the editor lately attended, was in the habit of making a forcible expiration to throw the uvula in this state forward, for the purpose of its being inspected. Andral states, that œdema of the uvula may be idiopathic, connected with certain kinds of angina, or accompanying induration of the tonsils.—(Anat. Pathol., t. ii, p. 236).—Ed.

* Lancet, No. 377, pp. 280, 281. According to Dr. Granville, who was for several years physician to the opera company, the uvula, in deep base singers, is thick and corneous, but thin and very pointed in the light, silvery, soprano singers. The observations of M. Bennati leave no doubt that the uvula and soft palate have considerable influence over the modulation of the voice; and he has demonstrated that these organs contract in proportional degrees to the ascent of the several musical notes.—(See *Annali Universali* for June, 1830; *Bulletin des Sciences Méd.*, for May, 1830; and *Lancet*, No. 377).—Ed.

in every meal into the œsophagus with his forefinger.*

SPECIES V.

DYSPHAGIA LINGUOSA.

LINGUAL DYSPHAGIA.

SWALLOWING OBSTRUCTED, OR TROUBLESOME, FROM PROTRUSION OR MAGNITUDE OF THE TONGUE.

THIS species exhibits itself under the two following forms or varieties:—

- | | |
|-----------------|---|
| a Exsertoria. | Tongue extended from the |
| Lolling tongue. | mouth, often with enlargement of its substance. |
| β Ranula. | Intumescence of the salivary glands or ducts. |
| Frog-tongue. | |

It is necessary, as in the last species, to distinguish both these affections from inflammatory enlargements. [According to the editor's views of this subject, the only cases which strictly accord to the author's classification, are certain chronic,† and frequently congenital, enlargements of the tongue; for the examples produced by mercury and poisons, though included in this section, are in reality inflammations, and ought therefore to be arranged with other cases of inflammation. Galen mentions an instance of a prodigiously large tongue, which was neither in a scirrhus, œdematous, nor inflamed state.—(Lib. i., cap. 9, de diff. morb.) Scaliger also refers to a man, whose tongue was of so extraordinary a size, *ut mendacii suspicio silentium indicat*.—(Exercit. 199, cap. 1.) Marcellus Donatus was acquainted with a merchant at

* The simple loss of the uvula would scarcely create so complete an inability to swallow as what is here described. Many persons who have lost the whole of the uvula from syphilitic ulceration, continue to swallow without inconvenience. Cutting out the tongue in the rude way referred to in the text, would certainly render deglutition more or less difficult; but would not generally be accompanied by the excision of the uvula; nor, if such excision took place, would the dysphagia depend much upon it, but upon the loss of the tongue.—Ed.

† In scirrhus disease within the mouth, while the cellular tissue is becoming more and more thickened and indurated, the other tissues around it often have a tendency to waste away; they become less and less visible, and at length disappear, their place being supplied by a hard, homogeneous, white or grayish mass.—(Andral, Anat. Pathol., tom. ii., p. 237.) This fact has been particularly noticed by Sir Charles Bell, and also by Dr. Hodgkin, in his valuable paper upon adventitious structures.—(See Med. Chir. Trans., vol. xv., p. 225.) In one case of scirrhus of the tongue, this organ, which was enlarged and singularly hard, presented nothing but a whitish substance, resembling the indurated cellular substance surrounding old ulcers of the skin, and in the midst of which some traces of slender, pale, muscular fasciculi were noticed, nearly obliterated by the pressure of the thickened cellular tissue. This was very exuberant on the dorsum and edges of the tongue, where it formed knobs, on several of which the mucous membrane was in an ulcerated state.—Ed.

Mantua who was in the same condition.—(Hist. Mirab., lib. vi., cap. 3.) T. Bartholine quotes a case communicated to him by J. Valeus, in which a girl's tongue was as thick as her arm, and required to have a portion of it removed. The same author likewise describes a child, whose tongue, which was from the first larger than those of other children, became at length equal in size to a calf's heart.—(Cent. 2, Hist. Anat., 22.) Similar instances of spontaneous preternatural growths of the tongue are recorded by Bardet (*Bulletin de la Soc. d'Erreux*, No. 23, p. 67) and Maurant.—(*Journ. de Med.*, an 1762, tom. xv.) Another example of congenital enlargement of the tongue is described by Percy. The malformation had increased so much by the time the patient reached her eighteenth year, that it was impossible to see the sides and under surface of the tongue; and though she could speak and sing, she was obliged to push her victuals to the back of her mouth with her fingers, in order to be able to swallow them.—(*Dict. des Sciences Méd.*, tom. xxvii., p. 246.) A very interesting case is that of Philibert Hænnum, who was born with a very large tongue, pendulous from the mouth. No material increase of the part was afterward perceived till the boy was eight years of age. At this period it was of a purple colour, and covered with a thick, foul coat of mucus. It descended three inches below the chin; its apex was rounded; the teeth of the lower jaw were displaced by it; its base was two inches and a half thick; and the whole cavity of the mouth was filled by it; so that respiration could only be carried on through the nostrils, and nothing but liquids could be swallowed. The patient was relieved by the amputation of about a pound of the tongue, and the extraction of the misplaced teeth.—(MM. Percy and Laurent, vol. cit., p. 246.)

In another very similar case, nearly an English pound of the tongue was extirpated with ligatures by Dr. Mireau. In this instance, not only did the four lower incisor teeth project with their edges forward in the horizontal position, but the alveolar process was also displaced.

It is justly remarked by MM. Percy and Laurent, that cases of the above description must all be referred to the principle by which other *lusus naturæ* and extraordinary congenital enlargements of parts are produced; and that they are widely different from the instances more commonly recorded, which are specimens of glossitis, and generally occasioned by acrid, venomous substances, inflammation, or, what used to be termed metastases. In many of the congenital cases, however, it appears, that a further increase of the tongue proceeded from the irritation of the part by the teeth of the lower jaw, and the consequently augmented determination of blood to it.

Besides the impediment to deglutition, the enlarged and protruded state of the tongue gives rise to a constant loss of saliva, with which the victuals are therefore not duly impregnated; digestion is impaired, and the health suffers.

The operation of removing the redundant

portion of the tongue is the only means of relieving the above description of cases. Whether it should be done or not, must depend upon the degree of inconvenience caused by the swelling and size of the part. In cases of glossitis, on the contrary, this practice is quite improper; for, when they will not yield to the removal of their particular cause, and the employment of antiphlogistic treatment, one or more free and deep incisions in the dorsum of the tongue will generally afford prompt relief. The merit of making the efficacy of this method properly known to the surgical profession belongs to M. Delamalle, who wrote some interesting observations on the subject in the *Mem. de l'Acad. de Chir.*; but the practice was first introduced by Camerarius, Zacutus Lusitanus, and other older surgeons. In the modern periodical journals, we are constantly meeting with proofs of its success.—(See *Edinb. Med. and Surg. Journ.*, No. 92, p. 76.) Sometimes, however, the necessity for deep incisions has been superseded by bleeding from the raninal veins, blistering the throat, and other antiphlogistic measures.—(See *Edinb. Med. and Surg. Journ.*, No. 93, p. 451.) In one very singular instance, where the enormous swelling was confined to the left half of the tongue, and bounded by the middle line, the application of six leeches two or three times to the inflamed part produced a speedy subsidence of the swelling.—(Graves, in *Dublin Hospital Reports*, vol. iv., p. 43.) In all cases of obstructed deglutition by enlargement of the tongue, the use of elastic gum tubes for the conveyance of food and medicines into the stomach under urgent circumstances, should never be neglected.

M. Magendie, in the *Bulletin of the Philomathetic Society of Paris*, for September, 1817, quotes the case of a Jew, who was able to double his tongue backwards, and plunge it with the greatest ease into the pharynx; and tells us of a boy who acquired the same power by imitating the Jew. The first efforts of the latter were unsuccessful; but at length he ruptured the frænulum, and a hemorrhage ensued, which, nevertheless, did not alarm him; for he found from that moment that he could pursue the imitation more perfectly; till, by continued repetition, he too acquired the singular faculty of swallowing, in the same manner, his own tongue, without the least inconvenience to his respiration.

But the substance of the tongue, under this variety, is not always enlarged. M. Fournier knew a handsome young woman, sixteen years of age, who, although she had a long neck, had a slender and still longer tongue, inasmuch that she could protrude and extend it to her bosom without stooping her head. And he tells us of another female whom he saw at Berlin, with a tongue astonishingly wide, but as thin as a cat's. When this woman laughed, the tongue covered the whole of her mouth, and hung out like folds of drapery. It was always cold, and communicated a most frigorific sensation to the hand of another person.—(*Dict. des Sciences Médicales*, art. CAS RARES.)

[The Ranula, or frog-tongue, is a tumour under the tongue, consisting sometimes of a dilata-

tion of the excretory duct of the sublingual gland; sometimes of a dilatation of the excretory duct of the submaxillary gland. The first case is denoted by its globular shape, and its situation exactly under the tongue; the second by its oblong figure, and its lying towards the side of that organ. The disease is most frequent in children; but is also met with in adults. The contents of the swelling are generally a viscid, transparent fluid, like white of egg. The disease arises from an accidental obstruction or obliteration of one of the above-mentioned ducts. When neglected, the tumour sometimes becomes so large that it occupies the greater part of the mouth; forces the tongue backwards; impedes suction, mastication, and deglutition; obliges the patient to breathe entirely through the nostrils; propels outwards the canine and cutting teeth; and even forms a prominent swelling below the chin.—(See *Petit, Traité des Mal. Chir.*, tom. i., p. 184.)

When the tumour is recent, and not very large, it may be cured by making a free opening in it, and maintaining the aperture for some time by means of a small tube or tent. When, however, the swelling is of a considerable size, and of long standing, and the cyst is thick and indurated, a portion of the latter part must be removed.]

The irritation and enlargement proceed occasionally from a morbid secretion of calculeous matter. Hence, when a ranula has been opened, the surgeon should always examine with a probe whether any calculeous matter is lodged in it; and, if it be so, it should be at once extracted. M. Fournier records one case, in which a stone formed under the tongue, and at length acquired the size of a pigeon's egg, accompanied with great pain and profuse salivation: a cure was effected by removing the morbid concretion.

SPECIES VI.

DYSPHAGIA PHARYNGEA.

PHARYNGEAL DYSPHAGIA.

SWALLOWING OBSTRUCTED BY A POLYPOUS EXCRESCENCE IN THE PHARYNX.

THE variety, produced by a polypous excrescence in the pharynx, is added. Sir Astley Cooper tells us that he has seen two cases of it; one in a Spanish gentleman who had previously consulted various surgeons at Paris, but apparently without success. It was of the colour of the mucous membrane of this portion of the alimentary tube, beginning from the fold over the palato-pharyngeus, and hanging down like a sausage into the pharynx. By great efforts the patient could regurgitate it into his mouth. A ligature was passed round its root without much difficulty, and it separated in eight days. The second case was similar in appearance, but not quite so large, and grew still more from the root of the tongue. It was removed in the same manner, and with equal success.*

* Lectures on Surgery, vol. ii., p. 356, 8vo., 1825. This addition was found among Dr. Good's papers, subsequently to the completion of the third edition.—Ed.

[The particulars of another instance of a difficulty of swallowing, from the growth of a polypus from the lining of the pharynx, were communicated, two or three years ago, by Kergardec, to the Royal Academy of Medicine at Paris.—(*Dict. de Méd. et de Chir. Pratique*, art. *Dysphagie*.) The true cause of the dysphagia, which had been treated as a nervous affection, was only made out after death, when the parts were dissected.]

GENUS IV.

DIPSOSIS.

MORBID THIRST.

THE DESIRE FOR DRINKING EXCESSIVE OR IMPAIRED.

BETWEEN the present and the ensuing genus, entitled LIMOSIS, or MORBID APPETITE, there is a close natural connexion, though their position is in different and even distinct organs.

The sense of hunger is well known to be seated in the stomach; and that of thirst in the mouth and fauces. [Thirst is a feeling of a still more urgent kind, and requiring instant satisfaction still more imperiously, than hunger; particularly in warm climates, or when any of the watery secretions are augmented, as in dropsy and diabetes. It is one of the most distressing symptoms in fevers and inflammatory complaints, especially in inflammation of the stomach. Hot spices, saline substances, and, in particular, common salt, increase it, as do all causes augmenting the different secretions. The end of drinking seems, therefore, to be for the repair of the losses of our fluids. If thirst be not satisfied, a general irritation comes on; the sensation of dryness in the mouth and fauces increases, and is accompanied with a burning feel, and a quickened pulse. But, although thirst appears at first very oppressive, drink is by no means so necessary to the continuance of the life of every animal, as food. Several species of warm-blooded animals, as mice, quails, parrots, &c., can subsist without drinking; and individuals of the human race have been known, by perseverance, to conquer the sensation of thirst. Sir G. Baker has recorded a memorable example, in the Transactions of the College of Physicians, of a man, who lived in perfect health for many years, without drinking.]

Thirst and hunger may be compared to two sisters, united together for the common purpose of rendering the animal attentive to the preservation of its own existence. When their call is obeyed, they are a source of pleasure; when it is neglected, or resisted, they are a cause of great and even fatal suffering. But, in the production of these two very different results, pleasure and pain, thirst is far more energetic and intense than hunger. The quickness with which the taking of drink appeases the first of these sensations, contrasted with the slowness with which solid aliment is necessarily conveyed into the stomach, perhaps, may tend in some measure to explain the really greater enjoyment generally felt in quenching thirst than in satisfying hunger.

In the great object for which thirst and hunger are instituted, namely, the nourishment of the body, the importance of the latter sensation is sometimes represented as greater and more evident than that of the second. Solid aliment, it is said, yields the essential constituent parts of the blood; and the utility of drinks, in relation to this fluid, is not always so manifest. Yet, how can this view be adopted, unless we shut our eyes to the large proportion of aqueous fluid in the blood, and to the immense quantity of water continually thrown out of the circulation by the lungs, kidneys, skin, and the secreting organs in general? The cessation of pleasure, however, the crisis to which the satisfying of either of these sensations leads, it is true, is less strongly marked with respect to thirst than hunger; and the disgust, experienced from cramming the stomach with solid food, can scarcely be said to be producible by taking a redundant quantity of beverage. Indeed, with regard to thirst, drunkards appear incapable of reaching that point which, in the use of solid aliments, may be regarded as satiety. This difference probably depends upon the stomach immediately ridding itself of drink, while chymification requires the food to be retained in it a considerable time. Hunger and thirst differ strikingly from one another in the time and situation of their development, as well as in their local and general phenomena. Thirst, contrasted with hunger, comes on suddenly, and, if it be not quenched, it creates a state of suffering,—real pain; it is not at all like what, in relation to hunger, is called an appetite, which enters into the class of agreeable sensations. In thirst, the mouth, and especially the throat, are affected; in hunger, the stomach is the seat of uneasiness. Thirst, even when not very ardent, is accompanied with a true local and general excitement; while hunger, if at all protracted, occasions chilliness, paleness, and a disposition to fainting. The differences between hunger and thirst, when long continued, and assuming the character of diseases, or rather, between the effects of a total abstinence from drink and those of a complete abstinence from solid food, are still more strongly marked. To use a term employed by Brown, the state of *sthenia*, of *erethismus*, of dryness, and of local and general heat; the increased activity in the general and capillary circulations; the energy of the external senses, of the whole nervous system, and of the muscular organs; the results of thirst, form a very manifest contrast to the prostration of every power of the constitution, to the languor of all the functions, and to the true *adynamia*, produced by unappeased hunger. Death, which is the end of both these scenes, takes place much sooner from thirst, and the more so, because no remission occurs in the cruel and progressive course of its symptoms. Death from want of solid food always comes on more tardily, and its phenomena, which are characterized by irregular paroxysms, are attended with remissions of greater or less duration.

But nothing is a better illustration of the dif-

ferences between hunger and thirst, than the influence of disease over them. Who does not know, that one of the first effects of most diseases is to augment thirst, and to make the patient need a larger quantity of drink, while the appetite is more or less completely annihilated, and a necessity for abstinence produced? Throughout the course of diseases, while thirst continues, the appetite cannot return; and even if it were to do so, in this state of things, it would only be a fallacious indication of a fictitious want, that could not be safely satisfied. The decline of indisposition, and the approach of convalescency, denoted by the subsidence of thirst, have also, as one of their surest harbingers, the return of appetite. And with regard to therapeutic means, is it not equally a fact, that beverages which assuage thirst create appetite? that certain medicines, particularly antispasmodics and opium, which diminish hunger, excite a good deal of thirst? and, lastly, that all generous alcoholic wines which appease or delude the sensation of hunger, produce at the same time quite an opposite effect upon thirst?

Though the seat of thirst is now generally assigned to the mouth and fauces, some physiologists so far dissent from this doctrine as to refer the seat of thirst partly, also, and even principally, to the stomach. They argue, that, as this organ is the instrument of hunger, it must, by analogy, be likewise that of thirst; and that heating drinks and food, which merely glide over the throat, produce thirst chiefly by their action on the stomach, as is proved by the circumstance of thirst not being felt till digestion is going on in the stomach, and long after their application to the pharynx. They further argue, that the thirst following a meal, is actually quenched by beverages which merely touch the parts in the mouth and throat momentarily, but remain more or less time in the stomach. They likewise take into consideration, that various aliments of mild qualities, like farinaceous substances, which do not at all irritate the pharynx in deglutition, excite a considerable degree of thirst after their introduction into the stomach. The only means of relieving thirst so brought on, is to swallow plenty of fluid; for every other attempt at deceiving the patient's feeling is to little purpose.

It is conceived that other observations tend to raise additional uncertainty respecting the true seat of thirst. Dropsical diseases, diabetes, profuse suppuration, copious hemorrhages, &c., are cases in which the animal economy is deprived of a large quantity of fluid, without the physical state of the pharynx or stomach appearing to be more particularly affected, than any other part of the body. Nay, it is asserted, that some rare examples have been met with, in which an irritation, a dryness, and redness of these organs, were not accompanied with the least degree of thirst; and it is remarked that, whatever may be the cause and intensity of this sensation, it may certainly be appeased by the warm bath, clysters, and the injection of liquid into the veins; plans which replenish the sys-

tem with fluids, but have no specific action either on the throat or stomach.

Although these reflections seem to the editor to bear more upon the question concerning the causes of thirst, than that relating to its seat, they are highly interesting, confirming the fact, that the present subject is involved in a great deal of mystery, and pointing out the obscurity that attends our internal sensations, compared with such as are derived from without.

Many vague hypotheses have been suggested, as explanations of the immediate cause of thirst. The least plausible ones must here be passed over in silence. By some physiologists, thirst is imputed to the dryness of the nervous papillæ of the pharynx, arising from a diminution of the salivary and mucous secretions. Yet, in numerous cases, thirst exists quite independently of a want of moisture in the pharynx; while such beverages as are calculated to prevent the dry state of that organ do not always succeed in quenching thirst; and, in many instances, the best means of assuaging it, whatever may be its violence, are certain general therapeutic plans, which cannot possibly operate by moistening the pharynx, or its nerves.] In thirst, there is, perhaps, always a sense of dryness in the fauces; and yet dryness of this organ does not appear to be the cause of thirst; at least, the intensity of the feeling does not appear to depend on the intensity of the dryness: for there is sometimes but little thirst, where the tongue, to its very roots, is covered with a thick and dry crust, as in the acme of continued fevers: while it is often vehement under the influence of violent passions, and intolerable on a surcharged stomach, when the tongue and fauces have no dryness whatever.

[Another class of physiologists, considering, on the one hand, the purpose of thirst, which leads us to take only such fluids as are fitted to dilute the blood and the secretions; and observing, on the other, the powerful influence that copious evacuations, by perspiration, diarrhœa, diabetes, and serous extravasations, have over this sensation, attribute the immediate cause of thirst to the abstraction of the aqueous part of the blood. Bichat, who was inclined to adopt this theory, conjectured that the introduction of water into the veins would, by mixing with the venous blood, have the effect of quenching thirst in the same manner as drink taken in the ordinary way. This conjecture is now ascertained to be a fact. By injecting water, milk, whey, and other fluids into the veins, Baron Dupuytren has frequently appeased the thirst of animals subjected to experiment, and long exposed to a burning sun. By varying such experiments with liquids known to be agreeable or disagreeable to dogs, he found, that the animals derived from these liquids, so employed, the same sensation of taste as if they had been given by the mouth. In fact, when milk was thrown into the jugular vein, the dogs made a lapping motion, just as if they were really taking the milk up with their tongues.

Some analogous experiments were made by Professor Orfila. In his valuable researches on

Toxicology, he had frequent occasion to tie the œsophagus in dogs, in order to hinder the expulsion of poisons which they had swallowed. For the purpose of appeasing their thirst, excited by the fever resulting from the extensive wound in their necks, he injected water into their jugular veins. This method of quenching thirst, the only one practicable while the œsophagus was tied, was performed in a great number of instances, and always gave immediate relief. The blood of animals which had been long in a thirsting state, was also submitted to distillation, and the diminution of its aqueous part was always found to be in proportion to the length of their abstinence from drink.—(*Dict. des Sciences Méd.*, tom. li., p. 469.) The principal fact interfering with the foregoing theory, is that of the frequently sudden production of thirst, without any previous abstinence from drink, sufficient to justify the suspicion of the watery part of the blood having been in any way particularly lessened. But although much obscurity prevails concerning the efficient cause of hunger and thirst, their final cause is sufficiently obvious; they are the means by which we are warned of the necessity of supplying the system with materials requisite for its existence. They belong to that class of actions which are termed appetites; where an effect, which is a compound of a physical and a mental operation, is connected with an evidently useful purpose in the animal economy.]—(*Bostock's Physiology*, vol. ii., p. 531.)

The common modes of quenching these agonizing sensations, are well known to be eating and drinking; yet, when these cannot be indulged in, other modes may answer as a substitute. Thus, violent pressure against the coats of the stomach, whether externally or internally, is well known to take off the gnawing sensation of hunger; and stimulating the fauces, to take off the burning faintness of thirst. It is on this last account that chewing a mouthful of hay, alone, or merely moistened with water, proves so refreshing to a tired horse, and is found so serviceable when we dare not allow him, in the midst of a long stage, to slake his thirst in the natural way. Savages and savage beasts are equally sensible of the benefit of pressure in the case of hunger, and resort to it upon all occasions where they have no opportunity of taking off the pain in the usual way. The manis, or pangolin, that swallows its food whole, will swallow stones, coals, or any other substance, if it cannot obtain nutriment; not that its instinct deceives it, but for the purpose of acquiring such a pressure as may blunt the sense of hunger, which it finds intolerable. Almost all carnivorous beasts pursue the same method; and a mixed mass of pieces of coal, stone, slate, and earth, or other hard materials, is often met with in the stomach of ostriches, cassowaries, and even toads. The Kamtschadale obtains the same end by swallowing sawdust; and some of the northern Asiatic tribes, by a board placed on the region of the stomach, and rudely laced behind with cords, drawn tighter and tighter, according to the urgency of

the uneasiness. In our own country, we often have recourse to a similar expedient, and only exchange the tightened stomach-board for a tightened handkerchief.*

It is possible, therefore, temporarily to overcome these natural sensations without the natural means; and the passions of the mind have as strong an influence on both as any of the substitutes just adverted to. Thus both are completely lost beneath the sudden communication of news that overwhelm us with grief or disappointment. So Van Hehnont tells us that, happening to dislocate his ankle while walking with a good appetite to dine with a friend, his appetite immediately forsook him, but returned as soon as the joint was replaced, though the pain continued for some time with little alteration. There are some passions, however, as those of rage and eager desire, which, while they repel the sense of hunger, increase that of thirst. But they prove equally the close connexion of both feelings with the state of the nervous system generally, and the strong and extensive influence which is sympathetically exercised over them.

MORBID THIRST, as a genus, is new to the science of Nosology, and hence the two species which belong to it have hitherto, in almost every instance, been separated from each other, and thrown loosely into remote parts of the classification. Dr. Young, however, offers an exception to this remark; for, with his accustomed accuracy, he has united them under a common head. The genus being new, it has hence been necessary to create a new name for it; and that of dipsosis, from *διψαω*, "to thirst," has appeared not only most pertinent, but most consonant with the nomenclature in common use, which has naturalized various terms derived from the same root; as *adipsia*, *polydipsia*, *phobodipsia*, this last being a synonyme for hydrophobia.

The two species of the genus are the following:—

1. Dipsosis Avens. Immoderate Thirst.
2. ———— Experts. Thirstlessness.

SPECIES I.

DIPSOSIS AVENS.

IMMODERATE THIRST.

CONSTANT DESIRE OF DRINKING, WITH A SENSE OF DRYNESS IN THE MOUTH AND THROAT.

SIMPLE thirst is a natural, immoderate, or indistinguishable thirst,—a morbid feeling. Yet even the latter is less frequently an idiopathic

* Capt. Kennedy, who was shipwrecked in 1769, relieved his thirst by soaking his clothes twice a day in salt water, and putting them on without wringing. He says (*Dodsley's Ann. Reg.*, 1769), "After these operations the violent drought went off, and the parched tongue was cured in a few moments after bathing and washing our clothes; and at the same time, we found ourselves as much refreshed as if we had taken nourishment. Four persons in the boat who drank salt water, became delirious, and died; but those who avoided this, and followed the above practice, experienced no such symptoms."—D.

disease than an individual symptom of some other complaint, or some peculiar state of body, the removal of which will alone effect its cure. [Whether, in the strictest sense of the expression, immoderate thirst is ever an original idiopathic disease, appears to the editor very doubtful; and in the cases where it has been assumed to be so, probably this inference was drawn merely from the circumstance of no other disorder in the system being apparent. How often, however, is the practitioner compelled to observe only symptoms, and remain ignorant of their primary cause!]

I have at this time under my care a young lady of about thirteen years of age, in other respects in good health, who is tormented with a thirst so perpetual, that no kind or quantity of beverage seems to quench it for more than a few minutes. Emetics and other purgatives have been tried in vain. Squills and other nauseating expectorants seem to promise more success. It has now lasted for several weeks.

The most grateful palliatives are the vegetable acids, and especially acescent fruits, and a decoction of sorrel-leaves (*rumex acetosa*, Lin.) slightly inspissated with gumarabic or some other mucilage, and sweetened to meet the palate. Liquorice, which, among the Greeks, had so high a reputation for quenching thirst as to be honoured with the name of ἀδύρον, "the thirst extinguisher," has little or no effect. And it is probably true, as suggested by Dr. Cullen, that it only acts in this manner when the root is well chewed, by which means the salivary excretories become stimulated to an increased secretion of fluid.

In a foreign medical miscellany we have reported to us a case of the same kind, brought on by drinking a cold beverage during the paroxysm of a fever, that continued for more than a twelvemonth.—(*Hœuermann, Bemerkungen*, i., p. 28.) And in another foreign journal, we have an account of this disease as epidemic among children.—(*Gazette de Santé*, 1777, p. 93.)

The quantity actually drunk is sometimes enormous. Four hundred pints of wine and water have, in some cases, been swallowed daily.

As a symptom, excessive thirst is chiefly found in the hot fit of fevers, in dropsy, dysentery, diabetes, diarrhœa, and other discharges. It is also frequently excited in wet-nurses, as soon as the child takes hold of the nipple; but perhaps is felt most intolerably under the torture inflicted to compel a confession of guilt; in which case it is said to form the worst part of the suffering. The agony of violent thirst, brought on by bodily suffering, is well depicted in the description of the fatal scene in the memorable Black Hole of Calcutta.—(*Annual Register*, 1758.)

* A case, however, occurred within the observation of Drs. Hosack and Francis, of a gentleman then aged about 35 years, who had no recollection of having ever experienced the sensation of thirst. He had long enjoyed good health, and was very muscular; even when using excessive quantities of stimulating condiments, as cayenne pepper, &c.,

SPECIES II.

DIPSOSIS EXPERS.

THIRSTLESSNESS.

CONSTANT WANT OF THIRST.

CONSIDERING that thirst is a natural feeling, and contemplating the vehemence of this feeling when extreme, it is not a little extraordinary that instances of its total absence should ever occur. Yet there are many animals, and warm-blooded animals too, that never require drink, and consequently never thirst; as mice, quails, parrots. Here, however, the want of thirst, or desire to drink, is a natural condition in the economy of these animals. In man, and animals constituted like man, with a constitutional proneness to thirst, and an instinctive urgency to quench it by drinking, this want of desire can never take place without disease.* [Whether this, however, should be referred to disease, or a natural idiosyncrasy, may be questionable. While immoderate thirst, unattended with any other manifest disorder of the constitution, has been set down by nosologists as an original idiopathic disease, thirstlessness, we perceive, is not viewed in this light, but regarded here as an effect of disease. In opposition to this conclusion, it should be recollected that some individuals have lived, seemingly in good health, without drinking. M. Bouffard records one instance in which a young lady, twenty-two years of age, passed whole months without drink, yet appeared to be well in every other respect.—(*Dict. des Sciences Méd.*, tom. li., p. 465.) Facts of the same kind are reported by Sir G. Baker.]—(*Med. Trans.*, vol. ii., p. 265, &c.) Cases of thirstlessness are not by any means frequent. Sauvages mentions two instances that occurred to himself. In the one, the patient, a learned and excellent member of the Academy of Toulouse, never thirsted, and passed months at a time without drinking, even in the hottest part of the summer: in the other, the patient, who was a female of a warm and irascible temperament, abstained from drinking for forty days, not having the smallest degree of thirst through the whole of this period.—(*Nosol. Method.*, vol. i., p. 770, 4to edit.) Neergaard, as quoted by Blumenbach, has furnished us with other examples;† and M. Fournier informs us that one of his most intimate friends reached, not long since, the age of forty-eight, without ever having drunk of any fluid, or been thirsty; but he was accustomed to eat voraciously. It is singular that he should have died of *dropsy* of the chest, apparently the result of a second bleeding for some accidental malady.—(*Dict. des Sciences Médicales*, art. CAS RARES.)

he had no desire for fluids. In those who confine themselves to vegetable food exclusively, the disposition for drinks is much diminished. The case of Mr. Waterton, the distinguished traveller, is an instance of this kind.—D.

GENUS V.

LIMOSIS.

MORBID APPETITE.

THE APPETITE FOR FOOD IMPAIRED, EXCESSIVE,
OR DEPRAVED.

THE sensation of hunger, as observed already, is seated in the stomach, and, like that of thirst, is a natural or instinctive desire.* It may, however, become diseased, and lose its natural character; and this in various ways, and accompanied with various sets of symptoms, each of which lays a foundation for a distinct species. Like the species of the last genus, however, they have hitherto been omitted in most nosologies, or loosely scattered over different parts of the classification, though they evidently belong to a common family, and should be contemplated in a concentrated view. It is for this purpose they are now united under the banners of a single genus, to which I have ventured to give the name of *LIMOSIS*, from *limos*, "hunger," being the root of various terms current in the medical vocabulary; as, bulimia, alimia, alimon, alimonia, alimentum; though the last three have been commonly misderived by the lexicographers from *alo*, "to nourish;" unless *alo* itself be from the same source.

The species that properly appertain to it are the following:—

1. <i>Limosis Avens.</i>	Voracity.
2. ——— <i>Expers.</i>	Long Fasting.
3. ——— <i>Pica.</i>	Depraved Appetite.
4. ——— <i>Cardialgia.</i>	Heart-burn, Water- Brash.
5. ——— <i>Flatus.</i>	Flatulency.
6. ——— <i>Emesis.</i>	Sickness, Vomiting.
7. ——— <i>Dyspepsia.</i>	Indigestion.

SPECIES I.

LIMOSIS AVENS.

VORACITY.

INSATIABLE CRAVING FOR FOOD.

THIS affection may be produced by a sense of faintness and inanition, without any known cause of exhaustion; probably in consequence of some organic error in the stomach by gluttony, or an habitual indulgence in large and frequent meals; or by exhaustion from hard exercise, long fasting, fevers, or excessive discharges: thus offering the three following varieties of this species:—

<i>a</i> <i>Organica.</i>	From a feeling of faintness and inanition.
Canine appetite.	
<i>β</i> <i>Helluonum.</i>	From an habitual indulgence in large and frequent meals.
Gluttony.	
<i>γ</i> <i>Exhaustorum.</i>	From exhaustion, as the consequence of hard exercise, fevers, or excessive discharges.
Hunger of exhaustion.	

* Dr. Beaumont (Exp. and Obser. on the Gastric Juice, &c.) considers the sensation of hunger

There are many persons who from birth, or a particular period of life, without any habit of indulgence, are capable of taking into the stomach an enormous quantity of food, and cannot be satisfied without it, from a constant sense of faintness and inanition; and who by no means increase in bulk in proportion to the quantity swallowed; being often, on the contrary, slender and emaciated.

It is difficult to account for this effect in every case; but there is great reason to believe, that, in general, it depends upon some error in the structure or position of the stomach, by which means the food passes out of this organ as soon as it is introduced into it. [A very curious example of an approach of the stomach to the perpendicular direction, attended with a singular structure of that organ, has been lately recorded by Mr. Hart; but, unfortunately, the particulars of the appetite and digestion in this subject could not be ascertained.*] Ruysch gives a case, in which the dianter of the pylorus was considerably enlarged from relaxation; and there are others, in which it has been changed from its natural to a lower or dependent position, in consequence of the left side of the stomach being elevated by a dropsy of the ovary, or an enlargement of the liver. The existence of a double stomach, or of an immediate insertion of the ductus communis choledochus into the stomach, though noticed as causes by Blasius and Bonet, is more doubtful.† In the hunger of general exhaustion, forming our third variety, we know it to be produced by the secretion of an extraordinary quantity of gastric juice, by which the food is digested almost as soon as it reaches the digestive organ. That mimic feeling which is commonly known by the name

to be produced by a distention of the gastric vessels, or of the vascular or glandular apparatus, which secretes the gastric juice.—D.

* See Dublin Hosp. Reports, vol. iv., p. 326, &c.

† In a galley-slave, noted for voracity, Vesalius ascertained that the bile was poured directly into the stomach. The stomach of the celebrated glutton, Tarrare, of whom some particulars will presently be detailed by Dr. Good from the history published by M. Percy (see Mém. sur la Polyphagie, Journ. de Méd., &c., par MM. Corvisart, Leroux, &c., t. ix., p. 87), was remarkable for its great capacity. In the instance recorded by Cabrol, in which the bowels were only three feet long, the size of the stomach was prodigious. On this subject, Professor Andral puts a judicious question; viz., whether the extraordinary dimensions of the stomach, sometimes noticed in the bodies of persons known to have been gluttonous eaters, may not be the simple effect of the immoderate quantities of food habitually introduced into that organ, and not the primary cause of the voracious appetite itself? In this case, it might be expected that the stomach would increase in bulk, like all other parts whose functions are in a state of considerable activity.—(See Andral's Anat. Pathol., t. ii., p. 192.) However, in one remarkable instance of extraordinary congenital bulimia, reported in a modern work, the stomach, instead of being increased in size, was found after death particularly small, though the individual lived to the age of thirty-two.—(See Broussais, Annales de la Méd., Oct., 1832.)—Ed.

of *false appetite*, was supposed by Galen to be produced by some acrimony in the stomach. Upon the theory of Dr. Wilson Philip (*Treatise on Indigestion*, &c., p. 73, 1824), its real cause should be an excessive secretion of gastric juice itself; for it is the flow of this material over the interior of the tunic of the stomach, that, according to him, excites the sense of hunger. It should, however, be recollected, that, if this sensation be not indulged within a few hours, and in weak stomachs within a much shorter period of time after its commencement, it suddenly dies away, and is succeeded by anorexy; although it is reasonable to suppose, that there is then in the empty stomach a much larger quantity of the secretion.

[Some cases of voracious appetite seem explicable on another principle, connected with the theory frequently entertained of the proximate cause of hunger, namely, that it is a sensation excited in the stomach by sympathy with the wants of the constitution at large. Thus, it is often noticed in young persons, who are growing with great rapidity, and in pregnant females; examples, as Andral truly observes (*Anat. Pathol.*, t. ii., p. 192), strongly illustrating the necessity of frequently searching for the cause of a functional disorder far from the organ which is the seat of it. If any circumstance impede the nutrition of the body, hunger still remains, although the stomach be distended. Thus, in a case recorded by Morton, where the thoracic duct was ruptured, the child died in a horrible state of marasmus, notwithstanding it was continually taking enormous quantities of food to appease the violent cravings of its hunger. The excessive voracity of persons afflicted with a scirrhus pylorus (see *Monro's Morbid Anat. of Human Gullet*, &c., p. 334), or with disease of the mesenteric glands, is well known. In a very interesting case recorded by M. Gondret, where the whole of the stomach was thickened by scirrhus, and its capacity so reduced that it was scarcely capable of holding eight or ten ounces of fluid, the patient suffered much from a continual and painful sensation of hunger.—(*Magendie, Journal de Physiol. Expér.*, tom. i., p. 281.) The same fact is also exemplified in individuals whose intestinal canal is preternaturally short, as in the remarkable example described by Cabrol, where the length of intestine, between the pylorus of an enormous stomach and the anus, did not exceed three feet. And even in convalescents, sadly emaciated by severe diseases, and whose appetite is sometimes almost insatiable, it seems as if a full state of the stomach could hardly lull the general feeling of inanition. The present affection sometimes comes on merely as one of the symptoms of certain degrees of chronic gastritis. In this case, no sooner is a small quantity of food introduced into the stomach, than a complete loss of appetite succeeds the irresistible craving previously experienced, and various dyspeptic complaints follow. Many patients affected with chronic gastritis, feel an oppressive dragging sensation in the epigastrium, which is mistaken for hunger.]

Whatever be the cause, the quantity of food devoured by persons labouring under this affection is enormous, and in some instances almost incredible. Dr. Mortimer (*Phil. Trans.*, vol. xliii., p. 366) relates the case of a boy only twelve years old, who, from a feeling of inanition, had so strong a craving that he would gnaw his own flesh when not supplied with food: when awake, he was constantly eating: the food given him consisted of bread, meat, beer, milk, water, butter, cheese, sugar, treacle, puddings, pies, fruits, broths, potatoes; and of these he swallowed, in six successive days, three hundred and eighty-four pounds eight ounces avoirdupois; being sixty-four pounds a day on the average. The disease continued for a year: and in this case we have a clear proof, that the feeling of hunger did not depend upon extraordinary secretion of gastric juice producing a rapid digestion; for the food was usually rejected soon after it had been swallowed, but whether without passing, or after having passed into the duodenum, it is impossible to say. And there are other cases, related by Lommius, of a similar kind.

In various instances, however, the food thus voraciously swallowed does appear to be digested, and that almost as soon as taken. Of this the case of the notorious Tarrare, as related to the National Institute by M. Percy, is a striking illustration. Before his enlistment, he was in the habit of devouring enormous quantities of the coarsest flesh, fruits, and roots; and, subsequently, he was found, after swallowing his own rations, to feed on the refuse of his comrades' messes, or offensive meat thrown on the dunghills; and to devour cats, dogs, and serpents. M. Fournier tells us, that, at seventeen years of age, when he weighed only one hundred pounds, he could devour in the space of twenty-four hours a quarter of beef as heavy as his body; and that, on one occasion, when in the army, he devoured in a few minutes a dinner prepared for fifteen German labourers, and composed of various substantial dishes. There is a singular story, that the French commander attempted to turn this wonderful voracity and extent of stomach to a good account, by employing it as a safe deposite for a letter of secrecy, which he wished to send to a French officer, at that time in the hands of the enemy. He sent for the man, showed him a wooden case containing the letter, and having put him into good-humour by treating him with thirty pounds of liver and lights, prevailed upon him to swallow it, and to depart with all speed to the enemy's quarters. Tarrare, however, was taken prisoner in the attempt; and while in prison, passed the box by stool before he could meet with the officer, but immediately swallowed it again, to prevent its falling into the enemy's hands. He was strongly suspected of cannibalism; and was often repulsed with difficulty from the ward appropriated to the dead. He at length fled from the army in consequence of a rumour that he had devoured a child sixteen months old, which had suddenly disappeared. The alvine evacuations of this man were not immoderate; but after

gorging his stomach he slept and emitted torrents of perspiration, a symptom common to the disease. He fell at length into a hectic, and died of marasmus.—(*Dict. des Sciences Médicales*, art. CAS RARES.)

Voracity is often a symptom of some other affection; it will sometimes occur in the most capricious manner during pregnancy, often in the middle of the night, or at some other unexpected period; when the patient, with a sudden sense of faintness and inanition, will perhaps devour an inordinate quantity of almost any food that can be obtained at the moment; though in many cases there is a fanciful longing for a particular kind, as for herrings, of which Tulpus (lib. ii.) gives an instance of a lady, who in this state devoured four hundred at a meal. In these instances, it is probable that the urgent desire becomes a stimulus to the secretions of the stomach, and that a greater quantity of gastric juice is in consequence poured forth.

In like manner, voracity and the sense of hunger occur also as a symptom in many cases of helminthia, or worms in the stomach or duodenum. But from the emaciation which usually accompanies such persons, it is most probable that the inanition or emptiness of the stomach is here produced, not by a rapid or elaborate digestion, but by an irritable state of the muscles of the stomach, which contract too readily, and force the food into the intestines before chymification has taken place. In the *Phil. Trans.*, Dr. Burroughs relates the case of a patient, who, from this cause alone, was rendered capable of devouring an ordinary leg of mutton at a meal for several days together, and fed greedily at the same time on sowthistles and other coarse vegetables.

The best means of treating idiopathic voracity must be as variable as the efficient that produce it. When we have reason to ascribe it to a morbid state of the stomach in respect to tone or secretion, purgatives, and especially those that are warm and bitter, as aloes, may be successful. Stimulating stomachics have been found equally so; whence Galen very judiciously recommends frequent and small doses of brandy, and Riverius, of ambergris. If these do not succeed, the stomach should be kept for some days in a state of constant nausea: and, with this view, as well as with that of destroying the morbid irritation on which the voracity depends, opium will often be found a highly salutary medicine. If the disease be produced by worms, or any other remote irritation, it can only be conquered by conquering the primary affection. And if it depend on a preternatural enlargement of the pylorus, a perfect cure is beyond the reach of art; though some benefit may be derived from strong external pressure.*

* In a case under M. Rostan, in 1819, ice, administered inwardly, considerably abated for a time the fury of the patient's hunger.—(*Med. Gazette* for July, 1833.) Several pieces of tænia were afterward expelled by means of purgatives. As her hunger decreased, her appetite became

The second variety, resulting from a gluttonous habit, is far more common, and very readily produced; insomuch, that there is not perhaps a corporate town in the kingdom that does not offer abundant examples of it. It is, in fact, one of the numerous evils to which idleness is perpetually giving birth; for, let a man have nothing to do, and he will be almost sure, whenever he has an opportunity, to fill up his time by filling up his stomach: and hence the lazy train of servants that vegetate from day to day, almost without locomotion, in the vestibule, hall, and other avenues of a great man's house, eat three or four times as many meals as their masters, who may possibly be employed, from morning till evening, in the courts of law, the committee-rooms of parliament, or in a fatiguing maze of commercial transactions.

In tracing the cause of this voluntary disease, we have no difficulty whatever. When the stomach becomes accustomed to distention, it is never easy without it; and at length requires to be constantly full to be free from disquiet. It is also well known, that every sense grows more acute the more it is employed: and hence the taste and longing of the glutton become more alive to what is relishing and savoury; he enjoys such indulgences more than other men, and turns with disgust from foods that are plain and simple. On this account, the difference between the craving of a pampered appetite and that of real hunger is extreme: the former, whatever be its longing, can only satiate itself on delicious and high-seasoned dishes; the latter is content with a fare of any kind, and enjoys the plainest more than the richest.

By constant distention the capacity of the stomach may become enlarged, and not only hold, but require for satiety, a far more copious quantity of food than in its natural state; and hence one cause of that enormous bulk of the organ which has often been mistaken for dropsy. Bonet gives a case, in which, owing to a mistake of this kind, the patient was actually tapped, and the contents of the stomach hereby discharged, death following soon afterward. Magendie relates an instance that occurred to himself, in which the patient, then seventy-two years of age, vomited in a few minutes, from a stomach enormously distended, as much as filled two large pails.

It is not often that we are asked to attempt a cure of this complaint: it generally proceeds till the tone of the stomach is exhausted by its hard labour, and the cure is effected by the introduction of dropsy, or some other disorder worse than itself, which utterly extinguishes all appetite whatever. The man, nevertheless, who would honestly undertake to reclaim himself from this mischievous habit, and to acquire a better, should proceed in his career gradually; for organs that have long been under the influence of perpetual excitement, would lapse into atony upon the sudden adoption of a severe

depraved, so that she would devour the raw lights of slaughtered animals, and browse upon grass.—Ed.

counter-plan. The food should gradually be plainer, less in quantity, and repeated at a greater distance of time; while the intervals should be filled up with some pleasant and active pursuit, that may wholly engross the attention; for the surest way for such a man to produce faintness, flatulency, and uneasiness in his stomach, is to think about it. The bowels will at first, perhaps, be costive; but this may easily be remedied by occasional doses of the warmer and bitter purgatives, as aloes, colocynth, and rhubarb; which will operate as usefully by their tonic as by their aperient qualities.

The voracity produced by an exhausted state of the system, is rarely of difficult removal; for, in general, it requires good plain food, and abundance of it. It is most usually consequent upon rapid growth of the body in the period of youth, fevers, excessive discharges, especially from the bowels or bloodvessels, diabetes, long fasting, severe and uninterrupted exercise; and particularly the union of the last two, as often occurs in shipwreck, or the retreat from an enemy. It happens not unfrequently that, in such cases, the stomach occasionally overloads itself, and throws back some part of what has been swallowed. But this is of little importance, and often proves serviceable, by more effectually inculcating moderation, than can be accomplished by medical precepts.

SPECIES II. LIMOSIS EXPERS. LONG FASTING.

LOSS OR WANT OF APPETITE, WITHOUT ANY OTHER APPARENT AFFECTION OF THE STOMACH.

The causes that lay a foundation for this species are numerous, and some of them are accompanied with a slight diversity of symptoms. The following are the chief varieties it offers to us:—

- | | |
|---------------------------------------|--|
| a Defessorum. | From too great fatigue |
| Want of appetite from exhaustion. | or protracted fasting. |
| β Pathematica. | From violent passion |
| Want of appetite from mental emotion. | or other absorption of the mind. |
| γ Protracta. | From habit, or other cause, enabling the system to sustain almost total abstinence for a long and indefinite time without faintness. |
| Chronic fasting. | |

Muscular exertion and long fasting, in a vigorous constitution, prove often, as I have just observed, the most powerful incentives to hunger. But, even in the most robust frame, if these are carried beyond a certain limit, the appetite palls, and is recovered with great difficulty; while, in the feeble and delicate, a very little exercise, and a slight protraction of a meal beyond the accustomed hour, and especially where the attention is directed to it, and hangs upon the delay, is productive of the same effect. In all

these cases, the stomach is best re-excited to its proper feeling by half a wine-glass of sherry or madeira, with a crust of bread or piece of biscuit; or, if there be very great languor, by a few drops of laudanum in a teaspoonful or two of aromatic spirit of ammonia; while the interval should be filled up by what is most likely to attract the attention; for one of the surest re-venters, in uneasiness of the stomach, is a strong excitement of the mind.

I have just said, that a strong excitement of the mind is one of the surest remedies for general uneasiness of the stomach; and every day shows us how powerfully this acts in repressing or taking away the painful sensation of hunger. No man, perhaps, ever had an appetite for food under a full influence of the depressing passions, as fear or grief: he may eat from persuasion, or a sense of duty; but he eats without desire, or any craving sense of hunger. Hence those who are suddenly deprived of their senses by an overwhelming and unexpected evil, pass days and nights without food of any kind, exclaiming, perhaps, in the language of King Lear—

— “ When the mind’s free,
The body’s delicate : the tempest in my mind
Doth from my senses take all feeling else,
Save what beats there.”

Even where the mind is simply but entirely abstracted, and lost in itself while pursuing an abstruse problem or proposition, or adjusting a long train of intricate accounts in a banking-house, the individual has no sensation of hunger; and if left alone, may perhaps persevere, without knowing how the time proceeds, till warned by the darkness of the evening. And hence, La Bruyère, if I mistake not, in one of his pictures of an absent man, describes him, without any deviation from nature, as totally mistaken upon the subject of his dinner. Being summoned by his servant to the dinner-table, he answers that he will come immediately, but still continues in the same place, and indulges in the same reverie, for an hour; when, being summoned a second time, he shows himself angry at the interruption, and still more so at the servant’s stoutly insisting upon it that he had not dined, and that the dishes were still upon the table untouched, while the master contended, on the contrary, that he had actually made his dinner, and that too in the dining-room.

In simple cases of this kind, medicine is not wanted; and in the severer, it is of no use: for it is not in the healing art, under such circumstances, to “minister to a mind diseased.” This must be left to time, the palliatives of friendship, and a change of scene.

The modifications, however, thus far contemplated, may be regarded as mere paroxysms, or acute cases of fasting. The most singular variety of the species consists in what may be called the chronic form of affection, exhibited in those who are able to endure an unbroken abstinence from food, for a long and indefinite period of time, without faintness or inconvenience of any kind.

The medical journals and ephemerides of

different nations, and the transactions of learned societies, abound with examples of this last and most extraordinary modification; many of them extending to a term of time so apparently extravagant as almost to repulse belief, notwithstanding the respectability of the authorities appealed to. It is necessary, therefore, before any such histories are noticed, that I should lay down a few general principles, too well established to allow of controversy, which by their conjoint force may lead us more readily to an admission of such as are founded upon trust-worthy evidence.

1. As the stomach is capable of acquiring a habit of gluttony, or of craving too much, so it may acquire a habit of fasting, or of craving too little: or, in other words, we are as capable of triumphing over the appetite of hunger, as we are over any other appetite whatever.

The desire for food, or the sense of hunger, is very painful for the first two or three days, after which it ceases, and does not return unless stimulated by fresh food. The Chippewas, or native savages of Canada, according to Mr. Long, give striking proofs of the power of the stomach in both extremes—that of hard eating, and that of hard fasting—and, as nearly as may be, at the same time: for, when one of these is on the point of commencing a journey, he devours as much as he would otherwise take in a whole week; the daily allowance of animal food alone being, on such occasions, as Captain Franklin tells us (*Journey to the Shores of the Polar Sea*, p. 250. Lond. 4to. 1823), eight pounds; and, having gorged the stomach, he starts upon his expedition, and commences a long season of severe abstinence.

2. Most of the cases of long fasting that are credibly recorded, have been introduced by a habit of this kind. A few, indeed, have been brought on suddenly; as the result of an accidental shock, inducing an instantaneous and unconquerable antipathy to food: but by far the greater number are of the former kind; and have had their origin in severe abstraction of the mind, by intense study, rigid mortification of the natural feelings in a course of religious discipline, or some growing obstruction, or other affection, in the passage from the mouth to the stomach, or in the stomach itself, producing great uneasiness in deglutition or digestion.

3. When a habit of this kind is once established, and a life of indolence or perfect quiet is associated with it, the quantity of food capable of supporting the animal frame may be reduced to a trifle, and may perhaps consist of water alone for weeks, or even months. We see examples of this in other animals than man. It forms a well-established fact in the history of fishes of various kinds. Even the pike, the most voracious, perhaps, of all fishes, when he has no longer an opportunity of indulging his gluttonous propensity, will both live and thrive upon water alone in a marble basin. The mere air of the atmosphere appears to afford nourishment enough for many forms of animal life. Snails and chameleons have been often known to live upon nothing else for years. Garman

F 2

asserts it to be a sufficient food for the greedy spider; and tells us that, though the spider will ravenously devour flies and other prey, whenever he can seize it, he will not starve upon the spare regimen of air alone. Latreille confirms this assertion by an experiment of his own. He stuck a spider to a piece of cork, and cut him off from all food whatever for four months; at the end of which period he appeared to be as lively as at first. Mr. Baker in like manner confined a beetle under a glass for not less than three years; allowing him nothing but air for his diet: at the expiration of this period he was not only alive, but fortunate enough to effect his escape, and go in pursuit of a more substantial repast. And we are hence prepared to receive with less hesitation than we should otherwise do, the wonderful tales of frogs, toads, lizards, and other reptiles, found imbedded in trunks of trees, or blocks of marble, so deeply seated, that, though exhibiting life and activity on exposure to the atmosphere, they must have been blocked up in their respective cavities for fifty, and in some instances for a hundred years; cut off from every kind of food except the moisture by which perhaps they have been surrounded, and from all direct communication with the atmosphere itself; though, from experiments lately made by Dr. Edwards, it is absolutely necessary that there be an indirect communication of air through the pores or some other opening of the surrounding substance. Fishes, when rendered torpid by being suddenly frozen, are well known to live in this manner through the winter in the Polar Seas, and to be re-quickened into activity by the returning warmth of the summer. "The fish," says Captain Franklin (*Op. Cit.*, p. 248), describing the winter he passed at Fort Chipewyan, on the skirts of the Polar Sea, "froze as they were taken out of their nets, and in a short time became a solid mass of ice; and by a blow or two of the hatchet were easily split open, when the intestines might be removed in one lump. If, in this completely frozen state, they were thawed before the fire, they recovered their animation. This was particularly the case with the carp. We have seen a carp recover so far as to leap about with much vigour, after it had been frozen for thirty-six hours."

4. It may possibly be observed, that these examples are drawn, for the most part, from cold-blooded or exsanguineous animals, and that, in such cases, there is no waste of living matter by the skin, the great vehicle of discharge in animals of a higher rank. But they are drawn from animals that, in their common customs and habits, have the same instinctive craving for food, and the same faculty of converting it into their own substance, by the process of digestion, as animals of any superior class; while a like power of enduring long periods of fasting in a state of inactivity, without any injury to the general health, is quite as conspicuous and incontrovertible in many kinds of warm-blooded animals, and especially those that sleep through the winter season.

[A combination of circumstances is generally

essential to the occurrence, such as a diminution of sensibility and animal heat, a suspension of many of the functions, and especially a stoppage of the secretions and excretions. In this condition, individuals have been known to remain several weeks, and even whole months, without taking any food. Such cases are rare in the human race; but certain animals present us with annual examples of them. At the approach of winter, when they are large and fat, they fall into a torpid state, and continue so until the warmth of the spring returns. During all this time they take no food, their respiration is surprisingly slow; the blood has rather a gentle undulation than a circulation; and the trivial losses which take place are repaired entirely by the gradual absorption of fat. Hence, at the end of the torpid season, the emaciation of animals subject to its influence is very considerable. The emaciation which an accidental or a forced abstinence of long duration brings on man, and the generality of quadrupeds, is also notorious. A hog, weighing about 160 lbs., was buried in its sty for one hundred and sixty days, under a great mass of the chalk of Dover Cliff. When dug out, it weighed only 40 lbs. No food nor water happened to be in the sty when the portion of the cliff fell. The animal had nibbled the wood of the sty, and eaten some loose chalk, which, from the appearance of the excrement, had passed more than once through the body.]—(*Linnean Trans.*, vol. ii.)

5. We have reason, therefore, as well from analogy as from recorded facts, to believe it possible for man himself, under certain circumstances, not indeed to pass life altogether without food, but to lose all relish for it, and to habituate himself to fastings of very considerable length, and only interrupted by slender portions of the sparest and dilutest aliment. [That hunger is a nervous sensation of the stomach seems probable, from its being influenced, like all the phenomena dependant on nervous action, by habit and by mental causes; from its being increased and excited by causes which act on the sensibility of the organ, as by spirituous drinks and spices, even when the stomach is filled; and by its being diminished by means of the contrary kind, as we know that opium will act in deadening the acute feelings of hunger, and that the Turkish and Indian fanatics, called Mollahs and Faquirs, are enabled by this means to support fasts of astonishing duration. The term to which life may be prolonged without aliment, is uncertain. As Dr. Percival has observed, it varies with the incidental circumstances of the case, and the constitutional powers of the individual. It is remarkable, however, that deprivation of food is better borne in some species of disease than in robust health. In certain hysterical cases, and scirrhus affections of the cardia and œsophagus, a degree of abstinence has been endured for many months, which, in other circumstances, could hardly have been sustained for as many weeks. In catalepsy and mania, a very rigid abstinence may be borne for a considerable period.]—(See *Dublin Hospital Reports*, vol. i., p. 159.) The cases are

innumerable in which fasting has been endured ten, twelve, or fifteen days;* and, where there has been access to water, twenty or thirty days.—(*Phil. Trans.*, vol. xiv., p. 577; *Mémoires de Toulouse, l'an 1788.*) Raulin mentions one of fifty-two days, water alone being drunk during the time (*Observations de Médecine*, p. 270); and Dr. Willan attended a patient who had fasted sixty-one days, with the exception of drinking from half a pint to a pint of water daily, mixed with a very small quantity of orange-juice, two oranges lasting him for a week, without any employment of the pulp.—(*Medical Communications*, vol. ii.) But there are other cases related at full length, and upon authority altogether unimpeachable, of fasting continued for twenty-five months (*Bresl. Samml.*, band ii., passim); three (*Phil. Trans.*, 1742, 1777), ten, fifteen, and eighteen years; and, with a very spare and only occasional taste of solid food, through the entire life. In the running commentary to the volume on nosology, I have given several of these histories at some length, and the reader may amuse himself with them at his leisure.†

In most cases, and probably in all, if they had been critically investigated, water, tea, or some other fluid, seems to have been indispensably necessary; and such was found to be the fact in the noted instance of Ann Moore of Tetbury, that has occurred within our own day. That she was an impostor, in pretending to live without any food whatever, is unquestionable; but so very spare was the quantity she had accustomed herself to, from very great difficulty and pain in deglutition, that there is reason for believing that, for many years before she submitted to the test proposed, she had swallowed very little food of any kind, except tea and spring-water. And such is, in truth, the recorded opinion of the active and very intelligent committee, which undertook the trouble of

* Professor McNaughton has recorded (*Trans. of the Albany Inst.*, vol. i.) the case of a man, who lived fifty-three days upon water. In the *New-York Med. and Surg. Journal*, vol. ii., p. 21, Dr. Francis mentions a black woman, afflicted with the disease of obi, who for seven weeks refused food, and took during this time only two cups of wine and water.—D.

† See also *Mém. de l'Acad. des Sciences*, l'an 1764.—Stalpart Vander Wiel, *Observ. Rar.*—*Mém. of the Lit. and Phil. Soc. of Manchester*, vol. ii., p. 467, and two extraordinary cases of fasting, quoted in the *Medical Gazette* for July, 1833. In one of these instances, the patient is stated to have been living six years and a half without swallowing any food, though she moistened her mouth occasionally with water, tea, or whey, which she invariably spat out again. During four years, she had relief only once by stool, and three times by urine. At the age of thirty-five, the catamenia ceased altogether. In the other case, originally published by Professor Ricci, of Turin, the inability to take food continued about three years; and on the death of the patient, who was also a female, the descending colon, and commencement of the rectum, were found so obstructed by the effects of chronic inflammation, that no solid matters could pass along them.—Ed.

watching her night and day for a whole month, in rotation. Absolutely cut off from all fluids as well as solids, this woman was on the point of expiring when she reached the tenth day, and had scarcely strength enough left to confess the fraud she had been induced to practise. Yet the committee thus close their report of her history:—"On the whole, though this woman is a base impostor with respect to her pretence of *total* abstinence from all food whatever, liquid or solid; yet she can, perhaps, endure the privation of solid food longer than any other person. It is thought by those best acquainted with her, that she existed on a mere trifle, and that from hence came the temptation to say that she did not take any thing. If, therefore, any of her friends could have conveyed a bottle of water to her, unseen by the watch, and she could have occasionally drunk out of it, little doubt is entertained that she would have gone through the month's trial with credit. The daughter says that her mother's principal food is tea, and there is reason to believe this to be true."

It is remarked by Hippocrates, that most of those who strictly abstain from food for seven days, die within that period; and that if they do not, and even begin to eat and drink again, still they perish.

Where persons from famine, superstition, severe grief, or any other cause, have persevered in a course of rigid fasting for many days, and the frame is become frightfully emaciated and weakened, the greatest care is necessary in the administration of food; which at first should be light, liquid, and small in quantity; for, not only the stomach, but the organs of assimilation, lose all power by degrees; and if once re-quickened, are very apt to be unduly excited, and induce delirium and fever. It was in this way Dr. Willan lost his patient on the fifteenth day after his return to food, though the regimen adopted was peculiarly promising and judicious.

SPECIES III.

LIMOSIS PICA.

DEPRAVED APPETITE.

APPETITE FOR IMPROPER AND INDIGESTIBLE SUBSTANCES.

In this species there is no want of appetite; often, indeed, an inordinate craving; but, instead of its directing the patient, as in the first species, to palatable and substantial food, whenever such can be obtained, it urges him in preference to the most whimsical and innutritive materials. This character forms the specific definition. The specific name here given is *PICA*. Not that the term has any particular or very obvious merit; for its origin and primary meaning are doubtful; but that, out of many terms with which nosology has been encumbered to express this disease, *pica* appears to be the most general, and there is no sufficient reason for changing it.

Now, an appetite for improper and indigestible substances may be of two descriptions. It may proceed from a want of taste or dis-

crimination, as in infants or idiots; or from a corrupt taste, or corrupt indulgence, often founded on empirical or other dangerous advice, as the eating of chalk or acids to produce a fair skin; and we have hence the two following varieties:

- | | |
|------------------------|--------------------------|
| a <i>Insulsa.</i> | From want of correct |
| Unwitting <i>pica.</i> | taste or discrimination. |
| β <i>Perversa.</i> | From a corrupt taste or |
| Perverse <i>pica.</i> | indulgence. |

The depraved appetite which is sometimes manifest in infants, can only proceed from want of proper management and direction; for nothing is more tractable than the organ of taste in early life. And hence, indeed, it is, that the different nations of the world are brought by habit, and habit almost coeval with their birth, to prefer such kinds of food as their respective climates produce in greatest abundance, or as they obtain by an easy barter of indigenous substances. Thus, the Hindoos live entirely on fruits and grain; the Tonguses, on berries, the refuse lichen found undigested in the stomach of the reindeer, dried fishes, and beasts of prey; the Californians, on snakes, rats, lizards, rabbits, intermixed with the wild herbs of the soil. But, perhaps, there is no stronger proof of the force of habit in forming an acquired taste to be met with in any part of the world, than in our own country; in our exchanging the natural and instinctive desire of a bland and sweet fluid, as milk, for the bitter beverage of tea for breakfast, and beer for dinner.

On this account it is not to be wondered at, that children, without a guidance, or with an improper one, should often acquire depraved or vicious tastes, and be longing for substances that are innutritive, or even hurtful to the general health. Where this propensity has obtained a footing, it may be successfully opposed by discipline, and overpowered by a counter-habit. Among idiots it is incorrigible.

A longing for improper and indigestible substances, however, is often produced by other means, and occurs in persons who are possessed of a sound judgment. It is frequently to be traced as a symptom of some other affection, as pregnancy, hysteria, chlorosis, and perhaps some species of mental emotion: in all which cases, it is only to be cured by curing the primary disorder.* But it sometimes exists as a primary malady, and is then most commonly brought on by a vain desire of improving the beauty of the person, of giving a graceful slenderness to the form, or a languishing fairness to the skin, through the medium of chalk, acids, or other empirical materials. In consequence of which the Greek physicians, in whose day the practice seems to have been more common

* Andral conceives, that *pica* may be one of the phenomena attending chronic irritation of the stomach; but, that in general, the cause of it would be ineffectually looked for in the condition of that viscus alone; the disease being observed to take place principally in certain morbid states, in which the blood and nervous system are primarily affected.—Anat. Pathol., t. ii., p. 194.—Ed.

than even in our own, and this, too, among young men as well as young women, gave to this variety of the disease the name of *puaxia*, *softness*, or *effeminacy*.

Whatever the cause, when this morbid propensity has once obtained a triumph over the natural taste, the substances for which it excites a desire are often not only of the most indigestible, but disgusting quality. We have had examples of an inclination for devouring dirt, cinders, ordure, fire, spiders, lice, toads, serpents, leeches, bits of wood, hair, candles, and more literature, in the form of paper and printed books, than is devoured by the first scholars in Christendom.

Borelli gives us numerous examples of most of these; and some of them of a very extravagant kind:* and those who are desirous of gratifying themselves still further, may have full indulgence by consulting the *Ephemerides of Natural Curiosities*. Mr. John Hunter describes a longing for dirt, in the form of clay or loam, to have been an endemic disease among the blacks in Jamaica.† But he is surpassed by Dr. Darwin, who tells us that he once saw a young lady, about ten years of age, that had filled her stomach with earth out of a flower-pot, and then vomited it up, with small stones, bits of wood, and wings of insects among it.‡

There are other persons who have had a taste for harder substances, and have glutted themselves with stones,§ glass,|| and even leaden bullets.¶ Others, again, have feasted on pieces of money, which have sometimes formed a very expensive repast; for Borelli gives us an instance of a pantophagist who swallowed a hundred louis-d'ors at a meal.** Yet, perhaps, after all, the most marvellous, though certainly one of the most common exhibitions of depraved taste, is an appetite for knives. There is not a country in Europe but has furnished examples of this in both sexes: and hence the medical journals and miscellanies are numerous in their descriptions of London knife-eaters;†† Prussian knife-eaters;‡‡ Bohemian knife-eaters;§§ and even, out of Europe, Brazilian knife-eaters.|||| The wretched patients have sometimes perished shortly after the extraordinary feat; and sometimes dragged on a miserable existence for a few years, before they fell victims to their madness or malady. In a few instances, they have recovered.

In an extraordinary instance of this kind, that not long since occurred in our own country, the knife-fancier, Cummings by name, and by craft a sailor, lived ten years after his first ex-

periment, and occasionally persevered in the same trick during the whole of this time. The rash act is sometimes overcome, and the materials discharged piecemeal; and it might have been so in this man, but for the foolhardiness that made him insensible to the earlier warnings given him, and urged him to a repetition of the offence.* Even the American States seem of late to have furnished us with a similar example, in a young man who had long, we are told, been in the habit of swallowing various indigestible substances, as buttons, musket-bullets, and billiard-balls; and being thus initiated in the art, on June 22, 1822, swallowed not less than fourteen knives within the course of the day. Repentance came too late. He sunk gradually beneath his exploit, and died on the ensuing 25th of August. Two of the knives had been discharged from the body, one was found in the œsophagus, and the rest in the stomach. The same individual is said, on one occasion, to have swallowed a gold watch, with its chain and seal, and to have evacuated them on the ninth day, darkened in colour, but not otherwise injured.†

If this variety should happen to be united, as it sometimes is, with *pica ærens*, or voracity,‡ there may be no bounds to the deglutition, either in quantity or quality.§ M. Fournier, in his *Cases Rares*, has given us an instance of this kind, so extraordinary, that if it had not been most unexceptionably attested, it would not have been credible. A galley-slave, he tells us, of this description, and who was disordered in his intellects, fell at length a sacrifice to a colic, accompanied with a cough; and,

* Marcet, *Trans. of the Medical and Chir. Society*, vol. xii., p. 52.

† New-York Medical Repository, Oct., 1822.

‡ In the *Trans. of the Roy. Asiatic Soc.* for 1833, General Hardwicke has given some details in regard to the East Indian cannibal, or *sheep-eater*, whose disgusting exhibitions have been attested to by numbers. The general, who was an eye-witness, there states, that the sheep-eater had with him two living sheep: after a brief harangue to the multitude around him, he seized the fleece of one sheep with his teeth, and, by swinging his head, flung it on the ground. In this position he tore the animal open, by stripping off the skin from the flank to the breast: he then took out the intestines, thrust his head into the peritoneal cavity, and drank the blood. The rest of the hide was then removed, the ribs separated, the limbs disjointed; each part was rubbed with dust, to dry up the blood, as he said, and to enable him to tear the meat from the bones with greater ease. He then swallowed one mouthful after another with the dust adhering, and the performance was concluded by his collecting some leaves of the mad-dar plant (*asclepias gigantea*) and chewing them; the milky juice of which, he said, would assist digestion. This monster, who was squalid and emaciated, generally ate two sheep at a meal.—D.

§ In the *Medical Gazette* for 1832-33, p. 574, the case of a woman is quoted, who used to devour raw lights, and large quantities of grass. In July, 1823, she ate so copiously of grass and buttermilk for her supper, that she was seized in the night with severe pains in the abdomen; jaundice ensued, and she died in a few days.—Ed.

on opening him, the stomach was found to occupy the left hypochondrium, the lumbar and iliac regions of the same side, and to stretch down into the pelvis. It was of a long, square form, and contained the following substances: a piece of stave *nineteen inches long*, and half an inch in diameter; a piece of a broomstick, six inches long, and half an inch in diameter; another piece of the same, eight inches long; ditto, six inches long; twenty-two other pieces of wood, of three, four, and five inches in length; a wooden spoon, five inches long; the pipe of an iron funnel, three inches long, and one in diameter; another piece of funnel, two inches and a half long; a pewter spoon entire, seven inches long; another, three inches long; another, two inches and a half long; a square piece of iron, weighing nearly two ounces; various other articles, among which were nails, buckles, horns, knives, &c.; the whole weighing about twenty-four ounces avoirdupois.—(*Dict. des Sc. Méd.*, art. CAS RARES.) So that the stomach of this unhappy being became gradually enlarged into a warehouse for all sorts of marine stores, as the term is applied in the present day.

This morbid action is best opposed by giving a counter-action to the organ in which it exists. And hence emetics and purgatives are highly useful. Rhubarb is perhaps the best medicine for the latter purpose; and in moderate doses it should be continued daily; and in combination with it, bark, steel, and other tonics. An acid has often been suspected as the cause of the disease, and the absorbent earths, as chalk, magnesia, and Armenian bole, have been tried in large quantities; but the relief they afford is seldom more than temporary. In the *mal d'estomac*, or *cachexia Africana*, as it has been called, which is the disease of dirt-eating among the negroes referred to by Mr. J. Hunter, perhaps great acidity may exist, and instinctively call for the drier earths, as absorbents.

SPECIES IV.

LIMOSIS CARDIALGIA.

CARDIALGY.

IMPAIRED APPETITE, WITH A GNAWING OR BURNING PAIN IN THE STOMACH OR EPIGASTRIUM, AND A TENDENCY TO FAINT.

THE symptoms laid down in this definition, are sufficiently marked to separate cardialgy from dyspepsy, in which it is merged by Dr. Cullen and various other writers; for, in the last, there is not necessarily a gnawing or burning pain; and the appetite is rather fastidious, than essentially, or at all times impaired. Cardialgy is certainly sometimes found as a symptom in dyspepsy, as it is also in a multitude of other complaints; as flatulency, scirrhus or inflammation of the stomach, worms, retrocedent gout, suppressed menstruation, and various diseases of the heart, liver, pancreas, kidneys, and intestines; in hypochondrias, and in sudden and violent emotions of the mind; but it is likewise found, in many instances, as an idio-

pathic affection, and should therefore be described as such.

Cardialgy admits of the three following varieties:

- | | |
|---|---|
| <p>a Mordens.
Heart-burn.</p> | <p>Gnawing or burning uneasiness, felt chiefly at the cardia, the tendency to faint being slight.</p> |
| <p>β Syncoptica.
Sinking heart-burn.</p> | <p>The pain or uneasiness extending to the pit of the stomach; with anxiety, nausea, coldness of the extremities, failure of strength, and great tendency to faint.</p> |
| <p>γ Sputatoria.
Black-water.
Water-brash.</p> | <p>Burning pain extending over the epigastrium; and accompanied with an eructation of watery fluid, usually insipid, sometimes acrid.</p> |

The first variety is perhaps the most common form of the disease. And as the gnawing or burning pain is in this case felt chiefly at the cardia, or upper orifice of the stomach, the specific name of cardialgy is derived from this symptom. The cardia is indeed generally supposed to be the immediate seat of affection: but this is an erroneous view. It is from the greater sensibility of the upper orifice of the stomach than any other part of it, that we are most sensible of uneasiness in that region: but irritability of the whole, or of any other part of the organ, and perhaps of the adjoining organs, as the pancreas, spleen, and liver, will often produce the same local pain; and, in some instances, it has been ascertained after death to have been occasioned by a schirrous, or some other, obstruction of the pylorus.

In the second variety, we find the pain or uneasiness somewhat less intense, but far more general; reaching, indeed, over the whole range of the stomach and epigastrium, accompanied with nausea and anxiety; and, by sympathetically affecting the general system, attended with coldness of the extremities, failure of strength, shortness of breath, and great tendency to faint, which continues till the system reacquires warmth and perspiration.

From the wider circumference of the affection, Hippocrates denominated it *periodynia stomachi*. It is distinguished in popular language by the name of *sinking heart-burn*.

The third variety is distinguished by a morbid increase in the quantity of the fluids secreted; and hence the peculiar symptom of an eructation, frequently in considerable abundance, of a thin, watery liquor; chiefly in the morning, after food has been abstained from for many hours, and the stomach has nothing in its cavity but its own fluids. Dr. Cullen has admirably described the disease; though he has singularly separated it to a great distance from dyspeptic affections, transferred it to another order, and erected it, apparently contrary to his own mode of reasoning, into a distinct genus. "It appears most commonly," says he (*First Lines*,

vol. iv., p. 13), "in persons under middle age, but seldom in any persons before the age of puberty. When it has once taken place, it is ready to recur occasionally for a long time after; but it seldom appears in persons considerably advanced in life. It affects both sexes, but more frequently the female. The fits of this disease usually come on in the morning and forenoon, when the stomach is empty. The first symptom is a pain at the pit of the stomach, with a sense of constriction, as if the stomach were drawn towards the back; the pain is increased by raising the body into an erect posture, and therefore the body is bended forward. This pain is often severe; and, after continuing for some time, brings on an eructation of a thin watery fluid in considerable quantity. This fluid has sometimes an acid taste, but is very often absolutely insipid. The eructation is for some time frequently repeated; and does not immediately give relief to the pain which preceded it, but does so at length, and puts an end to the fit." To this description it may be added, that, when the watery discharge is altogether insipid, there is merely an increased secretion of the fluids poured into the stomach, apparently in a thinner or more dilute condition; and that, when this discharge is of an acrid taste, the gastric or other juices, which exist simply and without food or other intermixture in the stomach at the time, possess an acidity in themselves; a fact, which closely connects pyrosis with cardialgia as a species, and readily reduces it to the rank of a variety under its banner. In the colloquial tongue of England, it is called *black-water*; in that of Scotland, *water-brash*, and *water-gulm*. It is the pyrosis of Sauvages, and many other writers.

Most of these varieties have sometimes returned periodically,* especially in the spring; and as their general causes and mode of treatment do not essentially differ, it is more convenient to consider them jointly than under detached heads. Dr. Perceval, of Dublin, in the manuscript comment with which he has obliged me on the nosology, ingeniously inquires, "Does it ever arise from an affection of the pancreas?" I think it likely that it does, from contemplating the structure and office of this organ; and we have various cases in which, after death, the pancreas has been found considerably enlarged.†

* Bartholin. Hist. Anat., Cent. iii., Hist. 50. Zacchus, Consil. N. 54, 98.

† Post mortem examinations demonstrate that this is occasionally the cause of pyrosis. An enlargement and schirrus of the pancreas have been found, says Dr. Francis, in cases where the patient has long suffered from this infirmity: he adds, that the disordered condition of this organ is also attended with great irritability of the stomach, the contents of which are ejected with great violence. These views are partially sustained by Dr. Sewall, of Boston, in his paper on the diseases of the pancreas.—(See New-Eng. Journ. of Med. and Surg., vol. ii.) The excessive drivelling of some inebriates who have indulged in the abuse of spirituous drinks, adds Dr. F., is in part at least to be explained by the altered condition of the pancreas, as demonstrated by autopsic examination.—D.

The remote causes then of the present species, under whatever variety it shows itself, which is chiefly regulated by the habit or idiosyncrasy of the individual, are indigestible food or other ingesta; and habitual and copious use of very cold or very hot beverages, but especially the latter; indulgence in spirituous potations; worms, hydatids, and insects or their larvæ; drastic purges; obstructed perspiration; repelled cutaneous eruptions; and bile depraved, or excessive in its secretion. Of the indigestible foods, the most common are animal fat, oil, butter, or cheese, eaten in excess; which last has produced a cardialgia that continued for three years.* The stones or kernels of fruits have often laid a foundation for the complaint, especially where they have remained, as they have occasionally been found to do, and particularly cherry-stones, for two, or even for three years, with little or no change whatever.† It occurs also, as already observed, not unfrequently as a sequel or symptom of some other affections.

All these causes have a direct tendency to produce imbecility of the stomach, especially a loss of tone, or weaker action in its muscular fibres; and a morbid condition of the fluids secreted by, or poured into it.

Acidity seems to be common to all its varieties; and this to such a degree that, as Dr. Darwin observes, the contents of the stomach, when regurgitated on a marble hearth, have often been seen to produce an effervescence on it.

The acid, according to the experiments of M. Perperes, is chiefly the acetous, and he has found, that not less than two ounces and six drachms of it have been produced by eight ounces of roasted chestnuts, an aliment that ferments in the stomach for an hour and a half; and is even then digested with great difficulty. In some cases, the formation of acetous acid seems to be favoured by the nature of the gastric fluid itself, which appears to be secreted in too dilute or weakly a condition for the purposes of digestion; on which account, the food, instead of being converted into chyme, runs readily into a state of fermentation, so that some persons cannot take either honey or sugar without producing this effect; while in others, the gastric juice itself, when first secreted, may possibly contain too large a proportion of the muriatic acid, which, according to the late valuable researches of Dr. Prout, is found in the stomach during digestion.

It is not improbable that the third variety, *cardialgia sputatoria*, may, in some instances, be produced by inactivity of the proper absorbents of the stomach. The experiments of M. Magendie show that, in a state of health, all fluids disappear from the stomach with great rapidity, in consequence of the urgency of their absorption, insomuch that a ligature on the pylorus does not in the least retard their vanishing.

* Paulini, de Nuce Moschata, sect. iii., p. 3. Eph. Nat. Cur., Dec. 11., Ann. v., app. 71.

† Bresl. Samml., 1725, i., p. 77. Gronen. Commerc. Liter., Nov., 1733, p. 189.

In applying to this disease the resources of the art of healing, it is obvious that our intention should be twofold : to palliate the present distress, and to prevent a recurrence of the paroxysms. The first may be obtained by small doses of opium, and sometimes by other antispasmodics, as the ethers and ammonia; and where acidity is unquestionable, by calcareous and saponaceous earths.* Lime-water, or acidulous alkaline waters, or the carbonates of soda and potash, magnesia and lime, have been almost the only ones that have hitherto been employed, or at least the others have not been submitted to a sufficient trial, and under a sufficient variety of modifications, to enable us to speak of them with accuracy. It is a common belief that chalk, with an acid in the stomach, produces an astringent, and magnesia a laxative neutral. This idea is doubted by Dr. Cullen;

* *Gastrodynia* and *gastralgia* are terms frequently used almost synonymously with *cardialgia*. In one form of *gastrodynia*, described by Dr. Barlow, of Bath, the disease is represented as depending upon a redundant and unhealthy state of the mucous secretions of the stomach and bowels. Hence, instead of endeavouring, in the first instance, to palliate the pain with opium or stimulants, he begins with active purgatives of calomel and colocynth, with or without the addition of tartarized antimony. When the costiveness is obstinate and habitual, he exhibits every night, or every night and morning, if necessary, colocynth, aloetic pill, or colocynth conjoined with henbane, two parts of the former to one of the latter. While aperient medicines are continued, some of the *mistura salina cardiaca* of the Bath Hospital Pharmacopœia is given, composed as follows:—

R. Sodæ Subcarb. ʒiiss.
Aq. Puræ Oviiss.
Acid. Sulph. dil. ʒj.
Confect. Aromat. ʒiij.
Spir. Ment. Pip. ʒiij.

"The foregoing quantities, thus combined, yield 324 grs. of sulphate of soda, 423 grs. of the subcarbonate remaining unaffected by the acid. Thus each ounce of the mixture contains but a few grs. of either salt; yet, insignificant as the dose may appear, it is not inert. When *gastrodynia* still goes on, after the secretions of the alimentary canal have been rectified, Dr. Barlow has found the oxide of bismuth the best auxiliary medicine, in the dose of five grains, with one of aloes, given three times a day, in conjunction with the cordial mixture. For some cases, spirit of ammonia is a useful addition; while for particular examples the camphire and cordial mixtures in equal parts; and for others, a blister to the scrobiculus cordis, are well spoken of."—(See *Cyclopædia of Practical Medicine*, art. *Gastrodynia*.) With these observations, delivered by Dr. Barlow, the practitioner may usefully compare those made by Jolly, in his account of *Gastralgie*, Dict. de Méd., &c., Paris, 1833. In *gastrodynia*, not apparently occasioned by any thing in the stomach, "you find tinct. of opium an excellent remedy. In the continued form of the disease, prussic acid will answer better; but I never saw it succeed, when it was given for immediate effect."—(Elliotson's Lectures.) In full habits, he advises bleeding, which he has often seen relieve *gastrodynia* at once. Stramonium he has also known cure *gastrodynia*, and, as not producing costiveness, is preferable to opium.—ED.

but it seems to have a foundation, and should regulate our practice. Chalk, however, when used in large quantities, and long persevered in, has an indisputable evil, which does not equally belong to soda or magnesia; and that is, its aptitude to form balls or calculi in some part of the intestinal canal; and thus produce a very troublesome obstruction, and occasionally colic. I have known various instances of this; and, in some cases, attended with alarming symptoms before the balls were dejected; many of which I have also known to be evacuated in masses of more than an ounce weight each. There is no evidence that an acid is found below the duodenum, and hence it is chiefly in the upper part of the alimentary canal, that these calculous concretions are impacted and agglutinated. Dr. Parr and some others assert, that an acid formed in the stomach certainly never enters the circulating fluid. It is indeed true, that we have no sensible trace of it in the course of the circulation: but the benefit which has lately been discovered, and which we shall have occasion to advert to more fully hereafter, of introducing magnesia into the stomach, in habits possessing a tendency to form calculi in the kidneys and bladder from a superabundant secretion of lithic acid, seems to show, that an acid principle, or base, still passes from the stomach into the circulation in certain cases, though too minutely divided to be detected by chymical tests; and that the introduction of magnesia into the stomach destroys or neutralizes it at the fountainhead.—(See ENTEROLITHUS and LITHIA.) M. Perperes, in taking off acidity from the stomach, unites the calcareous earths with a warm bitter; and recommends, as the medicine he has found most successful, columbo root with magnesia, in doses of ten grains of the former to twelve of the latter.

It is observed by Dr. Darwin that, as the saliva swallowed along with our food prevents its fermentation, considerable relief is sometimes derived from frequently chewing parched wheat, mastic, or a lock of wool, and swallowing the saliva thus procured.

Oleaginous preparations have also been employed, and in some habits apparently with success. In such cases, it is most probable that they act, first, by converting a part of the acid into soap; and next, by proving aperient, and thus accelerating the passage of the acid material into the intestinal canal. The complaint may also be palliated by mucilaginous substances, such as Spanish liquorice, or gum-arabic. In many cases, speedy and effectual relief is obtained by the simple and pleasant remedy of eating six or eight almonds.

Yet, where we have full proof of acidity as the exciting cause, there are few medicines we can more fully depend upon than soap; probably because in its decomposition it lets loose the oleaginous principle, which may in some degree obtund the pain, and at the same time unites its alkali with the acid of the stomach; thus neutralizing its acrimony, and forming a valuable aperient. "It is often," says Dr. Cullen (*Mat. Med.*, vol. ii., p. 400), "a more convenient

remedy than common absorbents or simple alkalis." If the pain be very severe, we shall much improve the beneficial operation of the soap by combining it with opium. This I have already mentioned as a valuable medicine in all the varieties of the disease; but it is peculiarly so in water-brash, or the third variety. The distinguished writer I have just quoted asserts, indeed, that he has found nothing but opium that will give it real relief: but this, he afterward adds, relieves only the present fit, and contributes nothing to the prevention of future attacks.*

It is hence necessary, in every case, to direct our view to the second intention I have pointed out: I mean that of preventing a recurrence of the paroxysm.

Now, this can only be done effectually by restoring the stomach to its proper tone; and hence the entire process we shall have to notice under *DYSPEPSIA*, forming the seventh species of the present genus, will here be found equally advantageous. The warmer bitters, the metallic oxides, and especially the oxides of zinc and bismuth, first mentioned by Odiër,† bid fairest for success. Of the bitters, one of the most elegant, as well as most effectual, is the extract of chamomile. The *nux vomica*, long since extolled by Linnæus, remains yet to be fairly experimented with in this country. It has the peculiar property of diminishing the sensibility, while it increases the irritability of the animal frame—a property of which I shall speak more at large when discussing the subject of *PARALYSIS*. It is said to have been given in doses of ten grains three times a day. But this I very much question, where the drug has been sound and genuine. In palsy I have never been able to raise it above seven grains, without making the head stupid and vertiginous.‡

Among the aromatics, many of the terebinthinate balsams will be found highly useful. The balsam of Gilead, and that of Mecca, *amyris Giladensis*, and *a. Opobalsamum*, were once highly extolled, and perhaps deservedly; but are too dear for common use. The Turks take eight or ten drops as a dose; but the quantity may be considerably increased. In some of the

* Among the means of affording prompt relief, ought to be mentioned hot fomentations to the epigastrium, and the use of the warm bath. Where tenderness on pressure is complained of, leeches are also frequently proper. If there be very fetid eructations, it is best to give an emetic; or, if this be not judged proper, the practitioner may try the effect of common acids, or two or three drachms of the solution of the chlorurets in ordinary use. Elliottson.—(See Med. Gazette, 1832-33, p. 659).—EDITOR.

† Odiër's practice of administering the oxyde (subnitrate) of bismuth, when first introduced, was quite popular, and Dr. Moore published a thesis on the subject; but this remedy is now fallen almost into disuse. The internal administration of charcoal, blended with a small proportion of pulverized myrrh, is recommended by many.—D.

‡ According to Professor A. T. Thomson, the *nux vomica*, in the form of powder, has been carried to the extent of fifty grains a day.—*Elements of Materia Medica*, vol. i., p. 336.

pharmacopœias, cubebæ, as much cheaper, have been ordered instead of the balsams.

The diet should consist of articles least disposed to ferment; as animal food generally, shellfishes, biscuits; and the drink be, small brandy and water, toast and water, lime-water, or most of the mineral waters.

SPECIES V. LIMOSIS FLATUS. FLATULENCY.

IMPAIRED APPETITE, WITH AN ACCUMULATION OF WIND IN THE STOMACH OR INTESTINAL CANAL; AND FREQUENT REGURGITATION.

It is supposed by Mr. Hunter, that air is occasionally secreted from the mouths of the secretants into certain cavities in which it is found: but, in the present instance, there can be little or no doubt that it is merely separated from the materials introduced into the stomach in the form of food, and tending towards fermentation. When the fluids, which are poured naturally into the stomach, are secreted in a state of health, they concur, and perhaps equally so, in checking fermentation. But when, from imbecility of this organ, or its consociate viscera, they are secreted in a dilute or other imperfect state, they lose their corrective power, fermentation rapidly commences, and the stomach is overloaded, distended, and sometimes ready to burst with the air, for the most part carbonic acid gas, that is hereby let loose; relief being only obtained by frequent *eructation*, or rejection upwards; *crepitation*, or rejection downwards, which the Greeks denominated *βορβορ*, as the Latins did *crepitus*; or its combining loosely with such fluids as may exist in the large intestines, where it often rolls about in an ascending or descending direction, according to the action of the diaphragm and abdominal muscles; sometimes with a rumbling sound, where the intestinal fluid is but small in quantity, and sometimes, where it is considerable, with a gurgling noise, like air rushing into a bottle as the water contained in it is poured out; and hence by the Greeks denominated *borborygmus*. We have, in consequence, the three following varieties, under which this species presents itself to us:—

- | | |
|----------------|---------------------------------------|
| α Borborygmus. | With frequent rumbling of the bowels. |
| β Eructatio. | With frequent rejection upwards. |
| γ Crepitus. | With frequent rejection downwards. |

The quantity of air separated in the manner just described is sometimes prodigious, and may amount to an eructation of many hogsheds in an hour. Nor need we be surprised at this; for, by the experiments of Dr. Hales, it appears that a single apple, during fermentation, will give up above six hundred times its bulk of air; while many of the vegetable materials introduced into the stomach possess far more venosity than apples.

Flatulence, under one or other of the forms

now enumerated, is often found as a symptom of other diseases; especially in dyspepsy, cholera, colic, hysteria, and hypochondriasis. But there is no doubt that it occasionally exists by itself, and is strictly idiopathic, occurring after the deglutition, and even enjoyment, of a full meal, without any other symptom of indigestion, and ceasing as soon as the process of digestion is completed.

[Flatulence produces various feelings of distress, according to the part of the alimentary canal in which the wind is generated, or pent up. When it is copiously generated in the stomach, and is not expelled by eructation, it gives rise to all the distressing consequences always resulting from great distention of that organ. In some instances, severe pain is excited by the simple extension of its fibres, or their spasmodic contractions. In others, especially in hysterical habits, the adjoining organs are considerably affected by the pressure of the distended stomach; whence great anxiety and oppression are felt in the chest from the impediment to the free motion of the lungs and heart; the respiration becomes laborious and difficult, with a sense of suffocation, and the action of the heart intermits, or violent palpitations occur.

When the bowels are inflated, a sense of uneasiness is experienced, with a rumbling or gurgling noise. Sometimes colic is an attendant on the complaint, and sometimes the whole abdomen is enlarged by the general distention of the intestines with air, accompanied with constipation. When this distention has been of some duration, a degree of paralysis of the muscular fibres of the bowels is produced; their power of expelling the wind is lost; the skin of the belly becomes as tight as the parchment of a drum; and the patient falls into a state of great emaciation. This disease is called *tympanites*.]

A very common cause of flatulence is drinking a large quantity of some cold fluid while the system is labouring under great heat. Another is eating raw vegetables, cucumbers, radishes, salads, &c., or cabbages and other vegetables not duly boiled.

Infants are peculiarly subject to this affection, from the natural delicacy of the stomach, and particularly when brought up without their natural sustenance, and upon food which requires more labour of the stomach to digest. In many cases it must necessarily be combined with acidity; for this, as already observed, is a general effect of impaired action in the chylic viscera; and when both these causes concur, the infant will also be tormented with severe gripings and great irregularity in the bowels; a distressing and watery diarrhoea; or an obstinate costiveness; and sometimes with both in succession. Essential oils, absorbent powders, and aperients, may palliate the symptoms, but the best cure will always be found in a healthy breast of milk.

Hypochondriacs, and others of weak digestive power, are very apt to acquire a habit of eructing; and are perpetually striving to throw

up wind from the stomach in an expectation of relieving themselves from the elastic vapour with which they seem to be bursting. It was observed by Dr. Darwin, that when people voluntarily eject carbonic acid gas from their stomach, the fermentation of the aliment is accelerated; just in the same manner as stopping the vessels which contain new wines retards their fermentation, and opening them again quickens it. [This idea, applied to the case of flatulence, may be ingenious; but probably it will never persuade a single patient to repress his endeavours to relieve himself by eructations. The reality also of the ill effects of the practice is doubtful.] If cardially attend, the air is sometimes eructed with a sense of burning so violent as to make the patient imagine he is actually, like a volcano, belching forth flames and fire from his entrails.

There are some cases on record, in which persons appear to have a power of distending the stomach and abdomen to an enormous size at pleasure; and advantage has been taken of this by one or two female impostors, who, for particular purposes, have hereby pretended to be pregnant, and have succeeded by such an imposition. But a distention of this kind does not belong to the disease before us.

The cure in this species, as in the last, depends upon giving tone to the muscular fibres of the stomach and intestinal canal; and hence the plan laid down already, and the course to be described under dyspepsy, will have the greatest chance of success.

Emetics have occasionally been recommended with a view of giving a change to the action of the stomach; but they are of doubtful efficacy. They have been of great service, however, incidentally, by discharging some lurking body which has itself been a chief cause of the disease. In this manner, worms have at times been thrown up; and at times also morsels of indigested fruit or other materials, as plumbstones, or fragments of a pear or apple.—(*Riedlin, Lin. Med.*, ann. iv. v.)

The disease may be palliated by an innumerable host of carminative plants, which vary in their several effects according to the variety of the idiosyncrasy, or the actual state of the stomach. The verticillate order affords an abundant stock, from which we may select at pleasure; as marjoram, thyme, rosemary, lavender, spearmint, peppermint, and pennyroyal; the aroma of all which resides chiefly in the leaves or calices. The coniferous order offers, perhaps, nearly as many, including the terebinthinate and juniper tribes; but of less activity than the preceding, except in the instance of the essential oil of juniper, the pleasantest of all the turpentine family. The medicinal virtue of both these orders is that of camphire, which they all contain very largely, especially the peppermint, as shown by the experiments of Gaubius.—(*Adversar.*) The pungency of this plant, however, is so acrid as to exhaust the sensibility of the nerves of the tongue and palate for a moment, and hence to give a feeling of coldness in succession to that of heat. Its best form is

what is called its essence, which, as conjectured by Dr. Cullen, appears to be nothing more than its rectified essential oil dissolved in spirit of wine. On account of the acridity of this plant, it is less valuable, as well as less palatable, than spearmint; which last acts better, and is more pleasant to the taste, when fresh in infusion than when distilled.

The umbellate order affords also a rich variety of carminatives, whose virtue, with a few exceptions, resides almost entirely in their seeds. The aroma of several of these is very pleasant, as the coriander, anise, and dill; while, in a few, as in the fennel, it approaches the nauseous smell and taste of the fetid gums. This, however, is an advantage in flatulencies occurring in hysteric or other nervous habits.

To these may be added many of the aromata imported from hot climates in very different forms; as barks, roots, berries, pods, and seeds, particularly ginger, cloves, cardamoms, cinnamon, pimento, pepper, and capsicum. Like those already noticed, they all owe their virtue to an essential oil, in whatever part of the plant such virtue may reside: but several of them have likewise some other property, which may render them more or less eligible in different cases. Generally speaking, the stimulants we are now contemplating are more strictly entitled to the name of cordials than the umbellate or verticillate plants; for, by exciting the nervous energy in a greater degree, they increase the action of the heart, and quicken the pulse. And hence, when the circulation is weak and languid, they have an advantage over the preceding; but when the pulse is already too frequent, they should be abstained from.

To this general remark, however, there may be one or two exceptions. Newmann and Gaubius, reasoning from the general use of pepper among the Hindoos and Javanese without any particular marks of excitement, have contended that it produces less effect on the sanguiferous system than many other carminatives; but this may be resolved into habit. Dr. Lewis, from some less obvious train of argument, came to a like conclusion in respect to ginger; which to many is as heating as any of the spices whatever. But it seems generally conceded, that nutmeg is entitled to the character of a sedative and even of an hypnotic; and hence, where flatulence is accompanied with great irritability, it becomes peculiarly valuable. Bontius speaks of this influence as a matter of frequent occurrence in the East Indies, and one which had often fallen under his own observation; and in the German Ephemerides (Dec. ii., Ann. ii., Obs. 120) we have an account of some extraordinary effects on the nervous system, occasioned by swallowing a large quantity of this spice. To which I may add the following confirmatory evidence of Dr. Cullen, derived from his own practice. "A person by mistake," says he, "took two drachms or a little more, of powdered nutmeg. He felt it warm in his stomach, without any uneasiness; but in about an hour after he had taken it, he was seized with a drowsiness, which gradually increased to

a complete stupor and insensibility; and not long after he was found fallen from his chair, lying on the floor of his chamber, in the state mentioned. Being laid abed, he fell asleep; but waking a little from time to time, he was quite delirious; and he thus continued alternately sleeping and delirious for several hours. By degrees, however, both these symptoms diminished; so that, in about six hours from the time of taking the nutmeg, he was pretty well recovered from both: although he still complained of headache and some drowsiness, he slept naturally and quietly through the following night, and next day was quite in his ordinary health."*

Many of the foregoing remedies have often been combined with the oxyde or nitrate of bismuth; and as they have commonly been more successful with such adjuncts than when given alone, these preparations of bismuth itself may be regarded as a useful carminative. They are especially serviceable when the flatulence is chronic, and accompanied with distressing pain.

Before quitting this subject, I will just notice two other remedies for flatulence, because they not only afford benefit at the time, but, by their tonic virtue, have some tendency to correct the disorder radically.

The first of these is the tincture of *aspalathus canariensis*, the rosewood, or *Rhodium lignum* of the old writers. This shrub readily yields its fragrant essential oil to rectified spirit; and the tincture is commonly made by macerating four ounces of the wood in a pint of the spirit. It proves a warm, balsamic, and pleasant cordial, in doses of from twenty or thirty drops to a drachm.

The second remedy I have alluded to is the ethereal oil, as it is now called, or the *oleum vini*, as it was called formerly, which is found in the residuum of sulphuric ether, and is easily made to float on the surface by the addition of water. It has a strong, penetrant, and aromatic odour, and readily dissolves in alcohol and ether. It is powerfully sedative as well as cordial, and is sufficiently known to be the basis of Hoffman's celebrated anodyne liquor. In the Pharmacopœia of the London College, this anodyne is imitated in the compound spirit of ether, the only preparation in which the ethereal oil is an ingredient. For the purpose I am now speaking of, however, it should be dissolved, and in double the quantity contained in the preceding preparation, in the aromatic spirit of ether. [Flatulence admits of being relieved by the generality of stimulant and antispasmodic medicines, such as assafoetida, the strong smelling gums, ammonia, opium, ether, &c. Together with internal remedies, Dr. Darwin applied fomentations to the epigastric region, and Dr. Whytt, stimulating liniments.]

* Hence, Dr. Cullen cautions us against giving this aromatic in apoplectic or paralytic cases. The use of the nutmeg, as a medicinal agent, dates from the time of Avicenna. "The volatile oil is sometimes ordered in the form of an oleo-saccharum in flatulent states of the stomach and intestines." &c.—See Dr. A. T. Thomson's *Elements of Materia Medica*, &c., vol. i., p. 226.

SPECIES VI.

LIMOSIS EMESIS.

SICKNESS OF THE STOMACH.

REJECTION OF THE CONTENTS OF THE STOMACH,
OR TENDENCY TO REJECT.

A DISPOSITION to regurgitate, or even the act of regurgitation itself, is not necessarily a morbid affection; and to render it such, it must be combined with the symptoms forming the generic character, which, though not specifically repeated, are always supposed to constitute a primary part of the description; and which, in the present genus, is an "impaired, excessive, or depraved appetite." Thus a regurgitation of food is natural to all grazing quadrupeds possessing complicated or numerous stomachs, as the sheep and ox; and it constitutes what is called rumination, or chewing the cud; the inverted action taking place at the will of the animal, and the food being thrown back from the first stomach, or paunch, into the mouth, for the purpose of further mastication. There are instances of rumination, or a simple voluntary regurgitation of the food into the mouth, among mankind. The German writers upon this subject are numerous, and their collections of cases abundant. But one of the best examples on record is that given by Dr. Slare. —(*Phil. Trans.*, vol. xvii., 1690–3.) The subject was an adult man, in good general health; the rumination regularly took place about a quarter of an hour after eating, at which time the food felt heavy in the lower end of the œsophagus. If he did not ruminate at the proper time, he soon became languid and sick.

It is a question that has raised much controversy, which are the parts chiefly concerned in exciting the stomach to vomit? Haller, and the physiologists of his time, were wont to refer us to the stomach itself. It was the opinion of Mr. John Hunter, that this action is performed alone by the muscles surrounding the stomach, and that the stomach itself is at the time as passive as the lungs in expiration.*

For the determination of this point, M. Magendie lately instituted a series of highly curious

experiments, of which a brief account has been given in the *Physiological Proem*. From these it would appear, that, in nausea, the action is confined to the organ of the stomach alone, or perhaps in conjunction with the œsophagus; that retching is produced by the contraction of the abdominal muscles, and rejection by the contraction of the diaphragm alone, or in conjunction with that of the abdominal muscles; and, consequently, that an emetic does not cause vomiting by irritating the fibres or nerves of the stomach, but, as suspected by Mr. J. Hunter, by means of absorption and irritation of the nerves of the muscles that surround the stomach; or rather by the stimulus produced on the brain, instead of on the stomach, and especially transmitted to these muscles.*

These experiments, however, have since been called in question by M. Portal, as not conducted with sufficient strictness, and leading to conclusions too generally and too hastily drawn. He maintains that vomiting commences by a particular action of the stomach, and is then aided and continued by the action of the abdominal muscles and of the diaphragm: but that, in many cases, this auxiliary assistance is by no means necessary; since, according to his experiments, vomiting may be produced in the stomach when the abdominal parietes have been removed.† And, consistently herewith, Dr. Parr informs us (*Dict. Append.*, p. 101), that the diaphragm "has been wounded, torn, and its apertures enlarged, so as, either by laceration or dilatation, to admit of the passage of the stomach, or a part of the colon, into the thorax, without any uncommon symptoms." [In the example of incessant vomiting, recorded by Gondret (*Magendie, Journ. de Physiol. Expér.*, tom. i., p. 280), where the coats of the stomach were found after death indistinguishably blended together, and converted into a homogeneous scirrhous mass, it may be doubted whether the organ itself had any share in the rejection of its contents. In the enormous dilatations of the stomach which sometimes fill the greater part of the abdomen, without any disease or obstruction of the pylorus, some cases and dissections of which are well described by M. Andral, it is easily conceivable, how a slight pressure produced on the stomach by the abdominal muscles, might occasion the frequent vomiting by the partial expulsion of its contents, notwith-

* It has been already explained in the *Physiological Proem*, that, in vomiting, the pharynx is elevated and the glottis shut; and that, as soon as the contents of the stomach have been expelled, the pharynx again falls, the glottis opens, and a full inspiration takes place.—See Professor A. T. Thomson's *Elem. of Materia Medica*, vol. ii., p. 187. This work contains many judicious reflections on the views given of this subject by Magendie, Sir C. Bell, Dr. Marshall Hall, and others. The closure of the larynx, and the retention of air in the lungs, according to Dr. Marshall Hall and Dr. A. T. Thomson, prevent the ascent of the diaphragm into the chest; and the pharynx being drawn up, as in the act of deglutition, opens the cardiac orifice of the stomach, and forms with this viscus one continuous cavity. This fact explains the remark of Magendie, that, "during the state of nausea, which preceded vomiting in some of his experiments, air was drawn into the stomach." Dr. Thomson's explanation differs from Dr. Hall's, chiefly in representing the diaphragm as fixed, and not floating and loose.—Ed.

* If emetics always acted by their local stimulating influence on the coats of the stomach, it might be expected that the time which elapses between the taking of an emetic substance into the stomach and its operation, would be much shorter than it is; and Professor A. T. Thomson is of opinion, "that, in every instance, unless from a mechanical irritant, the emetic substance must be taken into the circulation, before vomiting is induced. We know that when tartar emetic is introduced directly into the circulation,—into a vein, for example—it produces vomiting sooner than if it had been swallowed."—*Op. et vol. cit.*, p. 188.

† *Mém. de l'Institut Royal de France*, Mai 19, 1817. *Mémoires sur la Nature et le Traitement de plusieurs Maladies*, tom. iv. Paris, 1819. 8vo.

standing the paralytic state of its own muscular fibres; the cause to which this author, with great plausibility, ascribed its prodigious dilatation.—(*Op. Cit.*, tom. ii., p. 248.) This, however, was a state of disease; and by no means amounts to a refutation of the doctrine, that, under ordinary circumstances, the stomach itself, as well as the muscles of respiration, assists in the expulsion of its contents. The same observation applies to the curious malformation recorded by Drs. Graves and Stokes (*Dublin Hospital Reports*, vol. v.), in which, though the stomach was lodged in the thorax completely above the diaphragm, continual vomiting attended the patient's illness. This case, with other facts bearing on the different views entertained of the question, seems to justify the conclusion which the editor arrived at in the *Physiological Proem*.]

Doubtless, a close connexion and sympathy exist between the stomach and its surrounding muscles; and hence, let the irritation commence in whichever organ it may, it will be instantly propagated to the other. We have the same proofs of sympathy in the stomach, the ileum, the œsophagus, and the fauces. And we can evidently trace the retrogressive action commencing in different diseases and under different circumstances, sometimes in one of these organs, and sometimes in the other. And we can sometimes, moreover, see this action limited to a particular part; sometimes running through a certain length of the chain, and sometimes through the whole. The idea of swallowing a nauseous dose of medicine, or an irritation of the fauces by a hair, will often excite a retrograde action in the œsophagus alone: a discharge of wind in cardialgy, or of a small portion of acid, or oil, or any other substance floating on the surface of whatever may be contained in the stomach, seems to excite the fibres of the cardia alone, and they are expelled by its simple and unassisted effort, producing a single act of eructation or belching. The sulphates of zinc and copper, and perhaps all the metallic emetics, act unquestionably upon the fibres of the stomach generally and primarily; and probably all the ipecacuanhas, whether of the psychotria, the callicocca, or the viola genus, are first absorbed, as asserted by M. Magendie, and then produce vomiting by irritating the fibres of the surrounding muscles. Seasickness, and various affections of the head, apparently act in the same manner; and the contractile and inverted action only takes place after a paroxysm of intolerable sinking and lan-

guor. In ileus, the retrogressive movement, commencing in the bowel which gives rise to the name of this disease, runs with great violence through the whole chain of the alimentary canal; inasmuch that medicines introduced into the rectum are rejected by the mouth. In few words, then, "vomiting," to adopt the language of Sir C. Bell, "is an action of the respiratory muscles, excited by irritation of the stomach;"* or, as we should add, of those muscles themselves.

Sickness of the stomach occurs under different forms: the three following are the chief varieties:—

- | | |
|--------------|---|
| a Nausea. | Tendency to reject, but without regurgitation. |
| Loathing. | |
| β Vomiturio. | Ineffectual effort to vomit. |
| Retching. | |
| γ Vomitus. | Act of vomiting, or rejecting from the stomach. |
| Vomiting. | |

Sauvages and Linnæus regard the first and third of these varieties as distinct genera of disease, and even arrange them as such. This appears highly incorrect; for, if minutely examined, they will be found, in every case, to be little more than different degrees or modifications of the same affection, produced by a greater or less inversion of the peristaltic motion of the stomach and œsophagus, whatever be the cause of such inversion, and allayed or overcome by the very same means. Where the stimulus, and consequently the degree of inversion, is slight, the effect is confined to nausea; if beyond this, the nausea becomes retching; and then the retching becomes vomiting. They may, indeed, exist separately; for the cause may be of a kind or strength sufficient to throw the stomach at once into a state of violent inversion, and, consequently, to produce vomiting without the common, intermediate changes; as in the case of various metalline emetics, sympathetic irritation from pregnancy, or the swallowing putrid vapour: while, on the contrary, minute doses of squills, or ipecacuanha, or any other cause that produces but a slight degree of action, will excite nothing more than nausea, or the first stage alone of the inverted action upon which the general affection depends.

It is nevertheless curious, and of great importance, to observe the different and opposite effects produced on the animal frame by these two stages of one and the same disease. Nausea lowers the pulse, contracts the small vessels, occasions cold perspiration, severe rigours, and trembling, and diminishes, as long as it lasts, the action and even the general powers

* Experiments on the structure and functions of the nerves.—Phil. Trans., 1822, p. 406. Sir Charles Bell qualifies this theory by observing, "That when the stomach is excited to vomiting, there is consent of the abdominal muscles, by which they are brought into violent spasmodic action; not alternating in their action, as in the motion of respiration, but acting synchronously, so as greatly to assist in compressing the stomach;" but "at the same time, the action of these muscles, however forcible their contraction, cannot alone cause vomiting; nor has this action any tendency to produce such an effect on other occasions, in

which the utmost contraction of the diaphragm and abdominal muscles is required for the compression of the viscera." Vomiting is not, therefore, simply an action of the respiratory muscles. Dr. Marshall Hall's explanation of the mechanism of vomiting is this:—"The contents of the thorax and abdomen are subjected to the sudden and almost spasmodic contractions of all the muscles of expiration, the larynx being closed, so that no air can escape from the chest, and the two cavities being made one by the floating or inert condition of the diaphragm."—*Ed.*

of life. The act of vomiting, on the contrary, rouses rather than depresses; puts to flight all the preceding symptoms, and restores the system to itself.* There are few persons so debilitated as not to bear vomiting, but many who would sink under nausea. It is obvious, therefore, that these two different states of the stomach may be employed as powerful instruments in attacking a variety of general, and even of remote local diseases; this organ being justly considered as the common centre of sympathy, and producing opposite results, according as it is excited to different modes or degrees of action. As nausea diminishes the action of the system generally, and particularly that of the small vessels, it has been often had recourse to with success in inflammation of various organs, particularly of the eyes and lungs; as it has also on the approach of the first fit of intermitting fevers, or the accession of those of a continued type, which threaten a considerable degree of violence. Full vomiting, by augmenting the general action, and consequently giving great additional energy to the absorbent system, has also been very advantageously employed to remove inflammation, though in a different manner; and particularly inflammation of the suppurative kind. Orchitis and purulent ophthalmia have often yielded to it as a charm; and we have various instances, in which the fluid of extensive abscesses has been hereby carried off in a few hours. From the pressive violence of the action, it has also been highly beneficial in many cases of obstruction, or chronic torpidity: and hence its occasional utility in amaurosis and caligo; and still more so in congestions of the liver and other abdominal viscera.†

* In vomiting, or the forcible ejection of the contents of the stomach, the influence of the emetic is carried beyond this organ; for, the secretion of the liver being forced into the duodenum, and passing from that into the stomach, in the act of straining, is also ejected. Besides, by the same act, all the abdominal viscera are compressed; and by a repetition of this cause, the blood is propelled more forcibly through these viscera, and the secretion of the fluids thereby increased and altered. In particular, the blood is propelled through the vena portarum; and, consequently, the secretion of bile is both augmented in quantity, and altered in quality: the gall-bladder and biliary ducts are emptied; the pancreas and spleen are also affected; and the action of the kidneys promoted. The pulmonary system likewise feels the influence on the whole constitution; and the circulation through the lungs is accelerated. But these organs are partly affected by their sympathy with the stomach, and not wholly by the mechanical action of vomiting. Vomiting excites the secreting and exhaling vessels of the lungs, and hence emetics hold a place among expectorants. They produce a change in the secreted fluids of the stomach itself, not only bringing about the evacuation of any superabundant acid, but so altering the action of the secreting vessels, that for a time all trace of acid disappears. See Dr. A. T. Thomson's *Elem. of Materia Med.*, vol. ii., p. 194; a work abounding in valuable matter.—Ed.

† During the action of vomiting, as Professor A. T. Thomson observes, the blood is propelled, not only more quickly through the arteries, but

As different emetics, however, produce not only a different action on the stomach, but also on the system at large or different parts of it, they are by no means to be used indiscriminately, but in reference to the particular object we have in view. This difference of effect depends upon the peculiarity of their *emetine*, as the French writers denominate it, or emetic principle, of which we require further instruction than has been obtained at present; though the experiments of MM. Magendie and Pelletier have given us some information concerning this principle, as it exists in the brown *ipeacuanha* (*psychotria emetica*), the gray (*callicocca ipeacuanha*), and the white (*viola emetica*). [When given in doses of from a grain to three grains it produces full vomiting; and, as none of the other principles of *ipeacuanha* root produce this effect, there is no doubt that its emetic power is owing to the *emetine*, a principle contained in the roots of some other plants, besides those of *ipeacuanha*.]—(See Thomson's *Mat. Med.*, vol. ii., p. 209.)

The *ipeacuanhas*, however, though possessing some diversities of power, concur in operating very generally upon the skin, at the same time that they excite the stomach; increasing, in a slight degree, the discharge of mucus from the lungs, and adding a little to the peristaltic motion of the bowels. The antimonial emetics, in a full dose, act more violently upon the stomach, bowels, and skin, but less upon the mucous secretions. While in small doses, the nausea they produce is accompanied with the most deadly languor, and with an atony, that, in numerous cases, has been succeeded with more mischief than any degree of benefit that could have been proposed by their use. "Many in this manner," says Dr. Perceval, of Dublin, in his manuscript remarks on the volume of Nosology, "have sunk under the nauseating doses of emetic tartar, employed, upon the hypothesis of Dr. Cullen, in low fevers. The heart of a frog is so torpidified by this antimonial, as not to be excited by galvanism, which is not the case with opium. The fraction of a grain of tartar emetic, in a gouty habit, subject to melana and palpitation, produced an alarming delirium. In the same subject, a similar effect attended the use of other antimonials."*

also through the veins. Thus, it is more generally and equally diffused; and, of course, local determinations and congestions are removed. He doubts whether emetics really quicken the action of the absorbents, and is inclined to believe that the impulse communicated by them to the capillaries, has the effect of lessening deposition, and, as the process of absorption goes on at its ordinary rate, collections of fluids, tumours, and thickenings of membranes disappear after the operation of emetics.—Op. cit., vol. ii., p. 195. This latter theory is different from what is commonly entertained.—Ed.

* Dr. A. T. Thomson considers *ipeacuanha* preferable in every instance, in which the powers of the stomach are required to be maintained, and yet vomiting is indicated; and, in cases of chronic diarrhoea, there can be but one opinion as to the superiority of *ipeacuanha* over tartar emetic.

The squill and seneka* root act very generally; proving not only emetics, but cathartics and expectorants. The asarum, which was once extensively employed for vomiting both in its root and leaves, at the same time that it inverts the stomach, acts powerfully on the olfactory nerves, and becomes a pungent emetic. It is hence by far the best emetic we can select in affections of the eyes, and several species of cephalæa. Hot water operates only as a simple stimulant to the stomach; and hence, unless there be other irritants in its cavity, rarely takes effect till the stomach becomes distended, and the nervous fibres of the pylorus are inordinately excited by the quantity swallowed. If, however, we infuse in the hot water a certain portion of horseradish, mustard-seed, the root of mezereon, or a handful of chamomile flowers, we increase its stimulant power, and a much smaller quantity is sufficient. And it is probable that all these substances act, in like manner, as simple stimulants alone; for, in small doses, they tend rather to take off, than to excite sickness. There is little doubt that air acts in the same way; for some persons, as M. Goss, of Geneva, by swallowing and distending their stomach with air, are at any time able to discharge its contents. The sulphates of zinc and copper, and the more powerful preparations of antimony, are probably simple stimulants also, but of a high degree of activity. They act on the stomach almost as soon as they are introduced; and hence are peculiarly eligible for a rapid expulsion of poisons that have been taken inadvertently. If taken, however, in too large a dose, they become quite as mischievous as any poison they are intended to remove; for they prove violently corrosive to the coats of the stomach, and excite hæmatemesis, or vomiting of blood.† There are some of the alkaline salts that act in the same manner when taken in excess, and throw not only the stomach, but other parts of the system, into violent spasmodic motions. Two ounces of nitre were taken by mistake for one ounce of Epsom salts. An almost incessant vomiting for two days was the result, accompanied with a copious discharge of grumous blood from the excoriated mucous membrane of the stomach; notwithstanding that very large quantities of warm water were repeatedly drunk, and alternated with equal quantities of gruel and mucilage of gumarabic,

When deleterious effects arise from over-doses of ipecacuanha, or emetina, the best remedy is infusion of galls, which, by forming an insoluble precipitate with the emetina, renders it inert.—Op. cit. vol. ii., p. 214, 215.—Eh.

* Seneka, or rather senega, root, is highly commended as one of the most certain emmenagogues, by Dr. Chapman, Professor of Materia Medica in the University of Pennsylvania.—Eh.

† This remark must be taken in a limited sense; the vitriolic emetics, particularly those composed of the sulphate of zinc, may be used in doses of two, three, or even four drachms, without particular injury to the stomach, or to the mucous membrane of the intestinal tube. They generally excite great thirst, which must be allayed by the free use of bland mucilaginous drinks.—D.

to defend the surface of the stomach by an artificial mucilage. The patient recovered, but was long afterward subject to chronic spasms, resembling chorea.—(Buller, in *Edin. Med. and Surg. Journ.*, No. 53, p. 34.)

The ipecacuanhas, and, indeed, most of the preceding emetics, excite vomiting as effectually by being introduced into the bloodvessels, and consequently exciting the abdominal muscles through the medium of the brain, as by being conveyed into the stomach. But there are some articles that will produce this effect on being applied to the surface of the epigastric region, or the hypochondria alone; as the oil of croton, tobacco, and, what we should far less expect to possess such activity, the leaves of groundsel beat up into a cataplasm. Mr. Stedman, of Kincross, who, I believe, first published an account of this power in both plants (*Edin. Med. Essays*, vol. ii., art. 5), availed himself of it as a remedy for agues, and parabsmic tumours of the liver.

As the stomach is the common centre of sympathy, it is not to be wondered at that nausea, or sickness, should be a symptom common to a variety of diseases, seated in organs more or less remote from itself. And hence we find it occurring in colic, cholera, stone, the accessions of fevers, repelled gout, and various affections of the head.

The last is, indeed, a very frequent, perhaps the most frequent, of all the sympathetic causes whatever; for nothing can disturb the regularity of the sensorial function without disturbing the stomach; and hence sickness is sure to follow oppression of the brain, whether produced internally by hanging, drowning, or apoplexy; or externally, by a fracture of the cranium accompanied with depression. A severe jar of the brain, as in the case of concussion, even without extravasation, is certain of exciting the same effect. Nay, any slighter motion to which the head has not been accustomed, as that of moving it rapidly from shoulder to shoulder in a half rotary direction, accomplishes the same purpose. And hence we see the reason of the vomiting induced by running, or riding a horse round a small circle; by the act of swinging, or riding backward in a coach; and all the languor and deep regurgitation of sea-sickness. The living frame, however, has a most wonderful instinctive power of accommodating itself to circumstances; and hence, by habit, we are enabled to undergo the new motion without any inconvenience to the sensorium, and consequently without any sickness of the stomach. And this power of accommodation is so considerable, that we have numerous instances of extensive depressions, and even of bullets and other foreign substances lodged in the brain, which, though at first productive not only of incessant sickness, but of the most dangerous symptoms of compression, have by habit been borne without any evil to this organ; and hence, also, without any disquiet to the stomach.

In all these cases, however, the brain must still retain a certain degree of excitability: for, if this be entirely or very nearly lost, neither the

muscles surrounding the stomach, nor even the stomach itself, possess energy enough to produce an inversion of this organ. Hence, in an extreme state of apoplexy, or asphyxia, there is no vomiting whatever, nor is it possible to excite it in the profuse and sudden exhaustion of the nervous power which follows upon swallowing large doses of the *atropa belladonna*, and various other narcotics; in combating the effects of which, fourteen grains of tartarized antimony have been administered to no purpose. "Now, if, in such a case," says Dr. Paris, "a copious draught of some vegetable acid be given, the emetic will be more likely to succeed." And, agreeably with the principles just laid down, "here, then," says he, "we perceive that the brain, being paralyzed by a narcotic poison, is unable to lend its aid to the muscles requisite for the operation of vomiting, until its energies are restored by the anti-narcotic powers of a vegetable acid."*

In an affection resulting from such an infinite variety of causes, no one remedy or even plan of treatment can apply generally. Sympathetic sickness can only be radically removed by removing the idiopathic disease upon which it is dependant, though it may often be mitigated when very distressing, and the primary disorder is likely to be of long standing. The best palliatives, in most cases of this kind, will be found in carbonic acid gas; the saline draught, as it is called, in a state of effervescence, whether made with lemon juice, or as first proposed by Riverius, with sulphuric acid; the more grateful carminatives; and small doses of opium.†

* Pharmacologia, p. 152, 5th edit. 1822.

† When long-continued or frequent vomiting seems to depend upon morbid irritability of the stomach, the hydrocyanic acid, in doses of two or three minims three times a day, is an excellent medicine. The following case, related by Dr. Elliotson, exhibits the efficacy of this remedy. Eliza New had been ill five months, and had vomited every thing she had taken during fourteen days. She had been in a state of amenorrhœa for two months, and complained of pain across the epigastrium, and over the whole abdomen. Her tongue showed no feverishness; there was no thirst; no heat in the stomach; no heat in the throat; neither was there tenderness on pressure on any part of the abdomen; nor was the pulse accelerated. Under these circumstances, Dr. Elliotson inferred that it was not a case of inflammation. The patient took the hydrocyanic acid as above directed, without any other medicine, or even being restricted to low diet; her vomiting ceased, and, in a fortnight, she was discharged from the hospital with her health re-established. When there is an affection of the stomach, Dr. Elliotson advises the practitioner to consider, in the first place, whether there be inflammation or not; for, if there be inflammation, the hydrocyanic acid will not cure it; the case must be treated like inflammation of any other part of the body. But, if no inflammation can be detected, nor any cause for the vomiting in any other parts (as irritation in the intestines, the kidney, the womb, and ten thousand distant causes), then the hydrocyanic acid will relieve the vomiting better than any other medicine. As an anodyne, Dr. Elliotson has not generally found it of the least use, except in cases of pain of the

When the stomach is overloaded, or irritated by bile or any other material that sits uneasily, the offending matter must be first discharged, and then the stomach restored to its proper tone and action by some aromatic cordial, or, if necessary, by narcotics. Food should at first be given in the smallest quantity, and of the lightest kind. A little toast and water alone, taken in small sippings, or a small spoonful of brandy and water, with a single morsel of sopped biscuit, will often sit easy when nothing else will remain; and gradually solicit the stomach to a healthful re-action. Stimulant cataplasms applied to the epigastrium are also frequently serviceable.

When the sickness proceeds from a chronic debility of this organ, the lighter and warmer bitters, as the infusion of orange-peel, cascarilla, or columbo; or, where a more active stimulant is necessary, that of leopard's bane (*arnica montana*) may be found useful. The cinchona [except in the form of the sulphate of quinine dissolved in the compound infusion of roses] rarely agrees with the stomach. The oxides of zinc and bismuth are frequently useful. Sea-sickness* is only to be cured by habit: yet it has often been rendered less distressing by small

stomach. He declares that he has frequently seen vomiting, which has lasted for months, cease on the exhibition of the first dose of this medicine; though, he admits, that some cases of spasmodic vomiting will not yield until it has been tried for a week. He also expresses his belief, that it will prove unavailing unless the distinction be made between the existence of inflammation, and the influence of distant causes on the one hand, and mere morbid irritability of the stomach itself upon the other. He reminds us, that hydrocyanic acid is an exceedingly powerful medicine, and cannot be given in so large a dose when the stomach is empty, as when it is full. If three drops can be given three times a day after meals, it certainly will not be right to give more than one or two drops when the stomach is empty. To avoid all confusion, he thinks it best always to give it after meals, and to begin with one minim diluted with water, or an aromatic water. In the course of a day, if no unpleasant effect be produced, the dose may be increased to two minims; and on the third or fourth day, to three minims; and so on until the desired effect, or some inconvenience, is felt. Although it will relieve the vomiting arising from mere morbid irritability, it will, if given too freely, produce extreme nausea, excessive vomiting, and perhaps violent pain in the stomach.—See Clinical Lect., Lancet for 1830-1, p. 423. In pregnancy, it is very common for the stomach to become so disordered, that life is rendered miserable, and even endangered, by the constant vomiting, and inability to retain any food whatever in the stomach. Hence, in addition to venesection and leeches on the epigastrium, the hydrocyanic acid, strychnine, and conium, are the medicines in which Dr. Elliotson confides.—See Med. Gazette for 1832-3, p. 659.—Ed.

* We have derived much benefit in this distressing affection, by due attention to the diet, to the free state of the alimentary canal, and by the use of effervescing mixtures. Lying on the back in the open air has frequently given us immediate relief. For an excellent paper on this subject, see Dr. Miller's communication in the *Med. Repos.*, vol. iv., p. 34.—D.

quantities of brandy, the aromatic spirit of ammonia, or laudanum.

[Vomiting is frequently only a symptom of disease of the stomach itself. This is the case in chronic inflammation of the organ, in schirrhous of the pylorus, and in ulceration of the mucous coat. When the latter membrane is either ulcerated or merely weakened by any previous morbid change, the effort of vomiting sometimes occasions a laceration of the other coats of the stomach, and a fatal effusion of its contents in the abdomen is the immediate result.*]

SPECIES VII. LIMOSIS DYSPEPSIA. INDIGESTION.

THE APPETITE FASTIDIOUS; THE FOOD DIGESTED WITH DIFFICULTY; HABITUAL COSTIVENESS.†

THIS is by far the most complicated of all the disorders belonging to the present genus. The three preceding species may often be traced by themselves, or in a state of separate existence. Dyspepsy may be regarded as consisting in a combination of their respective symptoms irregularly intermixed; sometimes one set of symptoms taking the lead, and sometimes another; with a peculiar tendency to costive bowels, and especially that species of costiveness which we shall hereafter have occasion to denominate *coprostitis obstipata*, dependant on a weakly temperament or a sedentary habit, and in which the discharged feces, instead of being congestive and voluminous, are hard, slender, and often scybalous.

Dyspepsy, therefore, in the language of Dr. Cullen, may be described as “a want of appetite, a squeamishness, sometimes a vomiting, sudden

* See J. N. Weekes on rupture of the stomach, in Med. Chir. Trans., vol. xiv.—Lallemand, art. RUPTURE, in Dict. des Sciences Médicales. Examples are recorded, in which a fluid, containing urea, and having the sensible properties of urine, was vomited. In one interesting case, under Dr. Bright, in the Westminster hospital, the patient, a young woman, had been for three months unable to void her urine without the aid of the catheter. The particulars are mentioned in the Lancet for 1832–3, p. 704.—Ed.

† “Lenteur, difficulté, état pénible des digestions.”—(Dict. de Méd. et Chir. Pratiques, vol. vi., p. 387.) Such is M. Jolly's definition. Dyspepsy occurs in so many different affections, and under such a variety of circumstances, that many excellent physicians hesitate to set it down as a distinct and original disease itself. Besides, as digestion is a complex function, in which the action of parts variously organized is concerned, its disorders must be very different in different examples, according to the tissue affected, whether nerve, muscular fibres, or a part or surface designed for secretion. Dr. Abercrombie, in considering dyspepsy, chiefly directs our attention to cases in which the derangement is of a functional nature, or not connected with any change of structure, either of the stomach itself, or of any of the neighbouring parts. The muscular action of the stomach may be deficient, so that the alimentary matters remain in it too long, are imperfectly changed, and un-

and transient distentions of the stomach, eructations of various kinds, heartburn, pains in the region of the stomach, and a bound belly.” Yet none of these are uniformly present, and all of them seldom. So that, as already observed, the symptoms of cardialgy, flatus, and emesis, with a few others, enter in irregular modifications into dyspepsy, as those of dyspepsy enter into hypochondrias. [Among the most constant symptoms of dyspepsy are, a furred tongue, flatulence of the stomach, and fretfulness, or depression of spirits. They may arise primarily from disorder or disease in the stomach itself; or they may depend upon an affection of the brain, liver, bowels, or some other remote or adjacent part.—(See *Armstrong's Morb. Anat. of Stomach*, &c., p. 68.) The necessity of a careful discrimination of the original affection by the practitioner is quite manifest.]

There is also another complaint, which frequently enters into the multiform combination of maladies, of which dyspepsy is the general expression, and which has rarely been noticed by writers, although it is often a very troublesome symptom, and that is, gravel. In treating of gravel, or lithia, as an idiopathic affection, we shall have to notice, that one of its chief and most common causes is an excess of acidity in the *primæ viæ*; and, as such excess is almost constantly to be found in dyspepsy, gravel must frequently attend or follow, and is even a necessary effect where there exists what has been called a calculous diathesis. And, for a like reason, where there is a podagric diathesis, gout in some form or other is a frequent concomitant.

The grand proximate cause of the three preceding species is debility of the stomach, whence, among other evils, an impaired secretion of gastric fluid. In the present instance, the debility is not often confined to the stomach, but extends to the intestinal canal, and the collati-

dergo chymical decomposition. 2. There may be a deficiency of the corresponding and harmonious intestinal action, interfering with the second stage of digestion, and giving rise to imperfect chylicification, and various morbid actions in the upper intestines. 3. The various fluids may be deficient in quantity, or morbid in quality. 4. If the mucous coat of the stomach be morbidly irritable, the muscular coat will probably be too easily excited to action, and substances will not remain in that organ a sufficient time for healthy digestion; but after producing much uneasiness, will either be rejected by vomiting, or propelled in a half-digested state into the intestine, where they prove a new source of irritation. If the irritability occur in the intestine, the articles may undergo the proper change in the stomach, but be propelled too rapidly through the bowels for healthy chylicification.—See Abercrombie's *Pathol. and Practical Researches on Diseases of the Stomach*, &c., p. 73, ed. 2. These views will serve to correct and modify certain doctrines, delivered in the present section of the Study of Medicine. It may be observed, however, that the generality of writers insist on a weak, torpid state of the alimentary canal in dyspepsy, and doubts are sometimes entertained about the soundness of the theory which refers particular forms of this disorder to morbid irritability of the mucous coat of the stomach and bowels, independent of chronic inflammation.—Ed.

tious viscera, as the mesentery, the spleen, the pancreas, and especially the liver, in which it most frequently commences; and hence another cause of the great complexity of this disease.

The debility, and indeed torpitude of the intestinal canal, is evident from the habitual costiveness which so peculiarly characterizes this affection. Whether this be direct or indirect, intrinsic or sympathetic, as harmonizing with the weakness of the stomach, it is not easy to determine: but nothing can be a stronger proof of the great inactivity of the intestinal tube, from whatever cause produced, than the feebleness of its peristaltic motion, notwithstanding the acrimonious matters that are so frequently diffused over its inner surface.

The imbecility of the liver is equally obvious in most cases, from the small quantity of bile that seems to be secreted, or its altered and morbid hue, as evinced by the colour of the feces, which, in some instances, are of an unduly dark, and in others of an unduly light tint; and possibly from the inactivity of the intestines themselves, whose peristaltic motion is conceived by Dr. Saunders and other pathologists to be, in a great measure, kept up by the stimulus of the biliary secretion.

When the mesentery is affected, the chyme is generally obstructed in its passage to the thoracic duct, and the general frame, deprived of its needful nutrition, becomes flaccid and emaciated; and from a collapse of the minute vessels on the surface, assumes a wan or sallow complexion.

It is highly probable that the pancreas and spleen are both also affected in many cases of dyspepsy. Of the actual part taken by either, in the process of digestion, we have already had occasion to observe that we know but little: but we do know that the pancreas pours forth a considerable portion of the fluid which holds the solid part of our aliment in solution: while, in most of the cases of dyspepsy brought on by a habit of drinking spirituous liquors, the spleen is evidently affected as well as the liver.

It is in this state of the disease that we frequently meet with that tenderness or other uneasiness in the epigastric region, and that peculiar hardness of the pulse, often accompanied by febrile symptoms, which Dr. Wilson Philip has pointed out as pathognomonic of what he calls a second stage of the disease.—(*Treatise on Indigestion*, &c., p. 41, 8vo. London, 1824.)

It has also been well observed by Dr. Philip (*Op. cit.*, p. 323), that the lungs are, in many instances, apt to associate in the morbid action of the digestive organs, when it has become chronic, and to produce, as a result, a peculiar variety (with him *species*) of consumption, to which he has given the name of dyspeptic phthisis. The dyspeptic character of the disease, however, and especially the hepatic symptoms, together with those of lowness of spirits, flatulence, and other hypochondriacal affections, rarely fail to accompany it when complicated with phthisis, and point out its real source; and the cure must be chiefly directed to the primary malady, how much soever the induced symptoms may

also demand our attention; for it will be in vain to subdue the latter, while the former is still suffered to bear sway.

It must nevertheless be admitted, that in some instances the secondary disease seems to afford relief to the primary, and that the organ first affected recovers its health in proportion as that subsequently affected yields to the attack; in the same manner as, in erysipelas and the migratory forms of herpes, the eruption travels forward, the part relinquished heals, and fresh parts are affected in succession. In all such cases, the secondary complaint becomes a new malady, and must often be followed up under another principle and another mode of treatment. And, not unfrequently, we can very advantageously take a lesson from this peculiar march of nature; and, by exciting an artificial irritation in some neighbouring and less vital part, can draw off the morbid action into such quarter. It is by this means that blisters, setons, and other counter-irritants are so frequently found productive of the best advantage. And as a disease of the alimentary canal is thus sometimes communicated or transferred to the lungs, so a morbid state of the lungs is sometimes extended to the stomach, of which Dr. Gardiner has lately furnished us with a striking example.—(*Trans. of the Medico Chir. Soc. of Edinburgh*, vol. i., 8vo. 1824.)

In chronic inflammation of the stomach, and even in that form of it which terminates in ulceration of the organ, and a fatal effusion of its contents in the abdomen,* we also meet with several, and sometimes all the symptoms of dyspepsy; but as dyspepsy occurs here merely as a secondary or induced affection, it will be more regular to examine the nature and effects of this cause hereafter.

Under whatever form, and from whatever cause the disease occurs, there is a considerable degree of general languor and debility. Exercise or exertion of any kind soon fatigues; the pulse is weak; the sleep disturbed; the extremities are cold, or rendered so on slight occasions; and the tongue for the most part is furred, or covered with a creamy mucus, in the morning. Yet this last symptom is not always to be depended upon; for it is sometimes wanting in the disease, and sometimes common to those who have no such disease whatever, and are in the enjoyment of habitual health.

That dyspepsy should be connected with a morbid condition of any of the adjoining organs, is by no means difficult to conceive, when we reflect that they are all concerned, directly or indirectly, in completing the great object of the digestive process, which is that of furnishing a constant supply of nutrition for the system at large. Digestion is commonly supposed to take place in the stomach alone; but this is an erro-

* See Abercrombie on the Pathology of the Stomach, &c. in *Edinb. Med. and Surg. Journ.*, No. 78; also in his *Pathological and Practical Researches on Diseases of the Stomach*, &c., p. 17, ed. 2. *Edinb.* 1830; Elliotson's case of ruptured stomach, in *Med. Chir. Trans.*, vol. xiii., p. 31; also Louis in *Archives Gén. de Méd.*, tom. v.

neous view, though the stomach may be regarded as the chief link in the great associate chain. In the stomach, as we have already seen in the poem to the present class, the food is only broken down into the pulstaceous mass called chyme, and thus converted into the mixed principles of oil, gelatine, and sugar, and little else; for, though we have some traces of animalization, they are rudiments, and nothing more. Yet this, which is the first, is the most important stage of digestion; and its perfection depends upon the vital power. Where this is small or enfeebled, the process of chymification is necessarily impaired or interrupted: the wonderful machinery of the stomach, which finds no parallel, not only without the body, but in any other part of it, is disturbed or impeded in its operation; and its fluids are poured forth too sparingly or too inconditely.

The next stage of the digestive process takes place in the duodenum, which easily admits of distention, and receives the food in the form of chyme from the stomach. Here the bile, the most highly animalized of all the secretions, and abundance of the pancreatic juice, meet it, and a new play of affinities commences; the bile, as supposed by Fourcroy, being separated into two parts, its saline principles and its resin. The latter is discharged with, and gives a colouring matter to, the excrements; the former become decomposed, attenuate the chyme, communicate their azote, and thus complete its animalization; while the juice of the pancreas dilutes and holds the material in solution, and probably contributes to some other effect, but which has not yet been detected. In this liquid state, it is called chyle. The recrementory part, which descends into the larger intestines, is attacked, as it proceeds, by the mouths of a considerable number of lacteals, that drink up whatever small quantity of the chyle may be accidentally intermixed with it; while the great body of this fluid is absorbed in the duodenum itself, by an innumerable host of the same vessels which concentrate their mouths on its inner surface.

We thus see how largely the digestive processes ranges, and from what a wide spread of organs, closely sympathizing with each other, the disease of dyspepsy may proceed. But the finishing touch still remains to be added: the absorbed chyle, before it becomes completely assimilated, has to be exposed to the action of the atmosphere, and for this purpose has to travel to the lungs. What change it sustains in consequence of this exposure, will be the subject of a subsequent inquiry. At present it is sufficient to show the connexion which subsists between the stomach and the lungs in the common function of providing for the sustenance of the animal machine; and to indicate the means by which a morbid action of the former may be communicated to, or lay a foundation for impaired action in, the latter; since, to say nothing of the sympathy of, approximation, or of that sympathetic influence which is always found to take place between the extreme links of a chain that runs through any

part of the animal machine, it must be obvious that if the chyle, which originates in the stomach, and, when in a state of health, communicates a peculiar stimulus to the lungs, as it enters their substance in combination with the recurrent and exhausted blood, should be conveyed to them in an unhealthy condition, this peculiar stimulus may be changed in its mode or degree of action, and the lungs, in consequence, become a sufferer; more especially where they are predisposed to any kind of morbid action. And hence another origin of dyspeptic phthisis, which, like every other modification of the disease, may depend, therefore, upon imbecility of one or more of the digestive organs.

The common causes of this imbecility, whether confined to the stomach, or co-extensive with the associate viscera, may be contemplated under two heads, *local* and *general*; under both which they are still further resolvable into the two opposite extremes of deficient and excessive stimulation; and, consequently, into a divergence of any kind from that medium of excitement and activity, upon which health is made to depend.

The local remote causes are, a too large indulgence in sedative and diluting substances; as tea, coffee, and warm water, or similar liquids taken as a beverage; or an equal indulgence in stimulant and acrid materials, as ardent spirits, spices, acids, tobacco, whether smoked or chewed, snuffs, a daily habit of distending the stomach by hard eating or drinking; or a rigid abstemiousness, and very protracted periods of fasting.*

The general remote causes are, an indolent or sedentary life, in which no exercise is afforded to the muscular fibres or mental faculties. Or, on the other hand, habitual exhaustion from intense study, not properly alternated with cheerful conversation; becoming a prey to the violent passions, and especially those of the depressing kind, as fear, grief, deep anxiety; immoderate libidinous indulgence; and a life of too great muscular exertion. Perhaps the most common of this latter class of causes are, late hours and the use of spirituous liquors.

Dyspepsy is hence presented to us under several varieties, of which the two following are the chief:—

* The following facts are noticed by Professor Elliotson, in proof of the great length of time certain substances will remain in the alimentary canal, and be the cause of various complaints. In the Philadelphia Journ. for 1822, there is an account of a coagulum of milk, which was vomited two months after it had been taken. Dr. Elliotson has seen a coagulum of milk, like birdlime, which had remained a week in the stomach, producing the greatest uneasiness. Dr. Barlow has recorded an instance, in which sulphate of iron pills were discharged, per anum, a year after they had been taken. Dr. Elliotson has seen a piece of salmon vomited by an infant, a month after it had been swallowed. A boy swallowed thirty grapes without chewing them, and after three months' frequent vomiting and severe suffering, he was cured by an active purgative medicine; ten of the grapes came away whole even then.—Lect. at London University, in Med. Gazette for 1832-3, p. 660.—Ed.

- a** Organica. Originating in the digestive organs, and principally confined to them.
- β** Enervis. Originating in a relaxed state of the constitution from causes acting generally.
- Enervative indigestion.

For both these, the general principles that should govern us in attempting a cure are the same, though the means of carrying such principles into effect will admit of diversity.

Under what shape soever the disease may present itself, the first thing to be enjoined is a relinquishment of whatever cause has laid a foundation for it; we must next palliate the symptoms that aggravate and continue the disease; and, lastly, we must restore the debilitated organs to their proper tone; or, in other words, we must correct or remove what is called, though not very precisely, the proximate cause of the malady.

The patient must, in the first place, be convinced of the necessity of putting himself under a new rule of conduct, and be deeply impressed with the idea that, though he may have continued his late plan of life for a considerable period of time without having sensibly suffered for it, yet, now that he is suffering, nothing but his conforming to another plan will remove his present complaint.

Severe and long continued study,* protracted, as I have often known it, through ten hours a day for many months, without any relaxation or interchange of pursuit, must give way to the exercise of walking or riding, and this not occasionally, but daily; and to the still better cordial of cheerful conversation. The last is of very great importance; and without it even exercise itself will be of little avail: for the mind, accustomed to a certain track of intellectual labour, will otherwise relapse, even while riding or walking, into the same habitual course, be dead to the most fascinating prospects around it, and become exhausted by its own abstraction. And it is to characters of this kind, perhaps, more than to any other, that the amusements of a watering-place promise ample success; where the general bustle and hilarity, and the voluntary forgetfulness of care, the novelty of new scenes and new faces, and new family anecdotes, and the perpetual routine of engagements, that fill up the time with what would otherwise be trifles and frivolities, reverse the mischievous order and monotony of the past, break the sturdy chain of habit and association, and give leisure to the worn-out sensory to refresh itself.

Where the same effect has proceeded from a town life of fashionable follies and dissipation, nothing is more common than to recommend a like change of residence; but in this case,

though it may be a change of residence, it is not a change of life; and hence it is too often made without any benefit whatever. A total retreat from the world, the unbroken seclusion of a remote hamlet, the sober society of a few intimate friends, simple meals, and early hours, instead of close and heated rooms, crowded and motley routs, costly feasts, and midnight madrigals, are what are specially called for in this instance, but are not always to be met with in the resort of a watering-place. In such as are still distinguished for their quiet and unfrequented shores, where all is rude and simple, and spruce squares and long-drawn parades have not yet put to flight the scattered and irregular cottages of former times, these advantages may still be obtained. But it is rarely that patients, who are suffering from a life of dissipation, will consent to relinquish the higher attractions of our gayer and more public retreats, for what they are apt to esteem the dullness of an unfrequented coast, till it is of little importance whether they go anywhere, or remain at their own homes.

In like manner, the habitual use of hard eating and drinking must give way to a wholesome plainness of diet; though I am afraid that not a little mischief has often ensued from rigidly compelling the man, who is suffering from a long habit of the former, to abandon this habit at once, and run to an extreme of abstinence. Nothing can be more injurious. Even in full health, the animal frame, though it may be brought to any extreme by degrees, very ill brooks abrupt changes; and I have often seen, where such changes have been attempted in an enfeebled constitution, that they have introduced worse complaints than they have been intended to remove. The use of tobacco is not, in our own day, employed very often to such excess, whether in smoking or chewing, as to become a very alarming cause of dyspepsy: but I have known instances where the former has been suspected, though perhaps unjustly, of having been the cause of this complaint, and where an abrupt prohibition of its entire use has introduced a dangerous atrophy.

It is certain, however, that a free use of tobacco, under either or any form, has produced very severe dyspeptic affections; and, consequently, in such cases it ought to be relinquished by degrees. Nor is it difficult to conceive by what means tobacco thus acts; for, like opium, it is a stimulant readily producing a narcotic effect, or, in other words, rapidly exhausting the sensorial power. In chewing, a considerable portion of tobacco is conveyed to the stomach along with the saliva: in smoking, a somewhat smaller quantity is conveyed in the same manner; and in both, the salivary glands are excited to a great waste of secretion; which cannot take place without impairing the chymificative process indirectly, as the introduction of the tobacco into the stomach impairs it more immediately. The *areca*, or Malabar nut, though a good bitter, when chewed for a long time, is well known to impair it in the same manner. Even in the form of snuff, tobacco has not un-

* "Le cerveau est, sans contredit, l'organe dont les affections réagissent avec le plus d'énergie sur l'état des digestions.—Il suffit même que le cerveau, fortement préoccupé, n'apporte plus à l'acte de la digestion le concours de son influence, pour qu'il y ait dyspepsie."—Jolly in Dict. de Méd. et Chir. Pratiques, t. vi., p. 387.—Ed.

frequently been found to produce the same result; partly, perhaps, from the paresis of the olfactory nerves, in which the stomach participates by sympathy, and partly from the portion of tobacco that is constantly passing into it from the nostrils. "I have found," says Dr. Cullen (*Mat. Med.*, vol. ii., p. 275), "all the symptoms of dyspepsy produced by snuffing, and particularly pains of the stomach occurring every day. The dependance of these upon the use of snuff became very evident from hence, that, upon an accidental interruption of snuffing for some days, those pains did not occur; but upon a return to snuffing the pains also recurred; and this alternation of pains of the stomach and of snuffing having occurred again, the snuff was entirely laid aside, and the pains did not occur for many months afterward, nor, so far as I know, for the rest of life."

Dr. Cullen tells us in another place (p. 274), in proof of the same fact, but in proof, also, that the habit is sometimes variable in its influence, that he knew a lady who had been for more than twenty years accustomed to take snuff, and that at every time of day; but who came at length to observe that snuffing a good deal before dinner took away her appetite; and that even a single pinch taken at any time in the morning, destroyed almost entirely her relish for that meal. When however she abstained entirely from snuff before dinner, her appetite continued as usual; and after dinner, for the rest of the day, she took snuff pretty freely without any inconvenience.

Not in manner of life alone, but in manner of food, should we rigidly proscribe whatever we find to be a cause of indigestion. And hence dyspeptic patients should pay a particular attention to themselves, so as to discriminate between the viands that sit easy on the stomach, and those that render it uncomfortable; for nothing in a morbid state is more capricious than this organ, and twenty different cases may perhaps demand as many varieties of regimen. Thus tea of all kinds, and especially green tea, is generally accounted a narcotic. Dr. Smith and Dr. Lettsom endeavoured to trace up its narcotic principle by experiments, and it is to this principle that Dr. Cullen ascribes the deleterious effects it produces upon some stomachs. Yet while it acts as a narcotic upon many persons, upon others, and myself among the rest, it proves powerfully agryptic; and, if taken on going to bed, keeps up wakefulness through a great part of the night.*

* Among the causes of indigestion deserve to be enumerated, imperfect mastication from loss of the teeth, or from the habit of swallowing the food too rapidly; sympathy of the stomach with the uterus, brain, kidney, or other organs, and violent emotions of the mind. Then, as Professor Elliotson justly observes, with reference to dyspepsy dependant on the stomach and intestines, there may be either a real debility of them, an inflammatory state, or an organic disease of them: excesses at table debilitate and destroy the tone of the stomach. Chronic inflammation of this organ is likely to be brought on by constant irritation of it. When organic disease occurs, the cardia, or pylorus, is

We must first then prohibit, in our endeavours to effect a cure, whatever we know to be a local or general cause of the disease. Our next intention should be, to palliate the symptoms that aggravate and continue it.

As the stomach is often overloaded with crudities and acidity, Dr. Cullen recommends an emetic at the outset. I have rarely found this of use: it often adds to the debility of the stomach; and at most is only of service for a few hours. For so long as the cause continues by which an accumulation of undue materials is produced, this effect will be perpetually taking place, and an emetic might be necessary every day.* The most rational mode of prevention is, to limit the stomach to such food as it will most easily digest; to allow it in small quantities; to quicken its removal by gentle aperients that may increase the peristaltic action, and warm tonics that may invigorate the digestive organs. A spare diet, however, though often recommended, is rarely found of service, and very generally adds to the disease: for as the stomach and bowels have been accustomed to the stimulus of food, and a certain degree of impletion, if this be not maintained the atony will be increased, the natural function still further impaired, and all the symptoms of uneasiness be aggravated. A moderate proportion of excitement and impletion is hence imperiously called for; and our discretion is principally to be exerted in determining the nature of the viands and the degree of impletion which will best agree with the stomach, and which it may most easily master.

For the correction of flatulence, most of the carminatives noticed under the fifth species of this genus may be conveniently employed; and for that of acidity, limewater, the acidulous alkaline waters, the carbonates of soda and potash, and the absorbent earths. Magnesia is a remedy of peculiar value for this last intention. In some cases of great obstinacy, but evidently dependant upon a chronic tendency to an acetous fermentation, magnesia, given in the proportion of an ounce a day, has effected an entire cure;† and in all cases it resists the costiveness as well as the acidity, and is far less disposed to coacervate in the alimentary canal, than the calcareous earths. It is also, as I have already observed, a powerful antidote against that class of calculous concretions in the kid-

generally the seat of it; but there may be ulceration, or a thickening, or a softening, of the texture of any portion of the stomach.—See *Med. Gazette* for 1832-3, p. 658.—Ed.

* On this point, Dr. Elliotson's advice is judicious:—"Suppose that any thing injurious in its quality, or in its quantity, is the cause, the shortest way is to give an emetic, and empty the stomach, and it is *much best to give one that does not produce nausea, but an evacuation*. The sulphate of zinc is as safe as any you can exhibit." In fat, short-necked subjects, he recommends bleeding to be practised before an emetic is given, which is to be followed by the exhibition of calomel, senna, and salts.—Ed.

† See Dr. Watson's communication, *Medic. Observ.*, vol. iii.

neys and bladder that depend upon an acid principle.

The eructations that occur in dyspepsy, however, are not always acid. They are often of a compound and very offensive taste, and give to the breath the smell of carburetted hydrogen gas, or rotten eggs: as though the gastric juice were incapable of performing its proper office, and the food were retarded in the stomach till the process of putrefaction had commenced. In this case, instead of avoiding acids, we should recommend a free use of them, from whatever quarter they may be obtained; as they not only tend to correct the fetor, but to strengthen the stomach. The mineral are the most powerful; and of these the sulphuric is by far the pleasantest. It may advantageously be employed as a medicine; but for acidulated dietdrinks it must yield to the vegetable acids. These are of three kinds, native, distilled, and such as are obtained by fermentation. The first are commonly the most grateful, and especially when they exist in the form of fruits; but they are apt in weak stomachs to set free a large quantity of air, and consequently to produce a very troublesome flatulence, and even promote the acescent disposition of the organ. The citric and the oxalic may be exceptions; and there may be also a few others, but they are not numerous; and where these cannot be procured, we must have recourse to the acids elaborated by distillation, or a fermenting process. The last are called vinegars, whether obtained from malt, weak wines, or sugar; and being of themselves, when properly refined, very pure and dilute, they are capable, with a little care, of being rendered highly grateful.

Costiveness is a symptom of dyspepsy still more common than acidity, and one that requires a very vigilant attention. In our attempts to remove it, we should always bear in mind that it is a chronic and not a temporary concomitant; and, consequently, that violent purgatives are of all things to be avoided; and that such aperients should be preferred which act gently, and rather by soliciting the peristaltic motion of the bowels to the regularity of health, than by irritating them to a laborious excitement.

Rhubarb is, for this purpose, one of the best articles in the *Materia Medica*; for, while by its aperient power it relieves the present distress, we cannot have a much better tonic than its bitter. Where the bowels are merely sluggish, it will prove sufficient without any other cathartic; though it is better to combine it with soap and such aromatics as agree with the stoap. It is often however incompetent of it-

self; and in such cases derives, in the form of an extract, a valuable assistance from half the quantity of the extract of aloes, or the compound extract of colocynth.*

Since the publication of M. Daubenton's little tract in an English dress, very small doses of ipecacuanha, not exceeding a grain or a grain and a half, have been extensively tried, upon the recommendation of this celebrated physiologist. The intention appears to be that of exciting a change of action in the secretions of the stomach; but notwithstanding the advantage which is said to have been derived from this medicine by the writer himself, it does not seem to have succeeded in this country; and, indeed, the dose is so small, that little effect of any kind seems capable of being produced by its use. By some writers it is supposed that, in such minute proportions, it will slip over the pylorus, and prove aperient by acting on the intestines. I have rarely, however, found it to do this alone, though it is a useful auxiliary with aperients of a more decided character. And where there has been great irritability of the stomach, I have known it even in the dose of a single grain excite so much nausea as to prohibit its further use. Far more service has occasionally been produced by an external application of the tartar-emetic ointment, made in the proportion of four scruples of the tartarized antimony to an ounce of spermaceti cerate; the quantity of a hazelnut being rubbed in every night till the eruption consequent upon this application appears. In numerous diseases of the digestive organs, and particularly those of the stomach and liver, this kind of counter-irritation has been found highly useful, probably from the influence which is often produced through the whole length of a nervous fibre and its connecting branches or intersections, in consequence of exciting its extremity. It is to Dr. Jenner we are chiefly indebted for the attention which has lately been bestowed upon the nature and effects of this singular remedy, though it was occasionally in use long before his time.

The quicksilver, or blue pill, will also generally answer a good purpose; but it is chiefly to be employed where we have reason to apprehend that the one or both the portals of the stomach, and especially the pylorus, is in a scirrhus state; or that the dyspepsy is connected with a morbid condition of the liver, or some other allied viscus. In this case, much benefit has also been derived from the white oxide of bismuth, now more generally known as a cosmetic, under the name of *pearl-white*. For scirrhus affections of the stomach it has been tried successfully by Carminati, of Pavia;

* One thing particularly advised by Dr. Abercrombie is, to regulate the bowels by the daily use of very small doses of laxatives, combined with tonics, so as, without even purging, to imitate at all times that moderate but regular action, which attends the most healthy state of the bowels. For this purpose, various combinations answer; such as columbo powder, with carbonate of potass, and a few grains of rhubarb, taken once or twice a day; sulphate of iron with aloes; sulphate of quinine with aloes or rhubarb, and a few grains of ginger;

oxyde of bismuth with rhubarb or aloes.—See Abercrombie, op. cit., p. 79. Dr. Elliotson considers one of the best remedies for this state to be a very minute quantity of croton oil—about 1-12th, 1-6th, 1-4th, or 1-3d of a drop, given regularly with rhubarb and colocynth; and, if it should gripe, a small quantity of aromatic oil should be added. The patient may take a pill of this kind every night, and one copious stool will be produced by it in the morning.—(See Elliotson's Lect. in Med. Gaz. for 1832-3, p. 660.)—Ed.

and apparently with equal advantage in France. (*Beaumé, Journ. de Méd.*, tom. lxxiv.; *Heusland, Neue Annalen*, band i.) Independently of its discutient power, it has the virtue of allaying irritation in general; and on this last account, Dr. Odier, of Paris, has employed it satisfactorily in most of the acute diseases of the alimentary canal, especially in pains of the stomach, diarrhœa, and colic, as he has also in hysteria, and even in toothache.—(*Journ. de Méd.*, tom. lxxviii.) The best form of giving it is that of pills, in doses of from four to ten or twelve grains, four or five times a day.

In the meanwhile, we must never forget that our primary object is to restore the stomach, or the system at large where the stomach is only secondarily affected, to its proper tone and strength.

The general plan, as I have already hinted, must be the same; for, as the virtues of medicines can only be communicated to the system at large through the medium of the stomach; and as the state of the latter has at all times a powerful influence upon the former; there can be little doubt that, by improving the digestive function, the vigour of the system will be improved generally at the same time, and consequently that the energy of the whole of the moving fibres will be increased: while the collateral means of cure that are applied externally, as those of air, exercise, and sea-bathing, and which are chiefly designed to operate on the system at large, will convey an equal advantage to the stomach.

The principal evils we have to encounter in dyspepsy are, deficient action, and a relaxed state of the fibres. For these, there are three classes of remedies to which we may have recourse; stimulants, to increase the action; and bitters and astringents, to augment the tone. The first, however, are of a very doubtful advantage: for a lax state of fibres will bear very little increase of action without incurring an equal increase of debility; and hence stimulants can never be recommended alone, except in cases of emergency, as to remove a severe fit of pain or other inconvenience, and then only for a short period of time; but they may be combined very advantageously with either astringents or bitters, and particularly with those medicines that possess these qualities jointly.

Bitters, besides restoring tone where it is wanted, have another and more immediate advantage in the disease before us: for they directly attack that tendency to fermentation in the stomach which is one of the most prominent features of dyspepsy, and which is, indeed, the chief cause of the flatulence and acidity that so generally accompany it. Of this we have no doubt; for the experience of every day brings its testimony; and we employ bitters, as hops and quassia, for this very purpose, in our fermentable beverages.

Stimulants, astringents, and bitters, are then the three classes of medicine with which we are to make inroad against the intrenchment of dyspepsy. They may often be conveniently united, and have their forces hereby increased

in a more than double proportion. The stimulants, indeed, ought rarely to be employed by themselves, except in spasmodic pains, or some other temporary extremity. Many of these may be found in the list of carminatives already described under the species CARDIALGIA.

I have observed that dyspepsy is often grafted upon an hysterical or hypochondriacal diathesis; and in these cases, we may indulge in stimulants of a much warmer character, as camphire itself, asafoetida, the alliacea, the spicy aromatics, and even capsicum. Of the last it may be remarked, that, though the hottest of all the peppers, it has a less tendency to produce complaints of the head than any of the rest. It is one of the best carminatives possible in the case of flatulence from vegetable food, and admirably calculated to remove that stony coldness, which distresses a weakened stomach when attacked by a transfer of gout.

In selecting from among the simple bitters, we need not be particularly nice, for their principle is the same; the quassia perhaps possesses it in the highest degree, though some have doubted of this; then the gentians; and next to these columbo. Of the gentians the most powerful seems to be the *g. purpurea*, first imported into this country by Dr. Home, from Norway, and then known by the name of cursuta, from its Norwegian name skarrote. As a simple bitter it is best to unite it with some aromatic. The tincture of gentian of the London College, which is an improvement upon Stoughton's or the stomachic elixir, by exchanging the cochineal for the smaller cardamom seeds, is an excellent form for occasional use; but as alcohol should be habitually abstained from in the disease before us, it cannot be employed alone in such quantity as to promise any real benefit, though it may be allowed to enter as an ingredient into more compound remedies.

The bitter of the columbo is combined with a slight and not disagreeable pungency, and has an aromatic smell. It is hence peculiarly calculated for dyspeptic affections, and in most cases will sit easy on the stomach in the form of powder, in doses of fifteen or twenty grains; and will often give a check to sickness where bile is not present, more than any other medicine we can employ. It is singular, that, to the present hour, we are unacquainted with the plant that furnishes this excellent drug. Commerson believed it to be a species of *menispermum*; and Willdenow a species of *brionia*. [Formerly, the root was erroneously supposed to be named from the capital of Ceylon, which was regarded as the place from which it was exported. But according to Dr. A. T. Thomson, it is now known to be a staple article of export with the Portuguese at Mozambique, whence an entire root was taken to Madras by M. Fortin, in 1805, and a plant raised from it there by Dr. Anderson. From a drawing in the possession of the Linnæan Society, the plant appears to be of the natural order of *Menispermæa*; but the genus cannot be determined, in consequence of the female flowers not having been as yet seen.—(*London Dispensatory*, 2d

ed., p. 78.]] It seems to have been first noticed by Redi in 1685.—(*Experimenta*, &c., p. 142.)

As a plant uniting the two principles of an essential oil, warm without being unduly stimulant, and a powerful bitter, the chamomile is, for the purpose before us, one of the best remedies. It may be taken in a watery infusion, or an extract; but if in the former, the menstruum should be closely covered, that as little as possible of its volatile aroma may fly off; and the infusion should not be continued for longer than an hour; and perhaps a shorter period may suffice.

As we have medicines that unite the two qualities of bitterness, and a stimulant or aromatic warmth, so we have those also that unite the two qualities of a bitter and an astringent; of which the cinchona furnishes us with a striking example: and hence this medicine has been long, and deservedly, one of the most popular of any for debilities of all kinds, whether of the digestive organs alone or of the system generally. The cascarilla bark has pretensions of a like kind, but far inferior in degree, notwithstanding the high encomiums that have been paid to it by the Stahlian school, which endeavoured to hold it up as a rival to the cinchona. There are many stomachs, however, which will not bear the latter, even in decoction or infusion; and in such cases, either the sulphate of quinine, or, in lieu of this, the cascarilla, may be prescribed.

The acids, both mineral and vegetable, are valuable astringents in particular states of the stomach resulting from dyspepsy; but, it is obvious, that, from the tendency of this organ to co-operate in so many cases in the production of a superabundant acetous fermentation, acids cannot at all times be had recourse to. I have occasionally, indeed, employed the mineral acids, and particularly a mixture of the nitric and muriatic acids, in the proportion of one part of the former to two of the latter, for the purpose of checking this tendency to acidity, in several instances with success; but the plan has not answered generally; and it will hence be better to limit this class of medicines to the intention I have already pointed out, or to delay them till we have by other means overcome the disposition of the stomach to this morbid action.

The other mineral astringents which have been employed besides acids are not numerous, and may be limited to the preparations of iron and zinc. As general tonics, these, under different forms, have proved very extensively successful; but they are less adapted to dyspepsy proceeding from primary imbecility of the stomach or its adjuvant organs; or, I should rather perhaps say, that they are apt to disagree with these organs till they have been restored to some increased degree of tone, beyond what they usually possess when medical aid is sought for.

I have observed, that there is always some degree of acid existing in the stomach in a healthy state; and we have seen, that one of the most troublesome symptoms of dyspepsy is a morbid increase of this principle. And hence, upon an idea that the acid, if thus formed in the

stomach, may of itself be sufficient to answer the purpose of the sulphuric, and reduce the particles of the metal to a due degree of tenacity, both the zinc and the iron are also frequently employed in the simple form of filings, rust, oxides, or calces; and often with the happiest success. And that an acid adequate to this end does in most cases exist in the stomach is sufficiently proved where the rust of iron is employed, by the black colour of the stools, which may be regarded as a test of the proper solution of the iron; as it may be also of the existence of bile in a state of healthy bitterness: for it is by a combination of the iron with the bitter principle of the bile that this blackness, which is a natural ink, and obtained by the same means as artificial ink, is produced. Some animals have a power of forming this sort of natural ink at option, as the sepia or cuttlefish, but whether by a solution of iron, I cannot undertake to say. This, however, is very probable, if it be used, as it is generally understood to be by the Chinese, as an ingredient in the manufacture of Indian-ink. The cuttlefish, when exposed to danger from the attack of an enemy, throws it forth very freely, employing it, indeed, as a means of defence; and effecting his escape by thus converting the water around him into a black muddiness, that sufficiently conceals him from view.

It is on this principle that the flowers or oxide of zinc have, by many physicians of great reputation, been preferred to the sulphate; and it is certain, that, in the form of an oxide, we can introduce a much larger quantity either of zinc or iron, than in that of a salt: but it does not follow from this fact, that the metal may be more efficacious; for, from the doubtful measure and strength of the acid existing in a free state in the stomach, there may not be enough to dissolve or form a salt with the whole of the dose, and consequently a considerable portion of it may be lost, or remain inert. And, on this account, I think it better to have recourse at once to the sulphate of both these metals, whenever it is judged expedient to employ them, than to trust to the chymical changes that may take place with so much precariousness in the stomach.

In employing the metallic salts, and, indeed, tonics of every kind, in disabilities of the stomach, it is a good rule to begin with small quantities, and advance to a full dose by degrees; thus reversing the method that it may often be found advantageous to follow in acute diseases, when the life of a patient may depend upon a bold practice, adopted instantaneously, and gradually remitted, as soon as the object has been obtained. The chronic character of dyspepsy, on the contrary, allows us time; and as no two stomachs will perhaps bear the same precise dose of a remedy with the same precise effect, on account of the caprice of this organ in a deranged state, it is better to feel our way before us, and to reach the proper point by degrees; for if we over-dose the patient at first, we add to the disease instead of opposing it, and require many days, perhaps weeks, to bring him

back to the actual state in which we found him.

In conjunction with this internal treatment, it is probable, also, that an external application of the voltaic power to the stomach may increase its energy. In the hands of Dr. Wilson Philip, it appears to have been of decided advantage.

[According to the reports of Dr. A. T. Thomson, Dr. Granville (*On the Hydrocyanic Acid in Pulmonary Consumption*, &c., 2d edit., 8vo. 1820; also, *Farther Observations*, &c., 1819), and Dr. Elliotson,* the prussic or hydrocyanic acid is a valuable medicine in dyspepsy, connected with morbid irritability of the stomach. Eighty years ago, it seems that nurses were in the habit of relieving the flatulence of infants by putting into the pap a laurel-leaf (*Langrish, Phys. Exp. on Brutes*), the virtue of which is supposed to have depended upon its containing a minute quantity of the acid under consideration. This remedy, however, was distinctly praised by Sprengel (*Pharm.*), in 1814, for its good effects in complaints of the stomach, dyspepsy, and hypochondriasis; and even at earlier periods, for these and other cases by Hufeland, Haller, Swediaur, and others. The dose for commencement may be one minim of the diluted acid, thrice a day, gradually increased to three. Strychnine, hyoscyamus, and conium, are other medicines calculated to lessen morbid irritability of the stomach: in the case which attends pregnancy, venesection, leeches to the epigastrium, and either some of these medicines or the prussic acid, may be tried.—(*Med. Gazette for 1832-3*, p. 659.) One of the most distressing symptoms, sometimes attending dyspepsy, is uneasiness in the chest, with occasional fits of palpitation; while, in primary organic diseases of the heart, many of the most troublesome symptoms of dyspepsy also occur, particularly flatulence. In such cases, Dr. Macleod (*Med. Phys. Journ.*) recommends the exhibition of hydrocyanic or prussic acid, as a means by which the patient's sufferings may be considerably lessened. In one instance of diseased heart, accompanied by dyspeptic complaints, ten drops of diluted prussic acid were prescribed in a five-ounce mixture, of which two table-spoonfuls were taken at first three times a day, and afterward the whole quantity in the course of twenty-four hours. From Dr. Macleod's account, the medicine rendered the patient's journey to the grave much more bearable than it would otherwise have been.]

While, however, a proper course of medicine is pursued, a proper course of diet and regimen must accompany it, or, with the utmost professional skill, we shall make no progress. And hence, to the remarks already made at the outset, that, where the disease has been brought on by a life of indolence, sedentary occupation, or too free indulgence of any kind, the general habit must be changed, and regularity of meals,

sleep, and exercise be rigidly insisted upon, it is necessary to add a few other observations to the same purport.

One substantial meal of solid animal food daily is sufficient for a man in full health, engaged in a life of ordinary labour. Yet there are many who, without any labour, are from a long habit obliged to take two or even three. But the habit is bad, and cannot too soon be broken through. It follows, therefore, of necessity, that where the stomach is weak, the toil of digesting one full meal of animal food is the most that should be put upon it. This should take place as nearly as may be to the hour of noon, certainly not later than one or two o'clock, so as to occupy the middle of the wakeful period. The animal food should consist of one dish only; and be confined to such as is lightest of digestion, or as the peculiar state of the stomach may call for; for, in both these respects, there is a considerable difference. Thus shell-fish do not always agree with weak stomachs, and will sometimes excite great uneasiness, with pyretic heat, and even throw out a nettle-rash, or some other cutaneous eruption. Yet where they sit easy and are relished, several of them, as the crab and lobster, are found to neutralize acidity in the stomach more readily and effectually than any other kind of animal food: an effect we should little predict, considering that they give out, on a chemical analysis, a smaller proportion of ammonia than the flesh of quadrupeds, birds, or even amphibials. The food of young animals is less nutritive than that of old, but it is, in general, digested with less irritation. Many writers have arranged the different animals that furnish food in tables, founded upon their supposed degree of nutriment. But they have drawn them up with considerable variations; in some instances apparently according to their own fancy. I have not space to enter into a comparison of these, nor is it necessary. Those who have leisure for such a study may turn to Dr. Darwin's, which is perhaps one of the best, and which they will find in his *Zoonomia*. Generally speaking, the tenderest food is that of the gallinaceous birds; then that of the ungulated quadrupeds; among which the stag, or cervus kind, claims the pre-eminence; and to this succeed the ox, sheep, and hare, in the order in which they are here placed. Yet it should be observed, that the last, though less nutritive than the preceding, is more easily digested than several of them; as it should also, that the flesh of animals in their wild or native state, though less coveted by a pampered palate, offers a more wholesome and digestible aliment, and is more perfectly animalized, than that of animals cooped up and fattened for the table. Below the hare, we may place the webfooted birds that are ordinarily brought to market; and below these, the oyster and lobster tribes, and lastly the numerous genera of fishes. The simpler the cookery of all these the better; for the complicated processes employed to give new forms to the productions of nature, or even to break them down for the use of the stomach, and thus keep the masticatory organs in a state

* Numerous Cases, illustrative of the Efficacy of the Hydrocyanic or Prussic Acid in Affections of the Stomach, &c., 8vo. 1820.

of indolence, injure, instead of promoting, the health of a dyspeptic patient. We have already observed, that the saliva forms an important part in the chymistry of digestion, and it is best applied to the food when first secreted and in the act of mastication; and hence, if this act be prevented or suppressed, the food is without one of its auxiliaries. It is on this account that concentrated jellies, and all mashed dishes, sit more uneasily on a weak stomach than meat taken in a solid form.*

The vegetable nutriment should be such as is least disposed to ferment in the stomach; and hence all kinds of new bread, sweet preserves, confectionary, and pastry, must be sedulously avoided; and the crust of bread, toasted bread, and unleavened biscuits take their place. The farinacea, whether seeds or roots, as rice, wheat, flour, in the form of light and simple pudding, and potatoes, may be allowed in moderation. Water too is the best beverage; but where there is great flatulence, a small portion of brandy may occasionally be added. The only condiments that can be conceded are salt and spices; pickles might be admitted where acids constitute a part of the medical treatment; but they are disposed to provoke a false appetite, and hence to weaken the stomach by overloading it †

From fixing the principal meal so near the hour of noon, it is clear that we suppose the day to commence at a very different period from the ordinary regulations of fashionable life; in which the bed is rarely quitted before nine or perhaps ten o'clock, after a night of imperfect and feverish sleep, when the languid idler immediately proceeds to a breakfast of tongue, ham, and eggs, in addition to the ordinary materials of his meal, as though he had been already labouring in the field for two hours; and, by means of their combined stimulus, fills his stomach with a load which might indeed do good to the husbandman, but to himself proves nothing more than a mischievous oppression. Yet to this morning toil of the stomach succeeds,

* Dr. Beaumont (*Exp. and Obs. on the Gastric Juice*, p. 269) has published a table showing the length of time required to digest certain articles of food. He found that boiled rice, pigs' feet, and tripe, soured and boiled, were chymified in an hour; raw eggs, when whipped, boiled, and fried, salmon-trout, and barley soup, in one hour and thirty minutes; roasted turkey, goose, and pig, in two hours; oysters, when raw, in two hours and fifty-five minutes; when roasted, in three hours fifteen minutes; beef-steak, roast beef, broiled and boiled mutton, in three hours; fresh bread, and boiled potatoes, in three hours thirty minutes; potatoes when roasted or baked, in two hours thirty minutes; chickens, ducks roasted or boiled, beef soup, in four hours; and roasted pork in five hours fifteen minutes.—D.

† On the subject of Dietetics, the reader may consult Arbuthnot on the Nature of Aliments, 8vo. Lond. 1731; Fordyce on Digestion, 8vo. Lond. 1791; J. Abernethy on Local Diseases, including Derangements of the Digestive Organs; A. P. W. Philip on Indigestion, 8vo. Lond. 1826; J. A. Paris on Diet, Lond. 1827; J. Johnson on Morbid Sensibility of the Stomach, Lond. 1827.—En.

at about two o'clock, the ordinary luncheon in a still more solid shape; followed in the evening by a dinner of numerous courses, with high-seasoned condiments and a stimulating change of wines; the real business of this vain and frivolous life perhaps not commencing till the better disciplined peasant has begun his quiet sleep; when, roused by a flow of factitious spirits, and primed for gayety and gallantry, the votary of pleasure, as it is called, sallies forth to join his comrades at the allotted place of rendezvous, and to pass the midnight in hot and crowded ball-rooms, or in orgies of a still more exhausting nature. Of the whole of this career, the only rational part of it is the luncheon a little after mid-day: this may be copied by the invalid before us, as his dinner, but from all the rest we must carefully shut him out. He should quit his bed by six or seven o'clock in the morning in the summer, and by seven or eight in the winter; and, after having risen for an hour, he may partake of a light breakfast of milk, cocoa, saffrafs, or any other aromatic or warm-flavoured tea, with toasted bread, the crust of bread, or sea-biscuits, as observed already. The morning may be devoted to such exercises or recreations as may be most agreeable without producing fatigue. To this will succeed the chief meal of the day, upon the plan already laid down; and a light refreshment of the same nature as the breakfast should conclude the daily diet, a few hours before retiring to rest, which should never be later than eleven o'clock. Sea-bathing, or the shower-bath, before breakfast, will considerably add to the means of improvement wherever these advantages can be enjoyed, and particularly when the warmth of the season may give them the character of luxuries.

[The systems of dietetics offered to the world are innumerable, and marvellously contradictory to each other. Some, looking with an evil eye on the refinements of society, would bring us back to the simplicity of savages, and have us live "according to nature." Though when we ask, with the Prince Rasselas, what it is to live according to nature, we are sure to meet with no more satisfactory answer than what was vouchsafed to that noble inquirer. The truth is, however, that our bodies would be as little bettered as our minds, by going back to the state of savages; for it is now ascertained that savages are universally short-lived, and subject to sudden and violent diseases. Population increases slowly among them, and the healthiest and strongest of them, if compared with the average of well-fed civilized Europeans, will be found inferior both in strength and health. Some theorists, again, would have us live solely on animal food, and assert, that the human viscera bear vegetables "only in a grumbling way;" while others would reduce us to the diet of Nebuchadnezzar, and not leave a fleshpot in our kitchens. The different notions on dietetics by no means end here. Some sage doctors will never allow us to fill our stomachs, and some hold that they should never be altogether empty; some reduce the whole mystery of nu-

trition to a skilful exhibition of successive stimulants, and others to the exclusion of all that can interfere with the balsamic simplicity of the insipid chyle; some hold all fermented substances pernicious, and others think fermentation the best preparative for digestion. But, as the judicious critic, to whom we are indebted for the above reflections, has observed, how is it possible to say what is absolutely the best diet for human beings, when we consider under what an infinite variety of different habits such beings are found to live in health and vigour, and by how many opposite causes their health and vigour are impaired! The same diet that is sanative to one, whose digestion has been weakened by scanty and penurious living, cannot possibly be suitable to another who has suffered from a long course of repletion and excess. The regimen that is most wholesome for youth is not likely to be well fitted for old age; nor can that which answers for the active and laborious, be proper for the studious and sedentary. Nay, your dry and adust subject plainly requires a different regimen from that of the plump and succulent. A lover should not be dictated as a miser; nor a champion of the fancy like a prime singer at the opera. Every man differs from every other in some of the important attributes of age, habit of body, occupation, temperament, and disposition, to which may be added climate; so that all rules of diet must plainly require innumerable modifications to accommodate them to the condition of those classes of persons, even if it were possible to reduce them to certain classes. Besides all this, there are special and apparently capricious varieties of digestive power, which the learned called idiosyncrasy, by which the application even of those vague and variable rules must be constantly frustrated.—(*Edinb. Review*, No. 93, p. 38.) All directions which are rational, must be founded on the circumstances of the individual to whom they are offered; and even then cannot be deemed valid, until they have been confirmed by his particular experience. However, the general instructions given by the author of this work with reference to the diet of dyspeptic persons, may be considered as good and valuable.]

Proper temperature and clothing are also subjects of some importance; but, as we shall have occasion to enlarge upon these, more particularly when treating of *ERTHRIS*, I shall only observe at present, that the feet and chest should be kept especially warm, and that all extremes of heat and cold should be sedulously avoided; a general glow on the surface, when produced by exercise, will be advantageous, but it should not be carried to the extent of much sensible perspiration, as this might terminate in a debilitating chill. And where the languor is so extreme as to prevent exercise abroad, that of a swing or rocking-horse may be had recourse to at home; or where these cannot be endured, that of general friction, in any of the multiplied forms now in use, and especially friction of the stomach and belly, may be often employed as an advantageous substitute. Every tender mother is well acquainted with the benefit of such an

external stimulant to her infant; and when judiciously applied, it may often be rendered so to an adult in cases of great dyspeptic languor and weakness.

[In the valuable paper by Dr. Abercrombie on chronic inflammation and ulceration of the stomach are many judicious observations on dyspepsy. From the facts there related, it appears that the above dangerous affections of the stomach may exist with much diversity of symptoms. These may be severe, and indicative of serious disease, or they may be such as, without very great attention, are likely to be considered as merely dyspeptic. In one case of extensive malignant ulceration of the mucous coat of the stomach, which was under the care of Dr. Chambers, no nausea and sickness existed, and all the symptoms, such as tormina, tenesmus, and frequent discharge of small liquid bloody motions, seemed to indicate disease of the bowels; yet the latter parts were found after death very little affected.—(*Med. Gazette*, vol. i., p. 63.) There may be hardness in the region of the stomach, or nothing may be discoverable by the most attentive examination; and it is in fact extremely difficult to propose any rules by which chronic inflammation of this organ can be distinguished in its earlier stages. It may be suspected, when there is either permanent uneasiness in the region of the stomach, or pain recurring with regularity after meals, and incapable of prevention by attention to diet; when there is tenderness on pressure, especially if the pain and tenderness be always referred to a particular spot of small extent, and distinctly defined; when, along with the symptoms, vomiting occurs at short periods after meals, and after food of the mildest quality; and when, without any urgent or defined symptoms, a patient, with affections of the stomach, becomes progressively weakened and emaciated, in a manner which his symptoms, if considered as merely dyspeptic, could not account for. As Dr. Abercrombie confesses, however, none of these symptoms can be depended upon; most or all of them may exist in connexion with a state of the stomach which is merely dyspeptic; and, under a more serious form, they may end fatally, with every appearance of extensive disease, and yet no morbid change be discovered in the stomach or neighbouring parts. Yet he rightly urges the remembrance of the important practical truth, that symptoms, which at first sight appear to be merely dyspeptic, often depend upon chronic inflammation of the stomach. When there are grounds for this suspicion, he thinks that, though general bleeding is seldom admissible, much benefit may result from topical bleeding, blisters, issues, antimonial ointment, food of the mildest kind and in very small quantity, and the avoidance of stimuli and bodily exertion.—(See *Edinb. Med. and Surg. Journal*, No. 78, p. 12; also, *Path. and Pract. Res. on Diseases of the Stomach*, ed. 2, p. 17.)

The foregoing observations derive much confirmation from the statements of Mr. Annesley.—(*Researches into the Causes, &c. of the Prevalent Diseases of India*, vol. i., 1828, 4to.) In

warm climates, he says inflammation of the mucous membrane of the stomach is a very common form of disease; and it takes place to a greater or less extent in the advanced stages of dyspepsy, the dyspeptic symptoms being truly the effect of gastric inflammation.

Some highly interesting observations on this subject were published by Dr. Armstrong (*Morbid Anatomy of the Bowels, Liver, and Stomach*, p. 42, &c., Lond. 1828); and, if they be correct, a part of the difference in the symptoms, in different cases, may in some degree be explained by the chronic inflammation being sometimes situated in the serous, sometimes in the mucous membrane of the stomach; a topic which will be further noticed in treating of gastritis. There is something forcibly striking in the expression of the countenance and colour of the skin in most organic diseases. Thus, in tubercular disease of the lungs and elsewhere, the cornea becomes more shining, and the conjunctiva more pearly and blanched than natural, with a softness and almost pensiveness of expression; while the face grows more and more sharp, and the skin acquires a much more delicate hue. In scirrhus, the expression is that of more or less solicitude, and the skin commonly has a sallow tint, like that of the pale yellowish willow; whereas in fungus the skin has neither the delicacy attendant on tubercle, nor the sallowness accompanying scirrhus; but it is often of a dull muddled white, almost resembling that of tallow, or putty. Some change about the face and skin will frequently lead the experienced eye at once to suspect deep visceral derangement. Without being led away by first impressions, however, the pathologist will be careful not to confound the ventricular disturbance and sallowish aspect of the sedentary and studious dyspeptic with any organic disease of the stomach; for, though in him the face be "sicklied o'er with the pale cast of thought," yet it is most frequently an indication merely of disorder which admits of cure, and even if continued, may not at all shorten life.*—(*Armstrong*, op. cit., p. 63.)]

GENUS VI.

COLICA.

COLIC. BELLYACHE.

GRIPING PAIN IN THE BOWELS, CHIEFLY ABOUT THE NAVEI, WITH VOMITING AND COSTIVENESS.

THERE are various diseases to which this definition will apply; but which nevertheless

* The learned author and his able editor, when treating of dyspepsy, might have enlarged with practical utility on the *symptomatic* form of the disease, which arises mainly from causes distinct from the seat and functions of the digestive apparatus. One of the most frequent causes of dyspepsy occurring in females is a deranged function, or a disordered condition of the uterine system. The close connexion between a disturbed state of the uterine economy and a diseased action of the stomach is indeed well known; but this frequent source of dyspeptic evil is too often overlooked or disregarded.—D.

differ from each other in several particulars. M. de Sauvages thought these particulars of so much importance as to justify him in advancing each of these complaints to the rank of a distinct genus, under the names of gastrodynia, colica, rhachialgia, and ileus. Dr. Cullen, however, judged differently and more correctly. He regarded their distinctions as of subordinate moment, and in their prominent symptoms traced so close a resemblance as to indicate their being a sort of natural tribe or family; and he has, consequently, simplified them into one genus under the name here adopted of COLICA. In the ramifications of his species, however, he seems a little too diffuse, and he has unnecessarily, and somewhat capriciously, varied a few of the ordinary specific names, as those of ILEUS and RHACHIALGIA, which, for reasons assigned in the volume of Nosology, are here restored. In other respects, the present arrangement does not especially differ from Dr. Cullen's classification. The species that seem fairly entitled to attention are the following:—

- | | |
|---------------------|--------------------------------------|
| 1. Colica Ileus. | Iliac Passion. |
| 2. ——— Rhachialgia. | Colic of Poitou, or Painter's Colic. |
| 3. ——— Cibaria. | Surfeit. |
| 4. ——— Flatulenta. | Wind-Colic. |
| 5. ——— Constipata. | Constipated Colic. |
| 6. ——— Constricta. | Constrictive Colic. |

SPECIES I.

COLICA ILEUS.

ILIAC PASSION.

GRIPING PAIN, VOMITING, AND COSTIVENESS, ACCOMPANIED WITH RETRACTION OF THE NAVEI, AND SPASMS OF THE MUSCLES OF THE BELLY.

THE name of Ileus (ἰλεος or εἰλεος, for it was written both ways) is entitled to veneration, as it has descended to us from the earliest Greek writers, who thus denominated it, either from that intorsusception or convolution of the intestinal tube which so often accompanies the disease, and which is the direct meaning of the term; or from the ileum, or small intestine, in which the disease is principally or most usually seated. Sauvages, and nearly all the continental writers, continue the term. Dr. Cullen has exchanged it for spasmodica, as an adjunct to colica; but from the comment to the Nosological Synopsis just referred to, it will be seen that he has gained nothing hereby, either in regard to precision or elegance.

The griping pain or bellyache in this species is very acute, and the vomiting is accompanied with a discharge, not only of bile from the duodenum, but of stercoraceous matter from the large intestines, or of injections introduced into the rectum; forcing their way through the strong muscular valve of the colon, which we have already noticed as being formed by a natural prolapse of the ileum, for the purpose of preventing a regurgitation of the feces into this last intestine; and evidently proving a powerful inversion of the peristaltic action through the whole

or nearly the whole length of the intestinal canal. While the obstinate costiveness which attends at the same time, pretty clearly indicates a spasmodic constriction, though rarely producing a total occlusion, of that part of the canal where the pain is most violent, often, indeed, extending to other parts, and even to the bile-ducts. And in this last case, even where the feces are discharged by the mouth, they are untinted with bile, while all the symptoms of jaundice supervene.—(*Bartholin, Hist. Anat.*, Cent. v., 62; *Ephem. Nat. Cur.*, Dec. i., Ann. iv. v.) The morbid action is, indeed, not unfrequently so violent as to excite inflammation over a considerable part of the intestine chiefly affected; and consequently to aggravate all the other symptoms.

And hence the disease is presented to us under the two following varieties:—

- α *Fæcosa.* The vomiting accompanied with feces or substances injected by the anus.
- β *Inflammatoria.* Accompanied with symptoms of inflammation.*

The dissection of persons who have died of either of these varieties has shown us, in some cases at least, that one portion of the affected intestine, constricted and lessened in its diameter, has fallen into another portion below it, and thus produced what is called an *INTROSUSCEPTION*, or involution of its coats. The fact is not difficult to be accounted for; and it will readily explain the cause of the great torture which is often suffered under the influence of this grievous malady. In every case in which the intestinal tube is weakened, there is a very copious extrication of air, producing in many instances a palpable distention of the parietes of the abdomen. In ileus, however, there is also, as we have already observed, in conjunction

with this, a strong inversion of the peristaltic action operating from the rectum to the stomach, and forcing back whatever recement or other materials are co-acervated in any part of the intestines. These, by intermixing with the elastic vapour of the intestinal tube, become very voluminous, and distend it to its utmost range wherever distention can be accomplished. In one or more parts, however, of its entire length, we have also seen that there is a violent spasmodic constriction, through which the distensive force cannot prevail, excepting perhaps by snatches, or during a remission of the spasm. The two powers are hence brought into immediate contact; and while the gut is in consequence rigidly contracted above, it is widened almost to bursting below; and, during the struggle which ensues, a part of the imprisoned contents of the expanded intestine is forced upwards, and the collapsed portion of the superior intestine at the same time slides downward at the point of the stricture.*

* It is admitted by Dr. Abercrombie, that, in a fatal case of ileus, we generally find one part of the intestine in the state of distention, and another part empty and collapsed, presenting nearly the form of a cord. However, he considers the doctrine of spasm in this subject entirely gratuitous. The collapsed state of a portion of the bowel, he regards as the natural state of healthy intestine, when empty. On the other hand, he adverts to several facts to prove, that a state of uniform distention, with lividity, may occur as a primary disease of the intestinal canal, without any appearance of obstruction, and without any part of it being in a contracted state. In ileus, the collapsed parts, he says, are commonly found in a healthy condition; the morbid appearances, whether inflammation, lividity, exudation, or gangrene, being almost entirely confined to the distended parts. According to Dr. Abercrombie's views, the causes of ileus are referable to a primary diminution, or destruction of the muscular power of a portion of the canal, and impediments to its action: the consequence of which is, that a part, at first healthy, becomes impaired. Under the effects of this interruption, primary destruction or diminution of the muscular power of a portion of the intestinal canal seems to take place from the poison of lead, and also in enteritis, where the bowel is distended, without any obstruction in the parts below. Interruption to the action of a portion of the canal, giving rise to distention, and consequent impaired action of the part above, is exemplified in hernia, contraction and adhesion of the intestine, accumulations of fecal or undigested matter in the bowels. However, Dr. Abercrombie admits, that, in some cases, there may be an irregular or morbid contraction of a portion of the canal, and that this may sometimes prove the first step in that chain of derangement of the harmonious action of the canal, which leads to an attack of ileus. At the same time, he regards the doctrine of spasm as in a great measure conjectural.—(*Op. cit.*, p. 149—151.) However, several good practitioners do not follow Dr. Abercrombie on this subject. Thus, Dr. Elliotson conceives that opium may frequently do good by alleviating the spasm.—(*Med. Gazette for 1832-3*, p. 551.) The occasional vomiting of feculent matter in colic appears to indicate a reversed order of the peristaltic action of the intestines. Drs. Whiting and Tweedie observe, that although Dr. Abercrombie calls in question the spasm of the

* In a pathological point of view, the disease resolves itself into three leading modifications, pointed out by that able physician, Dr. Abercrombie:—
1. Simple ileus, without any previous disease.
2. Ileus, with previous disease of such a nature, that it acts by deranging the muscular power, without mechanical obstruction.
3. Ileus with mechanical obstruction.—(*See Pathol. and Pract. Researches on Diseases of the Stomach, &c.*, p. 112, ed. 2.) Colic may be distinguished from enteritis by the absence of fever, the pain being generally relieved by pressure, the aspect of the countenance, and the quiet soft pulse. However, in an advanced stage, inflammation may supervene. When the symptoms of colic arise from a hernia, the protrusion will generally lead to its detection. Many diseases, being accompanied by sympathetic vomiting, may be mistaken for colic. Renal or biliary calculi may excite such vomiting; but the former case is characterized by pain in the back, and along the groins to the testicle and thigh, and disorder of the urinary functions; and the latter by a disturbance of the functions of the liver, and pain in the situation of the gall ducts. Besides, in neither of these diseases is there the same obstinate constipation as in colic.—*See Whiting and Tweedie, in Cyclop. of Practical Medicine*, art. *COLIC*.—Ed.

In the midst of this spasmodic commotion there is also another extraordinary change which has been sometimes found to take place in the relative positions of different parts of the intestinal tube. For from the urgency of the moving power that works upwards, the natural effect of the gravitating power that works downwards, and the looseness of the convoluted canal itself in many parts, and its tightness from adhesions in others, it has sometimes become twisted into nooses and knots; in which the portion forming an encircling cord or bridle has been drawn so tight as to produce strangulation, and render gangrene inevitable.* In one instance, indeed, the spasmodic action was so extreme, that the bridle not only produced strangulation and gangrene, but cut through all the coats of the intestine on the opposite side to the mesentery, and made an opening of about an inch in length. —(*Med. Observ.*, vol. iv.)

Generally speaking, however, there is more danger in the second variety than in the first: the symptoms, if not early opposed, are more rapid in their progress, and gangrene is produced in a shorter period of time. Yet when an active and well-discriminated course of treatment is pursued, the inflammation is very frequently subdued, and the patient escapes without further injury.

It is a singular fact, that though ileus is no uncommon result both of intussusception and inflammation, it sometimes takes place without either of them, or at least without intestinal pain or other manifest symptoms of inflammation or spasm; for which we have the authority of Stoll (*Ratio Medendi*, viii., 129), Haller (*Comment. Nova. Gotting.*, viii., 1), and Morgagni.† Even where inflammation exists, it is not difficult to distinguish the disease from enteritis, by the spasmodic contraction of the abdominal muscles that accompanies it, the diminution of pain which ensues upon pressing the abdomen,‡ and the small degree of fever which

is present, compared with that by which enteritis is usually characterized.

Both varieties of ileus are apt to run into each other, and the disease assumes the first or the second form from the patient's idiosyncrasy, the peculiar condition of the organs affected at the time of the onset, the temperament of the season, or some other adventitious circumstance. The causes, therefore, for the most part, are alike, and very numerous. The more common are, acrid, cold, or indigestible esculents; cold beverages on a heated stomach; catching cold in the feet or abdomen; exposure to wet during the flow of the catamenia; unalimentary substances swallowed through bravado or by mistake, as knives, metallic money, or pieces of glass, plum, cherry, or other fruit stones; an excessive flow of bile probably of bad quality; worms; drastic purgatives in an over-dose, as scammony, black hellebore, and colocynth; calculous or other balls congested in the intestines and obstructing their passage, as scybala, bezoards, biliary calculi, and indurated feces; violent passions, or other emotions of the mind, as extreme rage or terror; intussusception, a diminished capacity of the intestinal canal from scirrhus or cancerous tumours, from internal hernia,* from an ossification, callosity, stricture, or coalescence of its internal tunic, [or from the difficulty with which the contents of the bowels sometimes pass that portion of the canal which lies near the situation of a previous artificial anus.†] It is also at times a consequence of transferred gout or rheumatism.

In the treatment of iliac passion, whenever there is inflammation, or a decided tendency towards it, evidenced by shivering or a full pulse, blood should be taken freely, and even repeatedly, from the arm, whether the patient be of a strong, robust, or of a delicate and weakly constitution. It is a practice, indeed, recommended generally by many writers in the commencement of the disease, even where no inflammatory action exists, with a view of relaxing the spasmodic constriction; but, in these cases, it is not absolutely called for, and, where the habit is weakly, is likely to produce more harm than good.‡

muscular fibres of the intestines, he cannot be said to have proved this point; he has, however, made it clear, that in many instances where colic has been supposed to arise from spasmodic contraction of some part of the bowels, it ought to have been referred to another cause.—Cyclop. of Practical Medicine, art. COLIC.—Ed.

* *Mém. de l'Acad. Royale*, xxiii. par M. de la Peyronie. Also several cases in Abercrombie's *Pathol. and Pract. Researches on Diseases of the Stomach*, p. 119—125, 2d edit.—Ed.

† De Sedibus, &c. xxxv., 19, 21, 23. In one fatal case, noticed by Dr. Abercrombie, the only changes found on dissection were, a softened state of a part of the right lobe of the liver, and a great and uniform distention of the small intestine, without any appearance of inflammation.—Ed.

‡ Some examples on record do not correspond to this account; thus, in one case related by Dr. Abercrombie, the pain was increased by pressure at the very commencement of the attack, even before any inflammation can be supposed to have existed; and, after death, merely a superficial blush of vivid redness was noticed, without any appearance of exudation.—See *Pathol. and Pract. Researches on Diseases of the Stomach, &c.*, p. 114, ed. 2.—Ed.

* On the autopsy of a case of ileus terminating in enteritis, Dr. Francis observed a remarkable deviation from the normal structure; a portion of intestine extended from the ileum to the umbilicus, forming a diverticulum of the ileum. For the details of this curious case, with a plate, see *Am. Med. and Phil. Reg.*, vol. i., p. 38.—D.

† See Abercrombie, *op. cit.*, p. 126.—Ed.

‡ Ileus sometimes terminates in inflammation: this is one important reason for bleeding, when not forbidden by the patient's age, or the state of his constitution. Besides this obvious fact, Dr. Abercrombie believes there is a modification of the disease, depending upon inflammation limited to the muscular coat; here also blood-letting seems to him an important remedy; and the fact is familiar to every practical man, that the relief is often so immediate, that there is no time to raise the patient out of bed, or scarcely to tie up the arm, before complete evacuation takes place.—(Abercrombie, *op. cit.*, p. 159.) The best modern

The two next points to be aimed at are, a removal of the griping or spasmodic pain, and a restoration of the intestines, from a state of inverted action, to their proper peristaltic motion; and hereby a resolution of the costiveness.

For the first, humid heat in the form of a warm bath, warm fomentations, and warm and copious clysters, afford a rational chance of success. The last should be rendered emollient by a solution of oils, and moderately loaded with purgatives, so that both intentions of cure may be carried forward at the same time. In combination with these, opium may also be tried, and various other narcotics; and especially the extract of hyoscyamus, which in many instances evinces an aperient as well as narcotic power. [The introduction of tobacco-smoke, or the infusion of the plant into the rectum, is frequently of service. Dr. Abercrombie regards the tobacco injection as the remedy of most general utility in all forms and stages of ileus: fifteen grains are to be infused for ten minutes in six ounces of boiling water; and an hour after the injection of this quantity, if no effect has been produced, twenty grains may be infused, and their power tried; and so on, until slight giddiness and muscular relaxation show that the peculiar action of this narcotic is taking place. If the case should not now yield speedily, Dr. Abercrombie recommends the clyster to be repeated every hour, or every two hours. With this means he associates full doses of mild purgatives, such as aloes and hyoscyamus, every hour or two. Also, if the patient be of a full habit, the pulse be rising, and a fixed pain or tenderness be complained of in any part of the abdomen, Dr. Abercrombie has recourse to one or two bleedings.—(*Researches on Diseases of the Stomach, &c.*, p. 159, ed. 2.)] If the opium be employed in the form of a tincture, the dose should be from a hundred to a hundred and twenty drops in an injection of four ounces of warm olive-oil. If hyoscyamus be had recourse to, we may safely use either the seeds or the extract; about four or five grains of the former, and ten of the latter, may be added to each injection. Clysters of a strong decoction of poppy-heads have also frequently been found highly beneficial.* And to these should succeed the application of stimulants to the belly, as ammonia, or blisters. Sir John Pringle speaks highly of the latter, and not without reason; for, if made sufficiently large to be active, they often succeed, not only in quieting the spasm, but in obtaining evacuations, after injections, purgatives by the mouth, fomentations, and opiates have been tried without effect.

physicians certainly seem to be more in favour of venesection than Dr. Good.—Ed.

* Colic may arise from hardened feces in the rectum, and hence another reason, very properly insisted upon by Dr. Elliotson, for the invariable use of a clyster, who prefers one composed of three ounces of oil of turpentine, blended with a pint of gruel or other fluid. Sometimes the removal of indurated feces from the bowel with the handle of a spoon becomes necessary.—See Lect. in Med. Gazette, for 1832-3, p. 551.—Ed.

Purgatives for the second intention, and combined with antispasmodics, should, in like manner, be attempted by the mouth; though the vomiting is sometimes so incessant that we can get little or nothing to stay on the stomach. But the attempt must be made, and steadily persevered in. Calomel, in free doses of about four grains to a dose, will usually be found the best aperient medicine. It occupies the smallest space, and in the form of a pill, has the fairest chance of being retained. If repeatedly rejected,* it must be combined with opium, which nevertheless has a tendency to retard its action; but as the opium may mitigate the spasm and diminish the pain, it will commonly be found a useful adjunct, and a grain or two of it may be given every six hours. Calomel, however, though sure, is slow in its operation; and should hence, where the stomach will bear it, be united with some other and brisker aperient. Of these the neutral salts seem to answer best; but if they cannot be retained, we must exchange them for tartrate of potassa, which is less likely to be thrown back. It is seldom that the drastic purgatives can be recommended; because, if they do not succeed, they are apt to excite inflammation where it does not exist, and to increase it where it does.†

[One modification of ileus yields to a full dose of opium sooner than to any other treatment. Such case seems to Dr. Abercrombie (op. cit. p. 160) to be chiefly characterized by paroxysms of violent tormina, and, if these are accompanied by frequency of pulse, and fixed pain or tenderness, he deems a free bleeding, followed by an opiate, a successful practice. At the same time, he expresses a preference to the treatment with tobacco injections, as generally safer than the employment of opiates.]

The relief derived from the symptom of vomiting has led some practitioners to prescribe emetics; but the benefit hence obtained is very transient. I do not mean to say that they have never been serviceable; but they cannot be relied upon except in special cases, and have oftentimes aggravated the spasm.

Dr. Cullen, on the advice of De Haen, recommends a stream of warm water to be thrown forcibly and with a proper syringe into the rectum, so that it may play like water from an engine upon the constricted portion of the intestine; and declares that he has found this remedy to be one of the most effectual.‡ When

* In cases where purgatives have been rejected by vomiting, a small portion of the cuticle may be removed by a blister; after which, the application of one or two drops of croton-oil to the part, will commonly purge.—D.

† Dr. Elliotson does not seem to be intimidated by this doctrine; for, after giving scruple doses of calomel, and finding that this medicine remains in the stomach, he prescribes a strong dose of castor or croton-oil, and Epsom salts. In one severe case, he gave with success a drop of croton-oil every hour or half hour, till the desired effect had been produced.—Op. et vol. cit., p. 550.—Ed.

‡ In the Glasgow Medical Journal is a case, in which the inflation of the intestines with common air gave relief.—Ed.

the ordinary means, and particularly those of warm injections and the warm bath fail, some practitioners have been courageous enough to try cold applications both external and internal. Sir George Baker tells us, that a physician of credit informed him he had once prescribed the cold bath with success. And Citois affirms, that, in several species of colic, this was his constant practice, even in the midst of winter, and calls upon all his fellow-citizens to attest, that most of his patients thus treated had been restored to health.* Saccassani relates (*Epist. v. Haller, Bibl. Med., Pr. iii., p. 601*) the case of a person instantly cured by drinking a large draught of cold water. Zacutus Lusitanus narrates the history of a patient who speedily got well by being rolled in snow.—(*Prax. Adm., lib. ii., obs. 23.*) But these are extreme instances; and, notwithstanding an occasional success, the practice is not to be depended on. It will prove most effectual where the colic is accompanied with, or produced by, hysteria. While, on the contrary, where it has been occasioned by too violent doses of drastic purgatives, warm stimulants, as the oil of turpentine, and even brandy (*Clossius, obs. 27*), have been taken with great advantage.

Dr. Percival, Dr. Warren, and various other writers, upon their authority, advise that the antispasmodic plan, whether by the stomach or the rectum, or both, should take the lead, and the purgative plan follow. This will always be found the proper order in attacking the painter's colic: but we should lose much important time, and often allow the inflammatory symptoms to get fatally ahead, if we were to adopt this as a general rule in iliac passion; in which the symptoms, if not more dangerous, are more urgent, and demand a more rapid march of treatment. [After the explanation given of the numerous and very different circumstances exciting or accompanying ileus, it requires but a slight effort of the understanding to know that the treatment ought not to be conducted in any particular way in every example of the disorder. Hence Dr. Abercrombie points out three varieties of ileus: one case, characterized by obstinate costiveness, distention of the abdomen, and considerable general uneasiness, but without tenderness, or much acute suffering. Another case, where the same symptoms are combined with fixed pain and tenderness, referred to a defined space on some part of the abdomen. A third case with violent attacks of tormina, occurring in paroxysms, like the strong impulse downwards from the action of a drastic purgative—the action proceeding to a certain point,

there stopping, and becoming inverted, followed by vomiting, the vomiting often feculent. Dr. Abercrombie thinks that these distinctions seem to denote the propriety of differences of treatment, according as the symptoms may indicate a deficient action in the canal, or one in which there is violent action limited to a certain part of it, though ineffectual for overcoming a derangement which exists in a lower portion of the tube. The practical application of the distinction refers chiefly to the use of purgatives in ileus. "There are some cases," says Dr. Abercrombie (*op. cit. p. 158*), "which yield at first to a powerful purgative; and others, in which an active purgative is highly and decidedly injurious. A large dose of calomel will frequently settle the stomach and move the bowels; but upon the whole, I think the best practice in general is the repetition, at short intervals, of moderate doses of mild medicine, such as aloes combined with hyoscyamus. The peculiar and intricate character of the disease appears very remarkable from the fact, familiar to every practical man, that there are cases which yield to a full dose of opium, after the most active purgatives have been tried in vain."]*

SPECIES II.

COLICA RHACHIALGIA.

COLIC OF POICTOU. PAINTER'S COLIC. DEVONSHIRE COLIC.

THE PAIN AT FIRST DULL AND REMITTING; BUT PROGRESSIVELY GROWING MORE VIOLENT AND CONTINUED: EXTENDING TO THE BACK AND ARMS, AND AT LAST PRODUCING PARALYSIS.

From the pains striking through to the back, Astruc first distinguished this species by the name of RHACHIALGIA (*ῥαχιαλγία*), literally, "back-bone-ache, or spine-ache;" and as the term is highly expressive, and has been continued by most of the continental writers, it is retained as a specific name in the arrangement before us, notwithstanding that it has been dropped, or varied, or exchanged for some other, by several writers of our own country.†

The pain is most commonly seated, from the beginning to the end of the attack, at the pit of the stomach. It is at first dull, but gradually grows more severe; and, as it increases, extends upwards to the arms, and downwards to the navel, back, loins, rectum, and bladder;.

* Dr. Eberle mentions (*Practice of Medicine*, vol. ii., p. 338) a case of ileus, in which several inches of the intestine sloughed off, and passed away by stool. New adhesions formed, and the patient recovered. In the same work we find a reference to a case, where, "other remedies failing, the Cæsarean operation was performed, the invaginated intestine drawn out, and a perfect cure obtained."—D.

† According to Dr. Monro, the pathognomonic symptoms of painter's colic are, the acute twisting pain about the navel, not increased by pressure; the dragging inwards and hard feel of the abdominal parietes; tenesmus; and obstinate costiveness.—*Morb. Anat. of Human Gullet, &c., p. 246.*—R.D.

* F. Citesii *Opuscula Medica*, p. 215. "When every thing has failed, I have known this affection of the bowels overcome by taking the patient out of bed, and dashing two or three pails of cold water upon the abdomen."—(Professor Elliotson's *Lectures, Med. Gaz., 1832-3, p. 551.*) Dr. Abercrombie has repeatedly tried the method of raising the patient into a standing posture, and dashing cold water about his legs; but no benefit resulted from it.—(*Pathol. and Practical Researches on Diseases of the Stomach, &c., p. 160, ed. 2.*)—E.D.

and frequently to the thighs and legs. From the navel it sometimes shoots with so much violence to each side, that the patient feels, and so expresses himself, as if some person were cutting him in two. Almost all the external muscles are rendered sore by the great violence of the pain, as though they had been affected with rheumatism, and can scarcely bear the weight of the bedclothes, or the slightest touch of a finger. Sometimes, however, the seat of pain alternates between the stomach, which nevertheless, as just observed, it never entirely quits, and the external muscles: it is violent in the stomach, while the lower bowels and the external muscles are at ease; or it nearly quits its hold on the stomach and lower bowels, and rages through the external muscles. Sickness is an early symptom, as well as costiveness; and as the pain in the stomach increases, the sickness increases also; even on the second day from the attack, the retchings are violent, and the discharge thrown up consists of acrid slime and porraceous bile. A momentary relief is hereby usually obtained, and the patient flatters himself that he is about to recover. Too soon, however, does he find himself disappointed: as long as the pain continues, the same morbid matter is secreted, and thrown into the stomach; and the retchings return with perhaps accumulated violence: or, if they do not, their place is supplied with bitter eructations and hiccoughs. The pulse, notwithstanding the severity of the sufferings, is little affected at first, and for several days continues as quiet as in health. After the fourth or fifth day, however, it sometimes becomes quicker, but not always: and it may admit of a question, whether the acceleration be not even at this period rather the effect of the medicines taken to procure relief, than of the disease itself.—(*Dr. Warren, Med. Trans.*, vol. ii., p. 72.) [The skin, though generally cold and damp, is occasionally rather hot; but there appears to be no tendency to inflammation.] The urine varies so much in different individuals that no stress can be laid upon it. [In some cases, the sphincter muscles of the bladder and anus are so contracted, that the urine and feces cannot be voided, and a clyster-pipe is difficult of introduction.—(*Monro*, op. cit. p. 246.) Towards the close of the disease, there is generally a pain round the edges of the feet and at the extremities of the toes, which are often red and swollen, and to appearance gouty. Relieving sweats break forth, sometimes accompanied with an efflorescence. About the same time, a griping of a different kind from what has hitherto been endured, and which is more easily bearable, takes place, attended with a disposition to go to stool; and after large discharges of various kinds of excrement, frequently of scybala or hard lumps, in shape resembling sheep's dung, together with black and dirt-coloured slime, occasionally mixed with blood, the patient is perfectly relieved. After several attacks of this disease, a paralysis commonly affects the fingers, or the whole hand and fore-arm, so that the former become contracted, and the hand, when the arm is extended hori-

zontally, hangs at a right angle to the arm, the extensor muscles being in both cases more paralyzed than the flexors. The palsied limb shrinks very much; and the muscles lose not only their natural size, but also their natural structure, being converted into a suety substance (*Monro*, op. cit., p. 247), or a soft pulp.*

Some writers represent the bowels as exhibiting after death a remarkable diminution in their diameter; some have met with invaginations; and others have found the bowels red and more or less injected. All these appearances seem, however, to be accidental, and not to constitute any essential part of the disease; for, in the first place, they may exist without being attended with symptoms of colic; and, in the second, persons die of the latter disease, and yet when their bodies are examined, no morbid appearances of the above description can be traced. M. Andral has published the details of several cases, in which no vestiges of disease could be detected in the alimentary canal after death, and similar facts are recorded by M. Louis. Neither could M. Andral find any defect in the brain and spinal marrow; and yet serious degrees of palsy had taken place.†]

In a mild degree, and under the best therapeutic plan, the disease can seldom be removed in less than five or six days; but if it be violent, neglected, or ill-treated, it will continue for weeks, or even months, with now and then a truce for a few days; and will terminate in the above peculiar sort of palsy of the upper extremities; or in death, preceded by deafness, blindness, delirium, or epileptic fits.

The remote cause appears in almost every instance to be lead introduced into the system, either by the stomach, the lungs, or the skin; and hence the disease is found most frequently in those countries, and under those circumstances, in which this metal is most freely used or most readily dissolved. In the neighbourhood of smelting furnaces, pigs, poultry, and other animals evince the same complaint. Thus, too,

* Dehaen gives a remarkable instance of a softening of the muscles in a person who was attacked by paralysis of the upper extremities, in consequence of colica rhachialgia. The muscles of the limbs, though capable of slight contraction, were converted into a substance as soft as pulp. After the removal of the paralysis, they recovered their usual consistence. Barthcz mentions a case in which, under similar circumstances, the two deltoid muscles were softened in the same extraordinary degree; but returned to their natural condition after the paralysis had been cured. It is well known to pathologists, that, when the muscles of animal life have been long in a state of inactivity, they always grow pale, and lose their proper firmness.—See Andral, *Anat. Pathol.*, t. i., p. 220.—Ed.

† See Andral, *Anat. Pathol.*, t. ii., p. 210. "If," says this distinguished pathologist, "there be one fact established in medicine, it is, that the lead colic is not an inflammation." He considers it to be a neurosis, in which the spinal marrow and abdominal plexus of the great sympathetic nerve are affected. He refers the constipation either to an annihilation of the contractile motion of the intestines, or a suspension of their mucous secretion.—(*Clinique Méd.*, t. iv., p. 506.)—Ed.

in Poitou and Devonshire, in which lead was formerly employed to destroy the acidity of the weak wines and ciders for which these provinces are celebrated, it was at one time so common as to obtain the name of Devonshire colic, and colic of Poitou. And hence house-painters, whose occupation leads them to a constant use of lead, and who are often too little attentive to personal cleanliness, are to the present hour so frequently affected by it, as to give it the still more general name of painter's colic. Plumbers, potters, glaziers, workers in glass, gilders, chymists, miners, and printers, are, in like manner, exposed to its attack, from the large quantity of lead contained in the materials they are continually handling. I attended some years ago a printer, who had several times been afflicted with this disease, but had fortunately recovered from every attack, though each return proved severer than the preceding. The cause had never been suspected till I pointed it out to him, by inquiring whether, after leaving the printing-office, he was careful to wash his hands before he sat down to his meals; to which he replied, that he had never been put upon his guard on this subject, and had, therefore, never attended to it. I rigidly enforced upon him the necessity of doing so, and he continued for six or seven years without the slightest return. At this period he again grew careless and confident; he again suffered, and lost his life.*

[The power of lead to excite colic and paralysis has been long known, these effects having been frequently traced to the accidental or designed use of the metal as medicine, or in the food and drink. During the sixteenth and seventeenth centuries, when preparations of lead used to be given in large doses medicinally, the colica pictorum and paralysis, in their severest forms, appear to have been very frequent. Nevertheless, it was not until the investigations of Sir George Baker were published, that the poison of lead was suspected even to be the common, much less the exclusive cause of colica pictorum. In countries where the disease was endemic, it was attributed to a free use of the sub-acid wines, or other acidulous liquors, peculiar to the respective districts with which, in fact, it was very obviously connected. In the West Indies, the endemic colic, called the dry bellyache, is observed to be the consequence of drinking freely of newly-distilled rum: and this liquor is therefore universally considered as the cause of the disease. Andral remarks, that an assemblage of symptoms, corresponding in every respect to colica pictorum, may arise from sudden and continual changes of temperature, as happens at Madrid; and also from causes which primarily affect the nervous system. "The origin of some other cases," he says,

"baffles investigation. The positive reference of this form of colic in every instance to the action of lead, seems therefore not quite warranted."*]

Lead, under some modification or another, is now considered to be the real cause of this species of colic. The cider of Devonshire produced the disorder much more frequently and extensively than that of other counties, as of Herefordshire; and the wines of some districts on the continent excited the disease, when similar wines of other districts did not. Sir George Baker ascertained, that a small quantity of lead was employed in several of the mills, in which the apples were bruised for the manufacture of cider, to fasten the iron cranks which connected the stone-work. It is well known, too, that in several countries on the continent, the practice of sweetening the wines with litharge, and other preparations of lead, was very common, and that, in these districts, the colic was particularly prevalent. Dr. Mosely was cautioned by Dr. Menghin, of Inspruck, to avoid all sweet wines whatsoever, but particularly the common tavern wines, upon the road in the Tyrol and in Italy. He never deviated from this advice but once, at Viterbo, and then he paid dearly for his indiscretion.—(*Treatise on Tropical Diseases*, p. 527.) Colica pictorum is very prevalent in this metropolis and other large towns; yet Dr. Bateman never saw an instance which was not decidedly traced to the operation of lead. A great proportion of house-painters and plumbers, he observes, have the disease at some period of their lives; and, in particular constitutions, a very minute quantity of lead will bring it on. Dr. Fothergill has recorded several cases, in which it took place in persons who painted in water-colours, and were in the habit of pointing the pencil in their mouths. In addition to these facts, it deserves notice that, in many specimens of cider, which were analyzed by Sir G. Baker, a small portion of lead was detected. And in the new rum of the West Indies, which excited the colic throughout several regiments, while others were totally free from it, Dr. Hunter discovered by analysis the presence of lead. After a time, the lead appears to be deposited, and then the rum loses its noxious quality.†]

The question was next started, and it has been started again in our own times, whether pure water, as well as acid wine, be not capable of dissolving lead in a metallic state; and, consequently, whether the community be not daily running a great risk of being poisoned by employing this metal in pumps and reservoirs? The public mind was for a long time agitated by this discussion, and Dr. Percival thought it right to institute a variety of nice experiments to allay the general apprehension, by showing that pure water is not in any respect a solvent of

* The distinguished Franklin, originally a printer, first pointed out this affection (*Phil. Works*, vol. iii., p. 399) as occasionally occurring among these *men of letters*. It would be well for this valuable class of operatives to pay due regard to the cautions in the text. Cases of colica rhachialgia and of partial paralysis can sometimes be traced to no other cause.—D.

* See Andral, *Anat. Pathol.*, t. ii., p. 210; and a *Memoir* by M. Pascal, in *Journ. de Méd. Militaire*.

† See *Med. Trans.*, vol. iii.; and *Med. Obs. and Inq.*, vol. v.; and art. COLICA, in *Rees's Cyclopædia*.

metallic lead.—(*Obs. and Exp. on Lead*, 1767.) Yet it was a course hardly necessary, since the daily use of lead in water-cisterns, by upwards of a million of inhabitants in this metropolis, without any inconvenience whatever, was then, and still continues to be, the most decisive and satisfactory proof that can be afforded of the insolubility of metallic lead in rain or river-water. Even saturnine lotions applied to the surface of the body have rarely, if ever, been found deleterious, although these also were at one time suspected of being highly mischievous. They may perhaps prove so in a few singular idiosyncrasies, but they do not affect mankind in general.

Lead, however, so minutely divided as to impregnate the atmosphere with its effluvium, has frequently laid a foundation for the disease. But whether any preparation under the form of cosmetics has proved injurious, I cannot undertake to say. The disease has certainly been produced by sleeping in newly-painted rooms, of which a striking instance occurred a few years ago to myself. The patient was a surgeon of highly distinguished character in this metropolis. When I saw him, at his particular request, he had been ill for a fortnight; and, the cause not having been suspected, his complaint was conceived to be obscure and anomalous. The symptoms, as they struck me, were evidently those of rhachialgia from lead; and upon pointing out to him my view of the case, I found that, about a month antecedently, he had sent the whole of his family into the country, as his house was about to undergo a thorough repair in painting, while he himself remained at home, and slept there. The cause was admitted and acted upon, but the disease had gained too much ground, and was immovable; his spirits became deeply dejected, and he fell a sacrifice in about two months from the attack.

In the Medico-Chirurgical Transactions is a case communicated by Dr. Badeley, in which the patient, a domestic in his own house, lost her speech and became paralytic from being only six hours in a newly-painted room, but quickly recovered from both upon being removed;* evidently proving the deleterious influence of lead in a state of vapour; and, at the same time, that, in different constitutions, it will show its effects upon different organs or in a different manner.

Sir George Baker asserts, that he has known the disease originate from minute corpuscles thrown off from the clothes which have been worn by plumbers while at work.—(*Essay on the Endemic Colic in Devonshire*, 1762.) And in corroboration of this remark, Dr. Reynolds observed, when he was physician to St. Thomas's Hospital, that the colic of all the workers in lead frequently returned, under any management whatever, while they were allowed to wear the clothes in which they had been accustomed to labour: on which account such clothes were

never suffered to lie on the patient's bed. Scntin (*Memorab.*, p. 114) was a witness of the same effect from hanging up labourers' wallets, filled with food for the day, in places impregnated with the vapours of lead. And the present author has occasionally met with other instances of the disease from an habitual residence in close damp rooms, filled with *newly-printed or coloured paper*: for the emanation of flake-white, which usually enters into the colour, seems to have the same power of affecting or being affected by the surrounding atmosphere, as that of lead in a finely attenuated metallic state.—(*Med. Trans.*, vol. iii., p. 420.)

I have said that pure water does not act upon lead in a metallic form,* but while we see lead thus easily disintegrated, and reduced to an oxyde or a carbonate by acids existing in the atmosphere, or even by the atmosphere itself, we may readily conceive that aerated waters are capable of decomposing it in a slight degree, and of forming oxydes or salts that may be injurious to the health. And hence, where lead is required in the form of reservoirs for waters of this kind, or for culinary vessels, it should, by all means, be united with tin in equal proportions, as recommended by M. Prout (*Annales de Chimie*, tom. lvii., p. 84), or with a slight surplus of the latter, as proposed by M. Vauquelin.—(*Id.*, xxxii., p. 243.) For first, tin is a harmless metal, as well in its salts and oxydes as in its reguline state, at least in any quantity in which we can conceive it possible to be swallowed by mistake. And, next, as it is more readily oxydable, and has a closer affinity for all the acids than lead, when united with the latter it must completely draw away all the acid it can come in contact with, and detach every atom of oxygen which might even previously have been united with the lead.

The paralytic effect produced by the action of lead is one of the most formidable symptoms to be encountered in the therapeutic process: in laying down which, our first efforts should not be different from those in the preceding species, excepting that, in an attempt to remove the spasmodic pain, opiates may be allowed to precede the use of purgatives. [Colica rhachialgia is attended with obstinate costiveness, and, therefore, one would be inclined to have recourse at once to the most active purgatives. The best physicians have differed, however, respecting the propriety of beginning with cathartics. Sir George Baker directs purgatives; Dr. Darwin and Dr. Warren opiates.—(*Zoonomia*, vol. ii., and *Med. Trans.*, vol. ii.) Dr. Bateman was also satisfied that, whenever colic could be decidedly traced to the operation of lead, the most effectual treatment is the administration of a large dose of opium, and repeated at short intervals until the pain and spasmodic stricture are relieved, after which the bowels may in general be easily opened, and the cure completed by tonics and cordials.—(Art. COLICA, *Rees's Cy-*

* Vol. ix., p. 238. See also Seguin, *Annales de Chimie*, lxxxviii., 263.

* Some late chymical analyses have shown the presence of a minute portion of lead in what is termed pure spring-water, when it has been retained for some time in leaden pipes or vessels.—D.

clapædia.) One of the latest and best writers on the subject, Dr. Pemberton, has recommended a union of castor-oil and laudanum. Dr. Cheyne has generally succeeded in relieving colica pictorum by following Sir George Baker's practice; yet occasionally he has found it necessary to give opium, and that too in large doses, particularly when obstinate vomiting occurred. Dr. Pemberton (*On Diseases of the Abdominal Viscera*) states that in some examples, opium itself will act as a purgative, as he supposes, "by resolving the spasmodic affection of the colon, by which the feces are locked up between its circular bands." And one critical writer recommends a large dose of opium with the same view, as after its exhibition the difficulty of procuring stools, he says, is not great.—(*Edin. Med. and Surg. Journ.*, vol. iii., p. 72.) With Dr. Cheyne, however, a doubt may be entertained, whether the costiveness be owing to spasm.* "From the termina we know that there is excitement in some part of the canal; from the vomiting we infer inverted peristaltic action; but from the obstruction we can infer no more than torpor of a particular part, and, judging from the symptoms which afterward occur, this torpor would appear to be paralytic." This view of the state of the canal enables us, without the aid of spasm, as Dr. Cheyne conceives, to understand how benefit results from opium. His plan is, to administer purgatives in the slighter cases, and opium with purgatives and stimulating clysters in the more severe ones.† Punctions to the abdomen, the warm bath, and emollient injections containing laudanum, are useful means; and venesection (See *Gregory's Elements of Physic*, p. 513, 2d, edit.), if signs of inflammation of any of the abdominal viscera be present.‡ In cases produced by the vapour of lead, Orfila says (*Toxicologie*, tom. i., p. 658), the antiphlogistic treatment should be abandoned.] The paralytic effect has been attempted to be subdued by the counteraction of other metals introduced into the system for this purpose: and especially mercury and silver. Both have, indeed, been given from the commencement of the attack by many practitioners; and,

* Dr. Cheyne's opinion on this point is corroborated by the statement of Professor Andral:—"The bowels," says he, "have been alleged to be strongly contracted in the lead colic, and their cavity much smaller than in the natural state; but my own observations enable me to declare, that nothing is more incorrect than this assertion."—*Anat. Pathol.*, t. ii., p. 119.—*Ed.*

† *Op. cit.*, vol. iv., p. 314. Dr. Elliotson does not particularly object to opium, provided it be briskly followed up by purgatives; yet he thinks that the latter answer equally well by themselves, without bringing on subsequent costiveness, which opium is likely to do. He begins with a large dose of calomel (one scruple), and then gives half an ounce of castor-oil every two hours, until motions have been procured.—*Ed.*

‡ In one of the earliest tracts which American medical literature can boast of, Dr. Cadwallader, of Philadelphia, about the year 1740, recommended mild cathartics and opiates for the cure of this disorder, instead of the then popular practice by drastics of quicksilver.—*D.*

as themselves relate, with great success. Dr. Warren and Dr. Biss were in the habit of persevering in the mercurial process till they obtained a salivation; and assert that they found the dull griping pain give way as soon as this was accomplished. The silver employed in rhachialgia has usually been in the form of its nitrate, or lunar caustic, to the amount of four or five grains in the course of the day. Dr. Roberts has published two cases of a cure obtained by this remedy; the one, that of a young, the other of an old man. The cases were both of considerable standing, and the joints of the wrists were weak almost to paralysis. Even this symptom, however, yielded by degrees. The salt was given from three to five grains at a dose, three times a day, in the form of pills: and in the last case five grains every six hours. It has the advantage of being a laxative as well as an antispasmodic: so much so, that a small quantity of opium was on this account added to the nitrate when given in its most frequent doses.—(*Med. Trans.*, vol. v., art. v.)

In treating of passive hemorrhage, we shall have occasion to observe, that whatever deleterious property the acetate of lead may possess, it is entirely removed by a judicious mixture of opium with it, so as in this state of union to become a most valuable styptic. It is possible that, under the form of an acetate, lead may be less injurious than under some others, for it has not unfrequently been given alone in the same complaint without any rhachialgic pains, where the bowels have been kept in a soluble state. But with opium every mischief seems effectually to be guarded against: and the beneficial influence of opium upon lead in this case should induce us to employ it, and that very freely, as an antidote in every case, and especially in the disease before us; and to counteract its constringency by a union with calomel. This rational practice, which has been pursued in our own country by several physicians, ever since Dr. Reynolds first called the attention of the profession to the corrective power of opium, when combined with lead in the case of hemorrhage, has now for many years been also tried with success in various parts of the continent. In France, the dose of opium has been usually only a grain or a grain and a half every night; but in Spain, as we learn from the memoirs of the *Real Academia Medica de Madrid*, a much bolder and more satisfactory employment of this medicine has been exhibited by a physician of distinguished judgment, Don Ignacio de Luzuriaga, who prescribed a grain of opium every three hours; and it will often be found necessary to augment this quantity.—(*Las Memorias de la Real Academia*, &c., Madrid, 1796.)

As the sulphate of lead is a compound insoluble in the stomach, and consequently altogether inert, M. Orfila ingeniously attempted to reduce the acetate and other preparations of this metal to the form of a sulphate, by giving large quantities of sulphate of magnesia; and he thinks he hereby succeeded in effecting a decomposition in the stomach of two dogs, upon which he made experiments to ascertain this

point, and in producing sulphate of lead in their stead. The experiments, however, proved fatal in both instances, though some portion of sulphate of lead seems to have been formed, and the death of the second dog to have been retarded. As the want of complete success may be ascribed to the want of a sufficiency of sulphuric acid in the re-agent employed, it would be better to try the experiment for the future, by giving the purgative salt in infusion of roses, or any other liquid adequately charged with the acid to answer the purpose; or by a free exhibition of the acid in a diluted state alone.

[Alum was at one time a popular remedy for painter's colic, but it has not maintained its ground; a fact rather against the efficacy of the sulphate of magnesia, as the merits of both depend upon the same chymical principle. Where, however, the colic arises from the presence of recently swallowed acetate of lead in the alimentary canal, and not from absorption by the skin, the method suggested by Orfila, with Dr. Good's improvement of it, seems the most promising of any of the plans hitherto recommended for counteracting the poison of lead. In confirmation of this observation, the editor begs leave to remind the reader of a statement made by Dr. Paris (*Pharmacol.*, vol. i., p. 338, 6th edit.), namely, that he has found, in the treatment of hæmoptysis, the effects of the acetate of lead quite invalidated by combination with alum, or by being prescribed with acidulated infusion of roses, or with small doses of sulphate of magnesia.]

The best purgatives, where the costiveness is severe, are those impregnated with the principle of camphire, as the essential oil of turpentine; and where these fail, the oil of croton in doses of one or two drops in the form of pills. [Dr. Elliotson sometimes has recourse to an injection of three ounces of oil of turpentine blended with fluid.*]

Two cases (*Dublin Hospital Reports*, vol. iv., p. 45) of violent painter's colic soon yielded to the application of tobacco stupes to the abdomen, followed by the exhibition of cathartic pills, with croton-oil, and of a purgative clyster. The introduction of tobacco-smoke into the rectum is proper in obstinate cases, taking care not to continue it too long when the pulse and powers of the constitution begin to sink. Sydenham extols this practice in high terms. Injections of an infusion of tobacco are said to have been first recommended in this disease by Lentin.—(*Mem. circa Aerem, vitæ genus, &c. Clausthalensium*. Götting. 1779.)

When all usual plans prove unavailing, the bowels may sometimes be made to act by dashing cold water on the legs and belly.

Colica rhachialgia, besides being attended with perils arising from obstruction of the intestinal tube, has also another source of danger by the inflammation of the bowels, with which it may become joined. From being a spasmodic

complaint, says Dr. Elliotson, or a paralytic one of the intestines (as others declare), it may become an enteritis. The symptoms are at first colic; the pain comes and goes; and there is no pyrexia; but, after a time, tenderness of the abdomen, fever, and all the marks of abdominal inflammation show themselves; and ultimately mortification. Hence the occasional necessity for leeches, and venesection; but unless the obstruction be removed, antiphlogistic treatment will not avail.]

Those who have had this disease are liable for a long time to fresh paroxysms; and the slightest exposure to the same cause will be sure to reproduce it; yet the appearances in different persons, as well afterward as during the attack, are extremely variable, from difference of idiosyncrasy; a correct idea of which may be best, perhaps, obtained from Dr. Warren's description of thirty-two domestics of the Duke of Newcastle's family, then residing at Hanover, who were all seized with rhachialgia, after having used, as their common drink, a small white wine that had been adulterated with some of the oxides of lead. They were all attacked in the common way, except one, whose first assault was an epileptic fit. This patient, as soon as the pain in the bowels which succeeded to the fit had ceased, had his head again affected, was troubled with a St. Vitus's dance, and died epileptic in less than a fortnight. Three were feverish from the beginning to the end of the disease. The rest were without fever till the fourth or fifth day, their pulse becoming quicker as the pain began to abate. In some the mouth was made sore by the acrimony of the matter vomited up. Four fell into a salivation for several hours every day, and said that their pain was abated during the spitting. Many had profuse sweats, and a few an eruption of red and white pimples just before the disorder terminated. One was delirious during a part of the time, but recovered. All relapsed within four or five days after they seemed to be cured. Some relapsed several times for several years. One only was rendered permanently paralytic and costive.—(*Med. Trans.*, vol. ii., p. 86.)

The most useful means of guarding against a paralytic diathesis, or of removing the paralytic sequel, where recourse can be had to them, are the Bath waters. And where the circumstances of the patient will not allow him to have the benefit of these, the spine may be advantageously rubbed night and morning with the warm balsams or resins dissolved in spirits;*

* M. Ranque, principal physician of the Hôtel Dieu at Orleans, in a memoir on the colic of Poitou (in *Archiv. de Méd.*, Paris, 1825), recommends counter-irritation on the abdomen, by means of a plaster containing camphire, theriac, hemlock, tartarized antimony, &c. He rubs every painful part with a liniment, composed of the aqua-lauro-cerasi, ʒij.; ether sulphuricum, ʒj.; and extract of belladonna, ʒij. He also administers twenty drops of an ethereal tincture of the leaves of belladonna, and ʒiv. of olive, or sweet almond-oil, as a clyster. The loins are covered with a plaster, two thirds of which are extract of hemlock, and one third emplastrum plumbi.—ED.

* Dr. Flint (*New-England Journal*) has cured a case of colica rhachialgia of long standing, by the oil of turpentine.—D.

and the common restorative process of air, exercise, friction, and tonic medicines should at the same time be had recourse to, and persevered in for many weeks, or even months, without remission. [The continued use of aperients has great effect in preventing a relapse.—(*Gregory's Elements, &c.*, p. 514.) It is obvious that the return of colica pictonum can never be effectually prevented, unless those avocations and beverages are relinquished which exposed the patient to the influence of the poisonous metal by which the disease was excited. A painter should also leave off the clothes in which he has been accustomed to work.

With respect to the paralytic affection of the hand and fingers, Dr. Pemberton found it much benefited by keeping these parts extended on a kind of handboard, splint, or battledoor. Blisters have also done good. M. Magendie recommends, for the removal of paralysis, the use of strychnine, which has been successfully tried by Dr. Graves.—(*Dub. Hosp. Rep.*, vol. iv., p. 46.) It may be given in the dose of one tenth of a grain, which may be increased to one eighth, three times a day. In one case, recorded by Dr. Elliotson, he tried this medicine and shocks of electricity; though he had seen benefit result from strychnine in other instances, the cure which followed in this example, is referred by him entirely to the electricity; first, because the dose of the medicine was only increased to one eighth of a grain, and no catching and tingling of the parts occurred, which are well known to be the first effects of this powerful remedy. After the sudden discontinuance of it, the cure also proceeded as rapidly with the electricity alone as with both means united.* Electricity he regards as one of the best local applications. He advises it to be applied every day, not only to the hand, but the forearm, and thinks he has seen sparks answer better than shocks.]

SPECIES III.

COLICA CIBARIA.

SURFEIT.

THE PAIN ACCOMPANIED WITH NAUSEA, HEAD-ACHE, AND DIZZINESS BEFORE VOMITING, AND AFTERWARD TERMINATING IN A GRIPING LOOSENESS.

I HAVE already had occasion to remark, that the stomach is one of the most capricious organs of the entire system; and hence we often find persons in an unsuspected state of health complaining, that even the ordinary meal to which they are accustomed sits upon it with a less degree of comfort and satisfaction than usual. And it is hence not at all to be wondered at that, when the stomach is overloaded with plain

food, and still more with high-seasoned dishes, and heady malt liquors and wines, the pain and sickness of colic should ensue, and that those organs which are in closest sympathy with the stomach, and particularly the head, should participate in the affection.

The same effect is not unfrequently produced by swallowing the husks, stones, or kernels of fruit with the fruit that is eaten, all which the stomach may at the time, or perhaps at all times, be incapable of digesting, and some of which have in a few instances remained so long as to germinate before their rejection; examples of which are given in the author's volume on Nosology.

When the stomach of the newborn infant is filled with any other food than its mother's first flow of milk, which is purgative, and removes the viscid meconium with which the alimentary canal is gorged, tormenting pains of a like kind follow: and if much air be extricated, the infant is overpowered with flatulence; and the present species becomes connected with the ensuing, and exhibits the oppressive distinction of wind-colic.

These are the common causes of the species before us, which is characterized by a greater or less intensity of the symptoms enumerated in the definition. But we often find it also originating after meals from causes that are more obscure, and with various other symptoms of a still more violent and distressing nature, as though the food itself had proved poisonous, or some poisonous substance had been intermixed with it. These additional symptoms are of two kinds: in the one, we meet with an intolerable sense of suffocation, the throat constricted, the face and eyes swollen, inextinguishable thirst, a burning heat all over the body, a quick small pulse, an intolerable itching or pricking in the skin, and an efflorescence on the surface, sometimes in the form of minute red millet-seed papulæ, sometimes in that of weals; twitching of the tendons, and a peculiar kind of delirium; the cuticle peeling off on the subsidence of the attack: the whole evincing great malignity of action, as though the cause were of a septic nature. Under the other set of symptoms, in addition to those noticed in the definition, we meet with great anxiety and difficulty of breathing, dejection of the spirits, spasms in the limbs, as well as in the abdominal organs and muscles, tenesmus, coldness of the extremities, loss of sight and hearing, convulsions, or coma.

The symptoms, however, vary considerably according to the general nature of the constitution. For the most part, they are sufficiently distinct; but in many persons they are strangely united; and the lethargy, tenesmus, or coldness of the extremities, may be combined with the cutaneous eruption. And hence esculent colic may be justly contemplated as ramifying into the three following varieties:—

a Crapulosa.

Common surfeit.

The symptoms indicating an overloaded stomach, and usually ceasing on the evacuation of its contents.

* See Clinical Lect. in *Lancet* for 1830-1, p. 333. But, notwithstanding the inference drawn from this particular case in relation to strychnine, Dr. Elliotson makes a more favourable report of the effects of the medicine in other instances of this paralysis, where he tried it. "This is a species of paralysis," says he, "where I have exhibited strychnine with decided advantage."—See *Med. Gazette* for 1832-3, p. 552.

- β Efflorescens. The symptoms evincing the action of some noxious, deleterious principle; the skin covered with an efflorescence.
- γ Comatosa. The symptoms evincing great nervous irritation, with a rapid exhaustion of the sensibility.
- Comatose surfeit.

In the FIRST OR SIMPLE FORM of the disease, the violence of the symptoms generally works its cure. But if the nausea should exist without vomiting, a simple emetic of ipecacuanha should be given to excite the stomach to a more perfect inversion of its action, which should be followed the next morning by a brisk purgative. In the colic of newborn infants, from viscid meconium, the purgative alone will be sufficient, and the best medicine for this purpose is castor-oil. If the congestion should proceed from an enfeebled state of the stomach, and too long a retention of the food in its cavity, it will be afterward requisite to put the patient on a course of stomachic or general tonics, of which we have taken a sufficient survey in the preceding description of dyspepsy.

It is possible that the SECOND VARIETY may occasionally proceed from a morbid irritability of the stomach operating upon a tolerably full meal of the most bland and innocuous viands; but it more generally proceeds from *animal* foods of a particular description, or eaten under particular circumstances, as comatose surfeit does from poisonous *vegetables* intermixed with common food. The animal substances that chiefly operate in the manner above described, producing a dreadful feeling of suffocation, swelling of the face and eyes, intolerable thirst, a burning heat on the surface, pricking or itching on the skin, succeeded by an eruption of some kind or other, and accompanied with the specific symptoms of griping pain, vertigo, and vomiting—are shellfishes, and fishes of a few other kinds, as muscles, which are perhaps the most frequent of all causes, some species of scallops and other coarse ostraceous worms, the land-crab (*cancer rusticola*), lobster (*c. gammarus*), conger-eel (*murana major subolivacea* of La Cépède), gray-snapper (*coracinus fuscus major*), and yellow-billed sprat (*clupea Thryssa*, Lin.), the baracuta, the kingfish, and several other species or varieties of scomber, as the bottlenose and ambar, the smooth bottlefish (*ostracion glabellum*), and the rockfish (*perca marina* of Catesby). There are also many others; but these are sufficient as specimens.*

As all these are among the edible productions of the ocean, and hence are eaten very gener-

ally as nutritious foods, it is a question of great importance, and which is yet open to discussion, what are the circumstances in which they occasionally disagree with the stomach, and produce the above symptoms?

It has been supposed by many pathologists that the mischief is occasioned by some poisonous property being conveyed into the body of the fish in the form of food; by others that it is the result of a change taking place in its general frame by the approach of the spawning season or some other period of life, or in consequence of its removal into a different climate; and by others again, that it depends altogether upon the idiosyncrasy or peculiar state of the constitution, or of the digestive organs of the persons that are thus affected.

[From an interesting paper by Dr. Combe of Leith, on the poisonous effects of muscles, we learn that muscles which had produced such consequences, and had been taken from a wooden bar in the wet-dock, had no very positive mark by which they could be distinguished from other muscles gathered elsewhere. His friend Dr. Coldstream was of opinion, however, that their livers were diseased, being darker and larger than natural. This disagrees with the investigations of Dr. Ferguson (*Edin. Phil. Journ.*, vol. i.), who arrived at the conclusion that the deleterious effects are not connected with any organic change in the animal; but, as Dr. Combe has remarked, some change may happen in the structure or secretions of the animal, beyond the sphere of our detection. The animals were quite fresh, and had no peculiar smell nor taste. The most delicate chymical tests gave no indications of cupreous impregnation; nor could a comparative chymical analysis of the poisonous and healthy fish, undertaken by Dr. Christison, discover any peculiar principle in the former, or any difference in chymical nature between them. The poisonous effects of the muscles gathered from the above wooden bar were not confined to the human race, a cat and dog having also been killed by eating them, though other muscles, gathered in the vicinity of the dock, were eaten by such animals with impunity.—(*Edin. Med. and Surg. Journ.*, No. 94, p. 86.) The supposition of a cupreous impregnation of the poisonous fish in the West Indies, has been ably refuted by Dr. Burrows.—(*London Med. Repos.*, vol. iii., p. 443.) The above particulars serve also to weaken the notion of putrefaction.]

That many of the animals which prove thus noxious have derived their mischievous quality from some poisonous mineral, vegetable, or animalcule on which they have fed, seems probable from the well-known fact that many of the most harmless and easily digestible species, if eaten without being disentrained, grievously disorder the stomach, and occasion many of the symptoms above noticed; while even the baracuta, which is ordinarily one of the most deleterious in its effects when eaten whole, becomes bland and innocuous to most persons when thoroughly cleaned, gutted, and salted. There is also, in many cases of the disorder hereby

* The American journals mention many facts of this kind. Dr. Mease, of Philadelphia (New-York Med. Repos., vol. i., p. 161), has recorded several cases demonstrating the serious consequences arising from the poisonous quality of pheasants, (*tetrao cupido*, Lin.) Dr. Barton (*Trans. of the Am. Phil. Society*, vol. v.) has stated cases of the poisonous effects of honey; and two cases of a similar character may be seen in Hosack's Medical Essays, vol. ii.—D.

produced, a strong metallic and especially a coppery taste in the offending substance when rejected into the mouth, and which continues to affect the fauces for a long time afterward,—[though, as is above related, no copper can be detected in poisonous muscles.] M. Orfila has accurately noticed this last symptom in several of the cases he has enumerated; and especially in an example of this disorder originating in a mixed company of whites and blacks who had fed on the conger-eel, in the island of Grenada, in April, 1791. “The negroes,” says he, “suffered more than the whites; they all experienced a coppery taste in the mouth, and a sensation in the œsophagus, as if it were excoriated.”—(*Traité sur les Poisons*, &c., tom. ii., sect. 1006.)

It is in vain to urge that what is thus poisonous to man, must have been at least as noxious to the animals that fed upon it; for poison is a relative term, and it is highly probable that there is scarcely a vegetable or mineral substance but may be eaten, I do not say harmlessly, but even as a safe and nutritious food, by animals of some kind, however destructive to others. The land-crab is well known to feed on the manchineel tree (*hippomane mancinella*); the loxia or gross-beak of the Bahamas on the fruit of the *amyris torifera*, or poison-ash; partridges on the leaves, and bees on the flowers of the *kalmia latifolia*, which are death to sheep, to horned cattle, and to man. So the *cicuta virosa*, or long-leaved water-hemlock, the most virulent plant that grows spontaneously in England, though fortunately not very common to our pastures, is fatal to cows, the most voracious and horses eat it with impunity, and goats devour it with greediness; a fact well known nearly two thousand years ago to the first naturalist of ancient Rome, and thus fully described in his poem, *De Rerum Naturâ*.—(Lib. v. 897.)

—“*Videre licet pinguescere sæpe CICUTA
Barbigeras pecudes, homini quæ est acre venenum.*”

On the contrary, while horses feed with avidity and thrive to fatness on the *agrestis arundinacea*, or reed bent-grass, Linnæus, as he tells us in his *Travels in Shânè*, found a number of goats perishing in an island in which this was the chief herbage.

This interesting subject is pursued with great spirit and high advantage to the most important purposes of practical husbandry, in several articles published in the Swedish *Amœnitates Academicæ*; which give us tables of the best and most agreeable foods for cattle and other domestic animals, deduced from an exercise of that wonderful instinctive power of selection which enables them to discern and to crop those that are a nutritious food for their own species, and to reject the rest. By one of these tables it appears that, of four hundred and ninety-four species of indigenous plants of Sweden, three fourths of them common to our own country, which were offered to horned cattle, two hundred and seventy-six were eaten, and the rest refused; that goats, out of four hundred and forty-nine species, rejected a hundred and

twenty-six; sheep, of three hundred and eighty-seven, would not touch a hundred and forty-one; horses turned away from two hundred and twelve out of two hundred and sixty-two; and swine, out of two hundred and forty-three, made choice of only seventy-two.—(Vol. ii., art. 25. *Pan Suevicus. Resp. N. L. Hesselgren*, 1749.) In another volume of the same interesting work, we have a like series of experiments on a great diversity of insects and worms, with a view of ascertaining how many of them are devoured or rejected by our common poultry (vol. viii., art. 163. *Æsca avium domesticarum. Resp. P. Holmberger*, 1774); to which, however, I can only refer, and must leave the reader to consult it at his leisure.

It is hence perfectly clear that no argument against the existence of esculents in the interior of animals, deleterious to the health of man, can be drawn from the position that such esculents must also prove noxious to the animals that feed on them.

It is at the same time well known that a considerable change takes place in the taste and nutritive qualities of many species of fishes, at various seasons and periods of life, by which they are divested of their nutritive power, and are rendered far less easily digestible; and which consequently lays a foundation for various affections of the stomach. This is particularly the case with the more luscious or oily kinds; as the herring, mackerel, eel, and salmon, all of which are unwholesome, if not pernicious, when out of season. We may also reasonably conclude that climate has a considerable influence upon them, since the most pernicious species are those that exist in the inter-tropical seas.

It is, however, equally certain, that the disorder before us is, in many instances, rather dependant upon idiosyncrasy, or a peculiar condition of the stomach at the time, than upon any quality essentially noxious in the fish itself; for out of twelve or more persons dining together from the same diet, we often find only a single individual affected with the disease before us, while all the rest not only escape, but have made a nutritious and a healthy meal. Even in the same family we occasionally meet with almost as many distinct idiosyncrasies in this respect as there are individuals. Of three sisters, M. Orfila tells us that one was incapable of eating muscles, at any time, without great disorder of the system at large, as well as of the stomach; that the second experienced a like effect from herrings; and the third, from feeding on strawberries. And hence many pathologists have been induced to ascribe every case of colic, from the variety of surfeit before us, to idiosyncrasy alone. But the frequent examples we meet with of the affection extending through every individual of a large party that has fed on the same food, forbid us to limit our ascription of the disease to this single cause. [The symptoms caused by poisonous muscles are carefully detailed by Dr. Combe. In general an hour or two elapses before any ill consequences are felt; and then the bad effects consist rather

in uneasy feelings and debility, than in any complaint about the stomach. In two or three hours, however, a slight tension of the epigastrium is complained of. Cardialgy, nausea, and vomiting occasionally take place, but not generally, nor for any considerable time. A prickly feeling in the hands; heat and constriction of the mouth and fauces; some difficulty of speaking and swallowing; numbness about the mouth, gradually extending to the arms; and great debility of the lower limbs,—are the ordinary symptoms. Some patients have a bad or coppery taste in the mouth. In the abdomen a slight pain is experienced, which is increased by pressure, particularly in the region of the bladder, the functions of which are variously disturbed. In some patients the secretion of urine is suspended; in others it is free, but passed with pain and effort. The action of the heart is feeble; the breathing unaffected; the countenance pale and anxious; the skin cold; the mental faculties unimpaired.—(Dr. Combe, in *Edin. Med. and Surg. Journ.*, No. 94, p. 89.)]

The principles of cure are of easier comprehension than the etiology. The peccant matter must first be discharged from the stomach by an emetic of rapid action, as about half a scruple of white vitriol; shortly after which the lower belly should be stimulated to a like discharge, so that as little of the material as possible that disagrees with the digestive organs may remain in them. The history of the symptoms shows us that the living power is rapidly, prodigiously, and sometimes alarmingly exhausted; whence indeed, in many cases, the tremors, sense of suffocation, faintness, sinking of the pulse, and general depression of strength; as also the swellings that take place through every organ where the cellular substance exists in considerable abundance. It is hence highly important to rouse the system with all speed, by means of the most diffusible stimulants, and warmest cordials and tonics, which may be commenced as soon as the stomach has been evacuated; the most useful of which are sulphuric ether, nitrous ether, ammonia, capsicum, and vinegar diluted with water, sweetened and drunk in abundance. The acids obtained by fermentation answer better in this case than any others, because they possess more of an alcoholic principle. And it is truly striking to notice the almost miraculous power which is sometimes exhibited by this cordial plan of attack. Upon the administration of a single strong dose of ether, the patient, apparently in the act of expiring, has in various cases felt all his symptoms vanish in a very few minutes as by enchantment (*Orfila*, tom. iv., sect. 1008; *Dulong, Gazette de Santé*, Oct. 1, 1812); the pains have ceased; the absorbents, and indeed every other set of organs, recovered their wonted energy; the general intumescence has subsided, and the nettle or other rash disappeared. If, however, the system have been shaken more deeply, and the symptoms do not yield with much readiness, the tonic plan must be persevered in for many days or even weeks.

The THIRD VARIETY is usually produced by

pernicious vegetables, instead of animals, that have been taken for food, or along with food; or esculent vegetables that disagree with the stomach, as in the preceding variety, from a morbid state of this organ, or from a peculiarity of constitution. I have already observed that the symptoms in this modification of the disease evince great nervous irritation with a rapid exhaustion of the sensibility. There is severe spasmodic pain in the intestinal canal, with cramp, spasms, or convulsions, extending over the system more or less generally, accompanied with or succeeded by a lethargic drowsiness, from which it is often difficult to rouse the patient; and from which, also, when roused, he instantly relapses into convulsive agitations; evidently proving that an acrid and a narcotic principle are combined in the unsuspected cause. This cause is usually mushrooms, or rather deleterious fungi that have been mistaken for the genuine edible mushroom, or *agaricus esculentus*. The agaric is so extensive a genus, and many of its species, to an unpractised eye, have so near a resemblance to each other, that it cannot be wondered at that such a mistake has been committed: though perhaps the plants that, through such an error, have been most frequently gathered, are the bulbous agaric, the Medusa's head, the raven's eye, the hemlock mushroom, and the *agaricus muscarius*. It is possible, indeed, that even the genuine mushroom itself may prove deleterious to some idiosyncrasies, or to some stomachs in a morbid state of constitution; but then the mischief is in almost every instance confined to an individual alone, the rest of the company eating of the same dish with satisfaction and pleasure.

As there is no critical mark to determine at once between poisonous and salutary mushrooms, we may lay it down as a general rule, that those should be suspected and avoided that grow in moist and marshy grounds, and especially in the shade; that have a dirty-looking surface, and whose gills are soft, moist, and porous. For the most part the smell of these is virulent, and they are covered with a calyptra or veil.

There are, however, a considerable number of other vegetables that produce a like effect when taken by accident for food, or along with food; as the *cicuta virosa*, or water-hemlock, the leaves of which have been mistaken for smallage, and the tap-roots for parsnips; the *athusa cynapium*, or fool's parsley, which has been culled for common parsley; and the *secale cornutum*, or spurred rye. The last is productive of very serious evils in different forms, and we shall hence have occasion to return to it when describing erythematic pestis, and mildew-mortification, both which also result from its use. Rye becomes spurred or horned in the shape of its ear, apparently from having numerous punctures made by different insects in the fresh pullulating grains of the glume, as a nidus for their minute eggs, in the same manner as the nut-weevil (*curculio nucis*) pierces the young and tender nut of the hazel for the same purpose. And as the effects produced by the

grain thus diseased are very different in different seasons or climates, we have reason to believe, that its juices are themselves rendered noxious in a different manner, according to the species of insect that makes the attack. It is also said that the common garden rue (*ruta graveolens*), when eaten to excess, is succeeded by the same symptoms of ventricular pains, spasmodic action, and coma, though in a less degree; but I have never seen such consequences, and have reason to think that they have been overrated.

Most of these symptoms are also produced by feeding on soups, or other dishes, that have been cooked in copper vessels containing verdigris. We have the same violent gripings and muscular commotions, excited by the acid quality of the plant just noticed, and in almost all instances headache and confusion of intellect, and sometimes coma. In all these cases, however, we can easily detect the nature of the poison, by the intolerable coppery taste of the mouth, and the green or greenish-yellow colour of the matter rejected from the stomach.

The cure, as in the preceding variety, must be promoted by evacuating, in the first instance, the poisonous principle, as largely as possible, from the stomach. Where the local irritation is great, demulcent mucilages should succeed; or soap where the effect has been produced by salts of copper. After which, if there be much general convulsion or other irritation of the nervous system, it must be allayed by opiates.

SPECIES IV.

COLICA FLATULENTA.

WIND-COLIC.

PAIN ACUTE, EXTENDING TO THE PIT OF THE STOMACH, OFTEN IMPEDING RESPIRATION; ACCOMPANIED WITH GREAT FULNESS AND FLATULENCE; AND RELIEVED BY PRESSURE, BENDING THE BODY FORWARD, OR EXPULSION OF WIND.

This species is produced by crude and flatulent fruits, and whatever lowers the tone of the alimentary canal; as too long fasting, fear, or grief, and all the causes of dyspepsy, with which it is often complicated, and to which the reader may turn. Like dyspepsy, indeed, it seems to depend upon local debility, whose seat is in the small intestines, and consequently in the direct neighbourhood of the stomach. It is often accompanied with great costiveness, from the spasmodic action, which runs in a larger or less degree through the whole of the intestinal canal, and considerably adds to the torture, and increases the tumefaction and tenseness of the abdomen; which are sometimes so extensive as to resemble *emphysema abdominis*, or tympany.

The last symptom is peculiarly striking and oppressive in persons of an hysterical diathesis, who are attacked with this complaint from very slight causes; and in whom it is often combined with syncope or clonic spasms of various kinds.

In attending to the means of cure, we may here proceed at once with some degree of bold-

ness; since, notwithstanding the violence of the pain, it is not often that inflammation is to be apprehended, at least in the commencement of the disease: and hence the warmest carminatives, and even alcohol, may be had recourse to; for whatever will carry off the flatulence, will carry off the pain and costiveness. Hence a spoonful of brandy, or, which is better, a dose of tincture of rhubarb, ammonia, infusions of herbs containing essential oils, as mint, peppermint, pennyroyal, are generally consoling and salutary. For the same reason, the aromatic spices may be had recourse to with success, and particularly in connexion with opiates. Of the spices, the nutmeg, on account of its greater volatility than most others, and especially on account of its established reputation for producing quietism and even sleep, has a peculiar claim to attention.

The only disadvantage of opium is, that it has a tendency to diminish the intestinal, and indeed all the secretions, excepting that of sweat: and, on this account, it has been objected to by many physicians; but, from its power of allaying spasmodic irritation, and consequently of producing ease, it becomes of so much importance, that it ought unquestionably to be called into use: and there are cases in which, from this very power alone, it may indirectly act the part of an aperient. The opiate confection, as combining an aromatic with a narcotic principle, is a highly valuable as well as an elegant preparation. And after the pain has subsided, an active purgative, according to the course recommended by Dr. Cullen (*Mat. Med.*, vol. ii., p. 249), may be administered.

Opium may also be given in the form of an injection, which should not exceed five or six ounces, for otherwise it will probably be thrown back. It will be often of great use to unite with the narcotic a pretty free dose of turpentine, or some of the warmer balsams, especially that of copayva; and to apply rubefacients to the epigastric region.

The convalescent treatment may be the same as already recommended under dyspepsy.

SPECIES V.

COLICA CONSTIPATA.

CONSTIPATIVE COLIC.

THE GRIPING PAIN SEVERE; THE COSTIVENESS OBSTINATE; GREAT TENSION, WITH LITTLE FLATULENCE: THE VOMITING SOMETIMES ACCOMPANIED WITH FECES; THE COSTIVENESS WITH BLOODY STRAININGS; TERMINATING, WHERE NOT FATAL, IN A FREE DEJECTION OF THE INFARCTED MATTER.

The pain is here produced by indurated meconium, or feces, or other intestinal concretions, and especially those which are known by the name of bezoards, and will be hereafter described under the genus *ENTEROLITHUS*: and we hence obtain the following varieties:—

a Meconialis.

From viscid meconium.

Colic of newborn infants.

- β Fæcosa. From indurated feces.
 Stercoraceous colic.
 γ Enterolithica. From bezoards, and
 Stony colic. other intestinal con-
 cretions.

The first two of these varieties are the result of a superabundant action of the intestinal absorbents, or of a deficiency in the peristaltic power of the intestinal tube; in consequence of which, from the length of time the confined materials occupy in completing their descent, the meconium in infants becomes so viscid as not to be urged downwards, and remains in the intestines till it grows acid; and the feces of later life, exhausted of moisture, hardened into one solid mass, possessing the figure of the intestine, or, separating into smaller pieces, appear, when discharged, in the shape of balls or buttons, often as hard as sun-burnt clay, and have been called, though not quite accurately, scybala; yet sometimes they make a near approach to this substance, and consist of masses of indurated feces, combined with a certain portion of mucus or oleaginous matter secreted into the intestines, and producing a cetaceous or soapy feel.

Of the stony variety, the following is an extraordinary example related by Dr. König of Berne.—(*Phil. Trans.*, year 1686.) A young woman of twenty-five years of age, by name Margaret Lawer, after an anomalous and general disorder, discharged continually the contents of the intestines, and even the clysters that were injected, by the mouth, and at length a number of stones as hard as flint, some in fragments, some of the size of peas, others of that of filberts. A clashing of stones against each other was felt by pressing the hand upon the abdomen: there was great constipation, severe gripings, and dysury; and the urine, when voided, was often loaded with a gravelly matter. The aliment and injections being constantly returned by the mouth, Dr. König desisted for four months from offering her either meat, drink, or medicine of any kind, excepting occasionally a spoonful of oil of almonds. Blood was now and then vomited, from the violence of the spasmodic affection of the stomach; and frequently urine to the amount of three or four ounces at a time, of a strong taste and smell. The disease seems to have lasted, with remissions, from January, 1681, to February, 1683, at which period the history is abruptly dropped, though the patient seems to have been in a state of recovery. It was preceded by the appearance of vesicular eruptions on the skin. The chymical examination of the calculi is loose and unsatisfactory.

The oleaginous purgatives, soap injections, and mucilaginous diluents, to diminish the irritation of the intestinal absorbents, will here be found most successful. Small doses of neutral salts, sulphur, and acidulated drinks, may also be of service in promoting the latter intention. If the griping be severe, and the case urgent, terebinthinate injections, in the last two varieties, will also be highly expedient, and not unfrequently produce speedy relief. In these cases the injections should be copious, so that the fluid may readily insinuate itself between

the imprisoned matter and the coats of the intestines: and the turpentine should not be less than from half an ounce to an ounce, diligently triturated with yolk of egg, so as to be perfectly diffused and suspended in the menstruum. "Thus prepared, we have found it," says Dr. Cullen, "to be one of the most certain laxatives that can be employed in colics and other cases of obstinate costiveness."*

SPECIES VI.

COLICA CONSTRICTA.

CONSTRUCTIVE COLIC.

A SENSE OF STRICTURE IN SOME PART OF THE INTESTINAL CANAL; OFTEN OF FLATULENCE, GRADUALLY PASSING OFF BY THE STRICTURE; THE BOWELS TARDY; DISCHARGING WITH DIFFICULTY SMALL LIQUID STOOLS.

This species bears a near approach to *proctica callosa*, or the callous contraction of the rectum; which last, however, as accompanied with less griping and flatulence, and consequently having less of the character of colic, and more particularly from its being in most cases within the reach of manual examination and surgical aid, and capable of assistance by a different mode of treatment, is entitled to a distinct consideration.

[Stricture of the intestines, in the early stage of the disease, gives rise to colic pains and costiveness, alternating with bilious diarrhoea. After some time, solid feces are very rarely passed, and only after a great effort; and they are of an extremely slender calibre.]

The proximate cause of the disease before us is a permanent stricture existing in some part of the intestinal canal beyond the reach of the finger, from callosity, scirrhusity, a ring of tubercles or caruncles, or whatever else has a tendency to thicken its coats and diminish its diameter. [Strictures are more frequently met with in the colon and rectum, than in the small intestines: and Dr. Monro has seen the natural diameter of the colon so much reduced, that an ordinary quill would hardly pass the constriction. When the stricture is great, the bowel is generally enlarged above it (*Baillie's Works*, by Wardrop, vol. ii., p. 158), and even ulcerated. Sometimes, indeed, it gives way; its contents are effused; and the patient, after labouring under colic for a few hours, is suddenly seized with very acute pain in the abdomen, rapidly followed by a sud-

* *Mat. Med.*, vol. ii., p. 181. Every man of experience is aware, that when a person takes chalk mixture, or magnesia, in considerable quantities, intestinal concretions are liable to be formed, unless the bowels be well cleared out occasionally with a brisk purgative. The carbonate of iron will sometimes accumulate in the bowels in large masses, creating obstruction. Dr. Elliotson has known collections of it take place in the rectum. He had a patient labouring under tetanus, to whom he gave this remedy with success; but, when purgatives were not given, there was pain in the rectum, and it was necessary to pick the iron out of it: a shovelful was found in his bed.—(*See Med. Gazette for 1832-3*, p. 598.)—Ed.

den sinking of the pulse, cold sweats, and death.—(*Morbid Anatomy of the Human Gullet*, &c., p. 301, 302.) When scirrhus affects the bowels, the diseased portion of them is always rendered narrower, and sometimes nearly imperious. According to Meckel, the disease begins in the peritoneal coat and glandulæ muciparæ, whence it afterward extends to the muscular and villous coats. The effect of it is to confound together all the tunics, to thicken and harden them, and, in the end, to produce cancerous ulceration.—(*Bourdon, Revue Méd.*, Mai, 1824, and *Meckel's Anat.*, vol. iii., p. 296.) The muscular coat is also subdivided by membranous septa, and the internal one sometimes projects in the form of hard irregular folds. In persons of advanced age, scirrhus of the large intestines is not uncommon, and it mostly attacks the sigmoid flexure of the colon or the rectum. The reason of this fact is referred by Dr. Baillie partly to the villous coat of the lower end of the great intestines containing many glands, and partly to the sigmoid flexure of the colon being naturally its narrowest part, and most liable to be irritated by the passage of hard substances. But though strictures are most frequent in the colon and rectum, they are sometimes met with in the small intestines. In the Museum of the University of Edinburgh is a specimen of a stricture, extending seven inches along the ileum.—(*Monro*, op. cit., p. 301.)

Besides the foregoing scirrhus disease, by which the intestinal tube may be obstructed, there are other morbid alterations by which the same consequence may be produced. One is an elevation of the mucous membrane into thickened folds by an accumulation of the cellular membrane.—(*Baillie's Works*, vol. ii., p. 159.) Another is a thickening of the mucous or villous coat alone, coagulable lymph being effused upon it. In the collection of Mr. A. Burns is a specimen taken from a child, where a gelatinous substance, mixed with coagulable lymph, adhered very intimately to the villous coat of the sigmoid flexure of the colon and the rectum; and above the sigmoid flexure, the intestine had given way. In some instances the intestine is completely filled with coagulable lymph, which may either be voided by stool, or remain and prove the cause of death.—(*Monro's Morbid Anatomy*, &c., p. 119–122.) The intestinal canal, and particularly the colon and rectum, are sometimes the seat of polypi, or of various other excrescences, some of which are hard and solid; others spongy, loose, and soft. One is termed miltrike by Professor Monro, and has a very fetid smell: Meckel (*Anat.*, vol. iii., p. 297) expresses a conviction that the disease here alluded to is in reality fungus hæmatodes: but such a case is rare, and has never been seen by Mr. Wardrop.—(*Baillie's Works*, vol. ii., p. 161.)]

The colon and rectum, highly sensible in a state of health, are peculiarly irritable from the diseased action, and the specific symptoms are the consequence of irritation produced by the mechanical pressure of the feces; and often by acrimony from the retention. In most cases the stricture lies beyond the reach of topical ap-

plications. Purgatives afford but temporary relief.—(*Monro's Morb. Anat. of the Human Gullet*, &c., p. 302.) Of late the conium has been chiefly trusted to, in conjunction with the mercurial pill. But I am not aware that these have proved decidedly advantageous. The spasmodic attacks must be encountered by the remedies already recommended in spasmodic and flatulent colic: and the habitual uneasiness felt in the intervals, will be best alleviated by a rigid attention to a light, liquid, and aperient diet. Unfrequent as this disease is in general practice, I happen to have at this time two patients labouring under it: one a lady of about thirty-five years of age, who has been subject to it for ten years, and is incapable of passing feces more voluminous than those of an infant; and the other a man, forty-nine years old, who has laboured under the disease for twenty-one years, and can never pass a motion larger than a crow-quill. Yet, by strict attention to diet, both are able to exist, with only occasional inconvenience and pain; the last married about two years since, and his wife has lately brought him twins. He lives upon liquids altogether.

[As the sigmoid flexure of the colon, near its termination in the rectum (*Penkivil*, in *Edin. Med. and Surg. Journal*, No. 72), is frequently the seat of the disease, this part should be carefully examined in every case of total obstruction of the bowels, not arising from hernia. It is requisite for the purpose, says Dr. Willan, to employ a bougie thirteen inches long, and of a proportionate strength. He adds, "I lately saw a lady thus relieved, who had been twenty-six days without any evacuation from the bowels, and who seemed nearly exhausted by violence of pain and distention of the abdomen, hiccough, cold-sweat, &c. It is remarkable how long patients subsist under these distressing circumstances. In one instance, the time was twenty-nine days; in another, thirty-three days. As the latter patient recovered, after enduring every torture such a disorder could inflict, practitioners may be encouraged to persevere steadily in their attentions."—(*Willan on Diseases in London*, p. 185.) When this species of colic depends upon the presence of a polypus, or other excrescence in the intestinal canal, beyond the reach of surgical means, the palliation of symptoms is all that can be attempted. The true nature of such cases is scarcely ever ascertained till after death.

GENUS VII. COPROSTASIS. COSTIVENESS.

OBSTINATE RETENTION OF THE FECES IN THE INTESTINES.

THE generic character is expressed in the generic name, which is a compound term, importing emansion or retention of feces—*κοπροστασις*, from *κοπρος* and *ιστημι*, whence the well-known and opposite terms *copragoga* and *eccoprotica*, to express purgatives, or such medicines as quicken the passage of the feces.

Whether mere tardiness of evacuation should always be regarded as a disease, may be ques-

tionable: some persons are accustomed to have their bowels moved not oftener than twice a week; and to such a week's costiveness is attended with no inconvenience. [The proximate cause of constipation may consist in an unusual slowness of the peristaltic motion of the bowels, or in an obstruction to the passage of the feces, while the proper peristaltic motion continues. The natural action of the bowels is considerably different in individuals of different constitutions, and even in the same individuals at different periods; so that it is not easy to say when the peristaltic motion can be considered as preternaturally slow, while the general health remains good. But it is probable that in most habits a stool should occur once in twenty-four hours, although many persons retain their feces much longer without inconvenience. Dr. Cullen believed that every deviation from a diurnal stool is an approach to an unnatural state.] Rhodius gives a case of feces retained nearly a month (Cent. ii., Obs. 61); and Panarolus one of three months' retention without mischief.—(*Jatralog. Pentecost.* i., Obs. 1.) Chaptal relates the history of a female, who for four months had no discharge either from the bowels or the kidneys, and as little evacuation by sweat, notwithstanding that her diet was confined to milk-whey and broths. She was at length cured by using the coldbath for eight days successively. When but a very small quantity of food is taken habitually, the egesta bear a like proportion, are small in amount, and usually slender in volume. This is particularly the case with those who are enabled to endure long periods of fasting, as we have already had occasion to observe under *Limosis exerts protracta*: and hence the collectors of medical curiosities have furnished us with various examples of feces retained for half a year (*Samml.* Cent. i., obs. 24; ii., 65, 98; iii., 26, 45), two years (*Samml. Medic. Wahrnehmungen*, band iv., p. 294), and in one or two instances not less than seven years (*N. Samml. Med. Wahrnehm.*, band i., p. 423), without serious mischief.

In all such cases, the feces are discharged in indurated and minute balls, something like sheep's dung. But it does not always happen that those who labour under this affection eat sparingly. Professor Thomassini of Parma, in 1808, attended a man, thirty years of age, who laboured under an habitual costiveness of this kind, though his appetite was good, and he was accustomed to eat twice as much as other men. He had been costive from his youth, but the torpor of his bowels had increased yearly. From his twentieth to his twenty-fourth year, he had only one evacuation every eight or ten days, which interval was afterward increased to twelve. At thirty, when M. Thomassini saw him, the intervals were extended to twenty-two days. No regimen, nor medicinal process, had produced any benefit. Purgatives, indeed, operated, but occasioned such debility that they could not be persisted in. The heat was natural, but the pulse frequent.—(*Diet. des. Sc. Méd.*, art. *CAS RARES.*)

[A remarkable case was published by Dr. Crampton. The patient, a female, in her thirty-seventh year, had had no evacuation from her bowels for eight months, and only two or three motions in the year preceding that in which the particulars were drawn up. She also passed scarcely any urine, and this with pain. Her usual sustenance was tea, toast, milk, and gruel. The abdomen was free from fulness or swelling. In the intervals of meals, she often voided from the stomach matter of stercoraceous quality, and sometimes of a urinary smell.—(See *Dublin Hosp. Reports*, vol. iv., p. 305, &c.) The same physician refers also to another similar example which was under his care, and in which a stool was considered quite an extraordinary occurrence. After death, the colon was found immensely distended, nearly impervious at its lower part, and the bladder diseased. In the first of these two cases, a stricture of the colon was likewise suspected.] “Dr. Heberden knew a person who, all his life, had but one motion a month: he must have had a great deal to carry about with him; and then, as a contrast, the same physician mentions another individual, who had twelve motions a day for thirty years: that must have been equally troublesome—it was perpetual motion.”—(*Medical Gazette* for 1832-3, p. 661.—*ED.*)

Costiveness is not necessarily connected with colic, flatulence, or any severe pains; though, as already observed, under particular circumstances, it may become a cause of all these. In its simple and constitutional form, it is generally rather a troublesome than a violent or dangerous complaint. But this is not invariably the case: and a constipated state of the bowels, whether idiopathic, or the concomitant of other diseases, is frequently highly injurious to the constitution; producing, when it is idiopathic, a variety of disorders; and aggravating, when symptomatic, the diseases of which it is a symptom. Costiveness may proceed from two very distinct sources; and as each of these possesses symptoms of its own, and is considerably discrepant from the other, we are enabled with ease to contemplate the genus under the two following species:—

1. Coprostasis	Constipata.	Constipation.
	Obstipata.	Obstipation.

SPECIES I.

COPROSTASIS CONSTIPATA.

CONSTIPATION.

THE FECES WHEN DISCHARGED CONGESTIVE AND VOLUMINOUS; THE TEMPERAMENT FIRM AND RIGID.

In persons of a compact and robust habit, with hearty appetite and strong digestive powers, the intestinal absorbents occasionally evince an excess of action; and the feces, while they become hardened in consequence of such action, assume, from their copiousness, the figure and volume of the large intestines through which they pass.

The increased action of the absorbents, which

is the common proximate cause of the present species, may be produced by violent exercise, which heats the blood and throws off an excess of fluid in the form of perspiration from the surface; or by too stimulant a diet, particularly of rough port wine. [Travelling in a carriage, or on the water, is said to have greater effect in bringing on costiveness than more considerable bodily activity. The editor is inclined to believe, that it is rather the confinement, and the want of usual exercise, which should here be regarded as the cause of costiveness; and that the complaint may be imputed, with more probability, to a defective state of the biliary and other abdominal secretions, and to inefficient peristaltic motion, than to an increased action of the intestinal absorbents. Dr. Cullen (*Mat. Med.*, vol. ii., p. 496) ascribed costiveness in such cases to the abstraction of the intestinal fluids, secreted from the mucous glands and exhalant arteries. With respect to horse-exercise, the editor suspects that the accounts of its producing costiveness are founded on a mistake, and that it generally promotes regularity in the functions of the bowels, provided its beneficial operation be not counteracted by intemperance. Many persons who are in the habit of riding, are also in the habit of drinking port, brandy and water, and other astringent heating beverages; and if they suffer from costiveness, the exercise on horseback bears the blame that ought to be laid upon their diet.]

Costiveness may be the result of too astringent a diet; as where bread, for instance, is adulterated with a considerable quantity of alum: for the mouths of the secretory vessels of the intestines, which should pour forth a large portion of fluid, become hereby contracted, and secrete but a small proportion. Astringents, also, by giving some degree of rigidity to the muscular fibres of the intestines, retard the peristaltic action, and thus become a second cause of constipation.

As the feces are forced forward by the peristaltic action of the intestines, it is obvious that, whenever this action is weakened, there must necessarily be a retardation, and consequently an accumulation of the feces. This sluggishness or torpidity of the bowels is produced by various causes; for sometimes the food is too insipid and destitute of stimulants, and sometimes there is a deficiency in the secretion of bile, which appears to be a natural stimulus to the internal surface of the intestines; and we have reason to believe, that the latter is sometimes secreted with its qualities imperfect; and sometimes, also, the muscular fibres of the larger intestines lose a considerable degree of healthy irritability, and are reduced to an extreme of paresis that amounts almost to paralysis. And, if this occur, as it does occasionally, without much failure of the appetite, the accumulation of feces will be in some instances prodigious. In the case of a young woman aged twenty-eight, the distention of the abdomen from this cause was so general as to be mistaken for pregnancy, especially as there was occasional sickness, with menstrual sup-

pression, and a sympathetic enlargement of the breasts. The disease terminated fatally in about three years from its commencement. The colon, which was among the late Mr. Taunton's preparations, he was so obliging as to show me: it measured in circumference more than twenty inches, and on dissection was found to contain three gallons of feces.

[The causes which may obstruct the passage of the feces, without any deficiency of peristaltic action, occur either in the intestines themselves, or the neighbouring parts. In the intestines, a mechanical impediment is sometimes occasioned by a thickening of the coats, which straitens the passage, or by scirrhous tumours, especially near the lower extremity of the canal. Sometimes the cavity is partly filled by calculous concretions. The costiveness attending enteritis has also been referred to a lessening of the calibre of the bowels by spasm; but no doubt now exists that it is rather owing to an interruption of the secretions naturally poured into the intestines, and to a diminution in the action of their muscular fibres; for, as Bichat fully ascertained, it is not the character of an inflamed muscle to contract even with its ordinary vigour. Tumours in the neighbouring parts, compressing the intestines, necessarily impede the passage of the contained feces. Hence, in pregnancy, costiveness is a common consequence of the pressure of the enlarged uterus on the great intestines; and a seatomatous tumour in the omentum has been known to produce the same effect.]

A stricture in any part of the large intestines, from whatever cause, has a tendency to produce an accumulation of feces, in the same manner as it produces one species of colic. But colic does not always follow; for the bowels are less irritable than usual, and the stomach continues sound. Strictures in the colon have sometimes existed without being suspected. Dr. Baillie has given a striking example in a case related to him by Sir Everard Home, but a still more striking one from his own practice.* In the last, the patient, a shoemaker, aged thirty, subject to habitual costiveness, became at length much more so; and, from having motions three or four times a week, passed them not oftener than once or twice in a week or a fortnight, and this, moreover, with considerable pain in the lower part of the belly; and at length was incapable of passing a motion by any means. The real cause of the disease not being very clearly suspected, the strongest purgatives were given to him, both by the mouth, and in the form of clysters, as five grains of calomel and ten of gamboge; ten grains of calomel and thirty of jalap; and at one time four grains of elaterium, which made him sick, but produced no other effect. Two drachms of gamboge were given in the form of an injection, and afterward tobacco-smoke, but altogether in vain; as were also draughts of

* Trans. of a Society for Med. and Chir. Improvement. See also a case, very similar in every particular, reported by Mr. Sterry, in the London Med. Repository for May, 1823.

crude quicksilver by the mouth, shocks of electricity through the abdomen, and the affusion of cold water on the feet. His appetite was but little interfered with, and he passed water freely. A scoop was introduced into the rectum, but this gut was found empty. Under this state of things the belly swelled gradually, and at length arrived at an enormous size, and the patient died in the fifteenth week from the last evacuation. An examination after death showed the real nature of the cause; for at the lower end of the sigmoid flexure of the colon there was a narrow stricture, which would hardly admit the passage of a goosequill, accompanied with an ulcer, which was partly in the situation of the stricture, and partly in the gut above it. This intestine was peculiarly loaded with feces, and enormously distended; the mean of the transverse diameter being above six inches. All the large intestines, where the distention was considerable, had their muscular coat a good deal strengthened, and the longitudinal bands had become twice as broad and thick as in their natural state; the system thus wonderfully accommodating itself, for many weeks, to circumstances which seemed incompatible with the continuance of life. [This case demonstrates the value of the advice given by Willan, respecting the use of a long bougie, as mentioned in the observations on colica constricta.]

The effects of constipation, when long continued, are, pains in the head, nausea and sickness at the stomach, febrile irritation, general uneasiness in the abdominal region, congestion in the abdominal organs; and hence an impeded circulation of the blood, piles, varices in the lower limbs, and, as we have already seen, colic. [Many hysterical affections, chlorosis, and chorca, or St. Vitus's dance, formerly supposed to be unconnected with the state of the bowels, are now proved to be very prejudicially influenced, if not excited by constipation. Even symptoms bad enough to cause the case to be set down as phthisis, and the patient to be sent to Madeira, were ascertained by Dr. Borthwick to arise from habitual costiveness, and to yield to purgatives.]—(*Edin. Med. Journal*, No. 82, p. 69.)

The best aperients, in the present species of costiveness, are those which quicken the descent of the feces with as little increased action as possible; as diluent drinks sweetened with manna, sugar, or honey; the expressed oils of mild vegetables, as the pistachio, olive, and almond; the oleaginous farina of the cocoanut in the common form of chocolate; figs, tamarinds, the pulp of cassia alone, or in the compound of lenitive electuary; neutral salts. Dr. Arbuthnot advised the use of butter, marrow, and fat. Dr. Cullen found four ounces of fresh butter, taken in the morning, produce a stool or two more than usual in the day. Nauseating doses of calomel and ipecacuanha, or of calomel and antimonial powder, will also frequently be of use; and the patient should habituate himself to evacuating the bowels at a certain hour of the day, and should even accustom himself to an effort to this effect,

though he may not always be successful. And where this milder process fails, the more powerful purgatives must be had recourse to.

In some instances of very great difficulty, and of an anomalous kind, an affusion of cold water has been accompanied with great success after all common cathartics, quicksilver in its metallic state, antimonials of various kinds, and injections of every sort have been tried in vain. Two striking examples of this occur in a letter from Dr. Spence of Guildford to Dr. Reynolds, published in the *Med. Trans.* of the College.

[By Dr. Daniel, charcoal was found an efficacious remedy. The dose was from one to three tablespoonfuls, given in lime-water, or milk, every half hour or hour.—(*Philadelphia Journal*, No. 9, p. 119.) Spirit of turpentine, in the dose of half an ounce, mixed with an equal quantity of oleum ricini, has also succeeded.—(*Edin. Med. Journal*, No. 85, p. 307.)

Instead of adopting the latter plans, the generality of modern practitioners would administer the oil of croton, a very minute dose of which has great power in relieving obstinate constipation, when other cathartics, even in large and repeated doses, have no effect. Mr. Liff has reported fourteen cases, in which its usefulness was most decidedly proved.—(*Lond. Med. Repository*, No. 97.) The average dose for an adult is one, or at the utmost, two drops; and, perhaps, as Mr. Brande observes, the best, or at least the most active form for its exhibition, is that of a pill made up with crumb of bread. It may also be rubbed down with mucilage, and mixed with half an ounce of any aromatic water.—(*Manual of Pharmacy*, p. 183.) However, according to Mr. Pope, the best mode of administering the oil is to dissolve it first in a little alcohol, in the proportion of about one drop to half a drachm, in which state it may be more easily diffused in some simple fluid; and, by acting on an extensive surface, the purgative effect, he says, is more speedily ensured. The alcoholic tincture, recommended by this gentleman, has been given very successfully to children.—(*See Med. Chir. Trans.*, vol. xiii., p. 99.) In numerous instances of difficult deglutition, the simple application of the oil to the tongue has answered the purpose. When the stomach is so irritable as not to bear ordinary cathartic medicines, the oil of croton is also a valuable remedy. It has sometimes been given in clysters, in which form the dose may be five or six drops.* In one very obstinate case, suspected

* The croton-oil is now much used by American practitioners in cases of obstinate constipation. After ordinary depletion by the lancet, which will often prove serviceable, and other general relaxing means, the croton-oil may be given in doses of one or two drops every two or three hours, to a very considerable extent. We have given it to the amount of twelve drops, with no other effect than that of producing a moderate action of the bowels. In a case of this disease which had existed for fourteen days, and had resisted the most approved remedies, Dr. J. W. Francis used the croton-oil to the extent of twenty drops, given in doses of two drops every three hours; the patient was relieved without any of the bad consequences

to depend upon intromission, Dr. Chisholm employed with success a strong solution of common yellow soap, of which more than a large wash-hand basin was gradually but perseveringly thrown into the large intestines with Read's syringe.]*

SPECIES II.
COPROSTASIS OBSTIPATA.
OBSTIPATION.

THE FECES, WHEN DISCHARGED, HARD, SLENDER,
AND OFTEN SCYBALOUS; THE TEMPERAMENT
WEAKLY, OR THE HABIT SEDENTARY.

This is in most cases the result of a sluggishness of the peristaltic motion in persons of infirm or delicate health: in consequence of which, the refuse matter of the aliment, usually small in quantity, is a long time passing through the intestinal tube, and hence becomes indurated, shrunk, and shrivelled, so to speak, by the length of time it is exposed to the power of the intestinal absorbents, notwithstanding they may have no such increased action as occurs in the preceding species. This form of costiveness is most frequent in persons of advanced life; in whom the feces, minute in quantity, and deprived of moisture, are sometimes discharged in the form of a scroll, and sometimes in small lumps, of the shape of buttons or balls, as I have already observed when treating of *colica constipata*; which affection also, as there remarked, is often produced by the irritation that these retarded materials at length excite. So feeble, indeed, is the expulsive power of the intestines in many cases of old age, that it is sometimes necessary, as recommended by Dr.

which are sometimes ascribed to this powerful agent. Dr. Chapman, of Philadelphia, has advised, in formidable cases of this affection, injections of starch or mucilage, containing from four to eight grains of tartar emetic. Dr. Hosack (*Essays*, vol. ii.) has published the details of several cases, which were treated successfully by emetics. From the sixteen which he has witnessed, he concludes:—1st, That in the commencement of constipation, or in its more advanced stage, when the symptoms of inflammation have been subdued by the lancet, emetics may be used with advantage to remove the hepatic obstruction, and to counteract the constriction and pain usually attendant in this disease. 2d, That the good effects occasionally resulting from injections of tobacco-smoke, or from the use of tartarized antimony, administered by injection, may be accounted for by the nausea and vomiting which have been the effects of its operation, but which are to be obtained with more certainty by administering emetics.—D.

* Med. Repository. The particulars of a case of obstinate constipation were lately communicated to the editor, where a practitioner in the country determined to attempt to draw out the contents of the intestines with a syringe; but instead of succeeding, he contrived to force an enormous quantity of air into the bowels, and to make his patient swell like a balloon when receiving gas. In this condition, the patient was left scarcely able to respire. The blunder was obvious to the family, and the doctor dismissed.—Ed.

Vol. I.—I

Warren, to introduce a sort of marrow-spoon up the rectum, for the purpose of bringing away the dry masses that have lodged there.

[When a large accumulation of feces takes place in the rectum or colon, it becomes itself the cause of a most distressing constipation, attended with peculiar symptoms, and sometimes terminating fatally. The disorder was first described by an anonymous writer (*Med. Obs. and Inq.*, vol. iv., p. 123), and additional cases of it have been subsequently reported.—(*Duncan's Med. Comment.*, vol. x., p. 255; vol. xii., p. 282.) It is the more important to attend to this complaint, because it assumes the appearance of a diarrhoea, or rather a chronic dysentery, and has often been erroneously treated with astringents and opiates. The patient complains of severe pain about the lower region of the belly, remitting, and again returning after frequent but short intervals, and accompanied with a bearing down, and almost continual inclination to go to stool. Only a small quantity, however, of thin discharge, perhaps mixed with little hard knobs of excrement, follows, after which the pain abates. When, from a previous costiveness, and the abovementioned symptoms, the loaded state of the rectum is to be suspected, this bowel should be examined *per anum*, and the feces broken down and extracted with some convenient instrument. The accumulation that takes place is sometimes very great. This case is frequent in persons of advanced age, and more frequent in the female than the male sex. Whatever tends to lessen the peristaltic motion of the bowels must induce a predisposition to it; and it has been often occasioned by the long-continued use of bark, opium, and other astringent medicines.]—(*Bateman, in Rees's Cyclopædia*, art. CONSTIPATION.)

It sometimes happens, however, that a contrary temperament prevails in old age; that the bowels are irritable, and the motions loose. Celsus (*Medicin.*, lib. i., c. 3) has laid it down as a maxim, that when the bowels are loose in youth, they commonly become confined in advanced life; and that if confined in youth, in advanced life they are often laxative. Quibus juvenibus fluxit alvus, plerumque in senectute contrahitur; quibus in adolescentia fuit adstricta, sæpe in senectute solvitur. I cannot say that I have been able to confirm this position by my own observation or experience.

In costiveness from this cause, our aperients must be derived from other materials than those recommended under the last species; for here we have far less reason to be afraid of the warmer and aromatic purgatives. And hence, while we allow a freer use of wine, we may successfully have recourse to aloes, the compound pill of this name, and the balsam of copayva.

The analeptic pill of Dr. James, which combines a preparation of antimony with resinous purgatives, is often a very serviceable medicine: as is also the form recommended by Dr. Parr, which consists of half a drachm of the gum-pill, the same quantity of the pilula aloes cum myrrha, with ten grains of antimonial powder, made into fifteen pills.

GENUS VIII.
DIARRHŒA.
LOOSENESS.

THE ALVINE EVACUATIONS CRUDE, LOOSE, AND TOO FREQUENT; WITH LITTLE OR NO GRIPING OR TENESMUS.*

Of all the specific forms of this disease, the chief proximate cause, as it is called, or the symptom that gives rise to all the other symptoms, is an increased peristaltic action throughout the whole or a great part of the intestinal canal: and as this may be produced by various means and under different circumstances, it must often stamp a peculiarity in the character of the disorder, and lay a foundation for numerous species.†

The peristaltic action of the intestines may

* "Pain, or griping, is occasionally an attendant, but not necessarily so."—(Drs. Crampton and Forbes, in *Cyclop. of Pract. Med.*, art. DIARRHŒA.) Professor Elliotson's definition of diarrhœa is, "frequent, liquid, and rather copious feculent stools, not dependant upon debility of the sphincter ani." In dysentery, the stools are not feculent. In diarrhœa, "there is only pain at the time of the evacuation; but in dysentery, the griping is horrid, and is not lessened by the discharge of mucus and blood, which characterizes the disease."—(*Lectures in Med. Gaz.* for 1832-3, p. 593.)—Ed.

† Perhaps, instead of representing increased peristaltic action as the proximate cause, it would be more correct to say, that the essential part of this disease consists in a preternatural augmentation of the peristaltic motion, and of the intestinal secretions; the predisposing causes being a peculiar irritability of the intestines, and of their secreting vessels. To call increased peristaltic action the proximate cause must be inaccurate, since it exists in several other cases never comprehended under the name of diarrhœa. As a general rule, Drs. Crampton and Forbes join the best modern pathologists, in considering the seat of diarrhœa to be the intestinal mucous membrane: "and it is the state of this membrane, and not the discharge, which is to be regarded as the great object of attention. The only exceptions to this rule are the cases where the disease is excited by fluids poured into the intestinal tube from the annexed glands, or by irritants of a temporary kind, as food or medicines, applied directly to the membrane. Even in these cases, the secondary affection of the membrane is often of much more importance than the cause producing it." In the mildest forms of diarrhœa, it is conceived that a degree of irritability may exist in the mucous membrane. In another variety, there may be a morbid degree of excitement, or of increased action in the membrane, considered as a secreting and exhaling organ, whereby it throws out its fluids in a morbid state or quantity, or both. But in a still more numerous class of cases, more or less inflammation of the mucous membrane prevails, from simple slight congestion to alteration of structure. It may be confined to a small portion of the intestinal tube, or it may extend over a large portion of it. In this form of diarrhœa, the evacuations deviate greatly from the character of health, and consist principally of fluids secreted by the inflamed membrane being mucous, or serous, or flaky from admixture of coagulable lymph, and variously coloured, according to the condition of the liver, the ingestion of food, the previous

be increased, and consequently looseness or diarrhœa occasioned, firstly, by irritating materials thrown into them by the mouth; secondly, by a morbid change in the fluids which are naturally secreted in the intestinal canal; and thirdly, by an irritable state of the intestines themselves, or the membrane that lines their inner surface. Independently of which, the same effect may follow, in a variety of ways, from the readiness with which the intestines associate in the action of remote organs. Thus sudden passion or commotion of mind will frequently excite looseness; sudden cold or heat applied to the surface of the skin will do the same. [And among the diseases of other parts of the body which affect the intestines, the irritation of dentition in infants may be mentioned as a familiar illustration; as it is seldom difficult, without producing diarrhœa. The

treatment, &c.—(*Sec Cyclopædia of Practical Medicine*, art. DIARRHŒA.) According to the researches of Andral, dysentery, diarrhœa, and lenteria, are far from being constantly associated with one particular state of the alimentary canal. The changes observed in it after death are most commonly situated in the large intestines, sometimes affecting every part of them, sometimes only certain portions of the tube. Occasionally the cæcum alone is diseased; in other instances, the rectum. The whole of the small intestines may continue sound, and the abruptness with which the marks of disease often begin to show themselves immediately below the valve of the cæcum, is a remarkable fact. On the other hand, sometimes no vestiges of disease are found in the large intestines, and the termination of the small ones is the only part affected. Most commonly, both the lower end of the ileum, and a more or less extensive portion of the larger intestines, are the seats of alterations, which differ in kind from a mere vascular fulness to the most complete ulceration, or softening of texture. Neither do the morbid appearances bear any constant relation to the duration or symptoms of the disease; for, in a given number of subjects, as nearly as possible similarly circumstanced in the two latter respects, we may find in one only a simple hyperæmia; in another, a softening of the mucous membrane with redness; in a third, a pale softening of the same texture; in a fourth, an induration of it with various shades of colour; in a fifth, an enlargement of the follicles, without any other morbid appearances; in a sixth, ulcerations, varying in number and size; and, in a seventh, together with one or another of these affections of the mucous coat, diluent morbid conditions of the other tunics, such as thickening, infiltration with serum, &c. Even the symptoms fail to denote the particular kind of alteration that may exist in the intestines, and the very same morbid appearances sometimes occur in subjects who have had a serous, or bilious looseness, as are met with in other cases, where the assemblage of symptoms constitute dysentery. Frequently there is an entire absence of fever and pain, when the mucous coat has numerous ulcerations in it, surrounded with a red, brown, or black thickening of that texture. In a few examples, dissection reveals no morbid appearances whatever, and affords no explanation of the functional disorder. Then there are certain diarrhœas arising from a morbid secretion produced out of the intestines themselves, but passing through them to be discharged.—Andral, *Précis d'Anat. Pathol.*, t. ii., p. 201.—Ed.

sympathy between the skin and the bowels is particularly great in many individuals, so that exposure to damp or cold air, or wetting the feet, will generally bring on a diarrhœa. Looseness of the bowels is frequently attendant on measles, scarlatina, and other exanthemata. In these last examples, an excited or inflammatory state of the mucous membrane accompanies the disorder. Diarrhœa is also a frequent and a most dangerous assailant in the advanced stage of a great variety of diseases, as fevers, phthisis,* chronic hepatitis, lumbar abscesses, diseased joints, &c.; completing that prostration of strength usually seen a little before their fatal termination.] But as all affections of this last kind are evidently cases of mere sympathy, they must be excluded from the history of diarrhœa considered as an idiopathic disease; and even in their treatment can only be remedied by remedying the primary complaint. [Cholera and dysentery often commence in the form of diarrhœa.]

The subdivisions of diarrhœa may be resolved into the seven following:—

- | | |
|-------------------|---------------------|
| 1. Diarrhœa Fusa. | Feculent Looseness. |
| 2. ——— Biliosa. | Bilious Looseness. |
| 3. ——— Mucosa. | Mucous Looseness. |
| 4. ——— Alba. | White Looseness. |
| 5. ——— Lienteria. | Lientery. |
| 6. ——— Serosa. | Serous Looseness. |
| 7. ——— Tubularis. | Tubular Looseness. |

SPECIES I.

DIARRHŒA FUSA.

FECULENT LOOSENESS.

THE FECES OF COMMON QUALITY, BUT IMMODERATELY LOOSE AND COPIOUS.

This species generally works its own cure without the aid of medicine; for its common cause is food eaten to excess, or intermixed with an undue proportion of irritating materials, saline, saccharine, or vinous; in consequence of which it passes rapidly, and not thoroughly digested, from the stomach, and urges the intestines to an undue degree of activity. Hence often, antecedently to the looseness, there is a sense of sickness, and perhaps a few slight torminal pains. But if the disorder do not prove its own remedy, it is easily removed by any common purgative. In weakly stomachs, or where the intestines are sluggish, this mode of diarrhœa is also occasionally produced by a re-

tardation of the aliment, till it irritates from acescency, putrescence, or superabundant accumulation; and where it is not checked in due time, it will occasionally, like several of its cognate species, run into a chronic form, and prove extremely troublesome and obstinate. In some cases it has lasted for two (Riedlin, cent. iii., obs. 90), and even for three years (Forrestus, lib. xxii., obs. 3), and it then requires to be restrained with caution; for a sudden transfer to a state of costiveness has often produced some other severe complaint. And the same remark may be applied to the diarrhœa that occurs during dentition, which ordinarily keeps off febrile irritation; and, when violent, should be moderated, but not subdued.

This species is also produced occasionally by sudden exposure to cold, and especially by cold bathing; by great agitation of mind, and particularly that of fright, or anger, sometimes even when those passions have merely existed in dreaming (*Ephem. Nat. Cur.*, dec. i., ann. iii., obs. 234); and occasionally also by the bare sight of a purgative or other medicine which the patient is reluctant to swallow. All these are instances of sympathetic action, which has sometimes shown itself in perhaps a still more extraordinary way, where there has been a peculiar irritability of habit. Thus Borrichius relates a case in which it was produced by introducing a globule of black hellebore into an issue in the arm.—(*De Qualitat. Occultis*, 1715.) [In certain individuals this idiosyncrasy is so strong, that particular articles of food quite inoffensive to the generality of people will invariably bring on diarrhœa. The complaint is frequently produced by a sudden change of diet, as from an animal to a vegetable one; or by a change of the water, or bread, to which we have been accustomed. In this species of diarrhœa, as indigestion and crudities in the stomach are frequently the cause of the complaint, emetics have often been found serviceable. But purging has been supposed to be still more necessary to remove the crudities that have passed into the bowels. The celebrated Cullen believed, however, that this practice is founded on very erroneous notions. It rests upon the supposition of an acrimony present in the intestines, that ought to be carried off by purging. But from whatever source the acrimony proceeds which can excite a diarrhœa, it may be considered, he says, sufficient to evacuate itself, so far as that can be done by purging. Dr. Bateman pronounces this opinion extremely rational, and observes, that when merely opposed to the indiscriminate use of purgatives in diarrhœa, its justness is undeniable. But he believed that Dr. Cullen, in avoiding one extreme, gave a sanction to another. In a recent case of idiopathic diarrhœa from excesses at table or cold, a gentle purgative is seldom, if ever, in the slightest degree hurtful. However plausible the supposition that the irritating matter in the bowels will invariably purge itself off, experience proves that it is frequently very imperfectly voided, and that a part of it remains behind, keeping up a degree of irrita-

* The diarrhœa generally occurring in the latter stages of phthisis, depends on ulceration of the mucous membrane. The ulcers are sometimes very numerous, and scattered over the greater part of the intestinal canal: at the extremity of the ileum, however, they are more commonly found than in any other situation.* On this subject valuable information is contained in the works of Andral.—Ed.

* Dr. Stokes, of Dublin, in his Lectures on the Theory and Practice of Physic, alludes particularly to this fact, and states that a blister applied to the abdomen will often arrest diarrhœa in phthisical patients, when other remedies have been used without success.—D.

tion often continuing the disease, and even converting it into dysentery. Whenever any material degree of tenesmus is observed, a purgative is generally indicated; and if the bowels be very irritable, opium may be combined with it.*—(ART. DIARRHŒA, in *Rees's Cyclopædia*.) In these cases, calomel and ipecacuanha, calomel and rhubarb, or rhubarb with the tinctura or confectio opii, are invaluable medicines. When the case resists these medicines, small doses of the chalk mixture, with the tinct. catechu, the compound powder of kino, and tinct. opii, may be exhibited; and in very long protracted, unyielding examples, the camphire mixture with nitrous acid and opium,† or the sulphate of copper joined with opium, may be given twice a day, in the dose of half a grain, gradually increased to that of a grain and a half, as recommended by Dr. Elliotson.—(*Med. Chir. Trans.*, vol. xiii.) In every form of diarrhœa, the diet is a most important consideration: it should consist of milk, rice, arrow-root, tapioca, sago, jelly, beef-tea, or broth. In particular, all malt liquor should be avoided, and weak brandy and water, wine and water, or barley-water, preferred.‡]

SPECIES II.

DIARRHŒA BILIOSA.

BILIOUS LOOSENESS.

THE FECES LOOSE, COPIOUS, AND OF A BRIGHT YELLOW.

FROM the highly bilious tincture of the dejections, there can be no doubt that the bile, in this species, is secreted in a greater quantity than usual, and perhaps with an unusual degree of pungency; and hence the excess of peristaltic activity.§

* In cases of diarrhœa, the abdomen should always be swathed with flannel; warm fomentations also are sometimes useful.—D.

† R. Acidi Nitrosi dilut. ʒj. Misturæ Camph. ʒviij. Tinct. Opii guttas xl. Cochl. magn. iv., quarta quaque hora sumend. Recommended by Mr. Hope in *Edin. Med. Journ.*, No. 88. At the Bloomsbury Dispensary, a very efficient medicine for checking the diarrhœa which occurs in the fruit season, is found to be the camphire mixture, with ten grains of the subcarbonate of soda, and one drachm of the tincture of capsicum to each dose.—Ed.

‡ In the treatment of every diarrhœa, the first thing is to inquire into the cause. When the mucous membrane of the bowels is in a more or less inflamed state, and there is tenderness on pressure, as is illustrated in the diarrhœa of measles, diluents, astringents, and opium will not answer, unless leeches and a blister be applied to the abdomen. When the exciting cause is improper diet, this must be changed.—Ed.

§ This diarrhœa is not necessarily attended with any morbid change in the intestines, in which nothing but an unusual quantity of bilious matter is detected by dissection. The disorder, as Andral observes, is here brought on by a morbid secretion, not produced in the bowels themselves, but taking its course through them, in order to be discharged. When it is removed, the subjacent mucous coat is found quite unaltered, its vessels scarcely

The most common remote cause of this species of diarrhœa is a great and sudden increase in the temperature of the atmosphere, or a less than its mean degree of heat, operating for some weeks or months. Dr. Lind has justly remarked, that a rapid change of climate, whether from a colder to a hotter, or from a hotter to a colder state, is equally apt to excite diarrhœa. But the complaints hereby produced are of very different characters. That occasioned by sudden cold consists of an acrid mucous discharge, and will be treated of and explained under the next division. The diarrhœa excited by passing rapidly from a cold into a hot climate, belongs to the division before us, and depends upon an increased secretion of bile of bad quality. The calorific rays of the sun exercise a peculiar influence upon the organ of the liver, and soon stimulate it to an augmented action. In the intertropical regions, the quantity of bile hereby secreted is even more than the bile-ducts can conveniently carry off; whence some portion of it retrogrades, and is carried by absorption into the system, and is one of the causes, though not the only cause, of the darker hue of the skin in those quarters. In our own country, this species of diarrhœa is therefore found most commonly in the earlier part of the summer, when suddenly and vehemently bursting upon a cold spring; or in the autumn, when the liver has for many weeks been exposed to the effects of a very vigorous sun, and the whole system has become relaxed and debilitated. If at this time the atmosphere be pure, the disease is simple, and may be subdued without much difficulty; but if the rays of the sun should carry off the greater part, but not the whole, of the stagnant water from the fens and marshes of a country, and convert them into corrupt and offensive swamps, the atmosphere will be loaded with an effluvium of decomposed organized matter, animal or vegetable, or both, and the simple bilious diarrhœa will be converted into a remittent bilious fever; and hence, in few words, the common origin of the bilious autumnal fevers that so frequently prevail at the close of the summer season.

When the bilious diarrhœa is simple and unconnected with fever, it is seldom a formidable disease: a few doses of calomel, with a view of emulging the bilious pores of the liver, correcting the irritation of the organ, and taking off its increased action, with the assistance of mild diluents and demulcents, as infusions of lin-

more injected than natural. The source of the complaint, as well as of certain kinds of constipation, is in the liver. Every preternatural flow of bile into the intestines, then, is not invariably the effect of some irritation first existing in them. Other organs in the neighbourhood of the alimentary canal may accidentally communicate with it, and pour into it their different secretions, healthy or unhealthy. Thus, Andral has seen three cases, in which a purulent diarrhœa was kept up by the matter of ovarian abscesses passing through ulcerated openings into the rectum; and an interesting fact of the same kind is recorded by M. Dalmas.—See Andral, *Anat. Pathol.*, t. ii., p. 206, and *Journ. Hébd. de Méd.*, Nov. 1823.—Ed.

seed, quince-seeds, or comfrey-roots, for lubricating the intestinal canal, which has participated in the irritation, will usually prove a successful practice. The last was at one time a popular medicine in diarrhœas, and Dr. Cullen objects to its being omitted in the *Materia Medica* of the colleges. If the flux, and consequently the excitement of the liver, should still continue, opiates may be employed with advantage.

SPECIES III.

DIARRHŒA MUCOSA.

MUCCOUS LOOSENESS.

THE DEJECTIONS CONSISTING OF, OR CONTAINING, A COPIOUS DISCHARGE OF MUCUS.

THIS species bears a striking resemblance to the defluxion from the nostrils in catarrh. Its common cause is cold, particularly in the feet; the motions are acrid, often with but little bilious tinge; and like the nostrils in a catarrh, the lower part of the rectum is excoriated. It is hence denominated by many writers *catarrhus intestinorum*, and by Dr. Boerhaave *diarrhœa catarrhalis*.

The disease is, perhaps, also sometimes produced by acrid ingesta, as a coryza is occasionally excited by sternutories in those not accustomed to them. Here the process of purging will rather add to the complaint than diminish it; and copious diluents and demulcents afford the most rational mode of treatment; with which plan the daily diet should be made to coincide.*

This species of mucous or catarrhal diarrhœa, like the two preceding, is also frequently produced by any sudden change in the temperature of the atmosphere from great heat to great chillness; and hence its frequency and severity in passing rapidly from a warmer to a colder climate, as into the North Seas in the summer

* On this disease Dr. Stokes remarks, that the most efficacious remedies are the metallic astringents and the turpentes and balsams, combined with some of the preparations of opium: in severe cases of this gleet discharge, he uses the acetate of lead in free and repeated doses, and he has continued this remedy for six weeks without any apparent injury. He has used turpentine also with good effect. The same gentleman has recently drawn the attention of the profession to a form of chronic diarrhœa, occurring in persons of broken down constitution, or in those who have taken mercury freely. It is caused by small ulcers situated close to the verge of the anus; these produce irritation in the colon, tenesmus, griping, and frequent evacuations. The successful treatment of this form of disease consists in touching the ulcers with the nitrate of silver. Dr. Stokes recommends the anus to be examined in every case where the diarrhœa has been of long standing—has resisted a great variety of treatment, is combined with tenesmus, and a desire of sitting on the night-chair after a stool has been passed, showing irritability of the lower part of the large intestine; and, lastly, when the health of the patient does not appear to be so much affected, as it naturally should be where the intestine is much diseased.—(See Lond. Med. and Surg. Journal, March, 1834.)—D.

time. "In the outward-bound passage of the vessels in the whale-fishery on the coast of Spitzbergen," says Mr. Macartney Ross, "I have more than once had occasion to remark the very great effect of a transition into a cold latitude in deranging the state of the alvine discharge. The vessels destined for this often perilous voyage, generally leave England about the end of March, when the weather is comparatively temperate. A week or two serves to convey them within the Arctic Circle, in the course of which time few cases are beginning to appear. But after being fairly within the limits of the Frozen Sea, and encompassed with ice, so that the wind even carries with it a strong and penetrating frost, the cases daily increase, both in number and severity. The weather becoming progressively milder after the beginning of May, and the seamen by this time being more inured to the climate, few or no cases are met with; and such as do occur, I have always found to arise from the patient having been called suddenly from bed in the course of duty, and exposed to an intensely freezing atmosphere."

Where the looseness, of whatever species, is produced by a sudden chill on the surface, small doses of ipecacuanha, with or without opium, have generally been given with advantage.—(*Toxe*, Bibl. i., p. 118.) Fernelhuys (*An omni alvi fluxui radix Brasiliensis?* Paris, 1706) and Dr. Fothergill (*Med. Obs.*, vol. vi., art. 18) recommend it alone; Dr. Stoerck (*Klin. und Anat. Bemerk.*, p. 7), with more reason, in combination. And if the disease should become chronic, the warmer astringents should be had recourse to, as columbo,—to which also Dr. Stoerck recommends an addition of laudanum,—cusparia, and arnica (*doronicum pardalianches*, Linn.), which, though rejected in our own country, maintains its reputation all over the continent. Of the arnica root, Dr. Stoll used to give a drachm every two hours.—(*Mat. Med.*, part ii., p. 307; part iii., p. 163.)

SPECIES IV.

DIARRHŒA ALBA.

WHITE LOOSENESS.

THE DEJECTIONS MILKY, OR RESEMBLING IN THEIR APPEARANCE A MIXTURE OF WATER AND LIME, WITH A FROTHY SCUM.

[In the preceding editions of this work, the learned author described two species under the names of diarrhœa chylosa and diarrhœa gypsata. The first is the case denominated in Cullen's *Nosology*, "*diarrhœa cœliaca, quâ tumor lacteus, speciei chyli deijcitur.*" The appellation of chylous looseness, had it been merely used as a simile, would have been but of little consequence; but, promulgated as it has been by various experienced physicians, and even by Dr. Good himself, as derived from the really chylous nature of the excrement, it becomes a vehicle of error, and the judgment of the practitioner in the sick-room is too apt to be blinded by it.]

The colour of the stools, according to Dr.

Good, affords evident proof, firstly, that the bile, which gives the usual tinge to the feces, is either not secreted, or impeded in its flow into the intestines; and, secondly, that the food, after being converted into chyle, is not absorbed and carried into the system.

The non-absorption of the chyle must proceed from some mischief in the lacteals or mesenteric glands; which may either labour under such an inertness or torpidity as to render them incapable of carrying on their proper function, or may be so obstructed in their course as to be prevented from exercising their function, notwithstanding their being in a state of health.

[Dr. Rummel (*Hufeland's Journal*, June, 1825) has taken an excellent survey of the various descriptions of this supposed disease given by authors, and ably exposes the mistake they all committed in believing that there was such a disease as diarrhœa chylosa, the existence of which he completely disproves. It is to Dr. Graves of Dublin, however, that the profession in this country is under particular obligations, for his judicious notice of the erroneous doctrines broached concerning the white forms of diarrhœa.—(See *Dublin Hospital Reports*, iv., 46, &c.) A gentleman applied to him, after having suffered a good deal from an epidemic dysentery. The febrile symptoms and discharge of blood had ceased for many weeks; but the emaciation and weakness continued to increase. He had one or two natural stools daily, without tenesmus; but in the course of every twenty-four hours he experienced eight or ten sudden calls to stool, attended with an impossibility of resisting the bearing down and weight felt in the rectum. Each evacuation consisted merely of two or three table-spoonfuls of muco-gelatinous matter, which varied in colour and consistence, but generally resembled thick milk, or a puriform fluid, and occasionally a transparent jelly. This fluid was evidently a secretion from the mucous membrane of the rectum in a state of irritation or chronic inflammation. It is observed by Dr. Graves, that such a condition of a mucous membrane constitutes the disease denominated chronic blennorrhœa; and, when it occurs in the rectum, produces a disease which, on account of the white colour of the discharge, would formerly have been called fluxus cœliacus, and the evacuation attributed to the loss of chyle by stool; for the chyle was supposed to be formed, but not absorbed, or carried into the system. As Dr. Graves very properly remarks, it is even less surprising that Dr. Good should have retained the old species, diarrhœa chylosa, than that he should have inserted a new one whose existence rests upon still more doubtful evidence. This new species he named diarrhœa gypsata, in consequence of the evacuations resembling in their appearance a mixture of water and lime, which appearance he actually fancied to depend upon the presence of earthy particles in the fluid discharged. This view of the subject he also fortified by several ingenious but premature reflections on the power of animals to secrete lime, and especially on the presence of lime in the intestinal calculi.

Unfortunately, the main and essential proof of the existence of lime in the motions was wanting, all chymical analysis of them having been neglected. Dr. Graves has often seen stools of the colour here described, and so has the editor of this work, which colour was referable to the absence of bile, and a morbid secretion of white viscid mucus from the intestines. Viscid and whitish discharges from the mucous membranes lining the eyelids, bronchial tubes, urethra, vagina, &c., are, as Dr. Graves observes, extremely common, and depend on a state of irritation similar to that which produces the white and scanty alvine evacuations arising from the mucous membrane of the rectum. It is evident, says he, from the case I have related, that chronic irritation of this part may produce much constitutional disease. When, however, the affection extends beyond the rectum, to the other portions of the large intestines, it occasions symptoms still more urgent. That a similar state of the mucous membrane lining the small intestines may occur, and give rise to a white secretion from its surface, is proved by examination of their contents in persons who die of the East Indian cholera, in many of whom white milk-like stools are observed during life. On dissection, these stools are found to depend on a secretion from the small intestines. The diarrhœa alba, described by Hillary as occasionally epidemic in Barbadoes, probably arises from a similar cause. This latter name, as conveying no erroneous hypothesis, the editor ventures to recommend for all the cases comprised under the heads of diarrhœa chylosa and diarrhœa gypsata in the former editions of this work. It is a name that simply expresses the fact of the white colour of the motion, without involving the reader in any hypothesis respecting chyle or lime being parts of what is voided.

For a description of the disease to which the objectionable epithet gypsata was applied, Dr. Good says:]

I am chiefly indebted to a valuable paper of Dr. Baillie, communicated to the London College, and published in its Transactions.—(Vol. v., art. xii.) "The evacuation," says he, "consists of a matter resembling in its appearance a mixture of water and lime, which is generally very frothy on its surface. When the disease is violent, the discharges are copious and very numerous, of a pale colour and sour smell, and the froth looks like yest. When it changes to a milder form, the evacuations are still more or less pale, but of the consistence of pudding, and do not occur oftener than two or three times in twenty-four hours. The appetite is often good, but sometimes defective. The countenance thin and sallow, but not much emaciated. The pulse varies but little from the standard of health, but is rather disposed to acceleration. The tongue is generally covered with a white fur of moderate thickness: the urine of somewhat deeper hue than natural, generally clear, occasionally turbid. An examination of the abdomen discovers nothing unnatural. The bowels are apt to be distended with wind; but there is no tumour, nor sense of pain upon pressure."

The disease occurs most commonly in persons who have resided for a considerable time in a warm climate, or who have suffered from affections of the liver: but it is sometimes met with in persons who have never left England, or been conscious of any hepatic complaint. It takes place more commonly in men than in women, though chiefly so perhaps because men endure the evils of hot climates more frequently than women.

Sometimes there will be a state of amendment, indicating a cure. The motions become figured, and of a darker hue, but rarely of the deep colour of health. This improvement, however, is mostly of only a short duration, and the patient soon relapses into the habit of frothy dejections. Those who are afflicted often live for several years, but the disease continues with the changes just noticed, and they hardly ever fully recover. The mind, as in other diseases of irritable temperaments, seems to exercise some influence; for the symptoms are aggravated, or the exacerbations appear more frequently, under the embarrassments of business, or the agitations of anxiety. Repeated returns of the complaint at length wear out the constitution, and the patient sinks from corporeal exhaustion.

In the case formerly termed diarrhœa chylousa, and supposed to depend sometimes upon obstruction of the lacteals and mesenteric glands, and sometimes upon a scanty supply of bile, Dr. Good recommended the following practice. In the first case, he says, the object is to remove the obstruction, which may be best accomplished by active stimulants, as calomel. In the second, if calomel be given at all, it should be in very small doses; but the common preparations of zinc and iron offer a better chance of success: and the *rheum rhaponticum*, or English rhubarb, being very slightly aperient, and far more astringent than the *rheum palmatum*, a useful medicine in various kinds of looseness from relaxation, may here also be employed to advantage in doses of a scruple taken twice a day; and where a more powerful vegetable astringent is required, we may find it in the leaves and young twigs of the *rhus coriaria*, or common sumach; which, however, are chiefly cultivated in our own country for driers and tanners. The berries possess a like property, and are acid, austere, and cooling. To these medicines may be added blisters, or rubefacients to the abdomen.

[The editor of this work is not inclined to place much reliance on any part of the above practice, except the calomel and blisters. As the disease seems to be connected with a scanty secretion of bile, and a morbid state of the secreting vessels of the mucous coat of the intestines, small doses of calomel or the blue-pill, joined with opium, counter-irritation of the skin of the abdomen, and anodyne or astringent injections, seem to him the most advisable remedies at first; and they may be followed by tonics, and other alternatives, according to circumstances. In particular, the nitrous ether, and tinct. opii, which have been frequently ex-

hibited in the camphire mixture, in many inveterate cases of diarrhœa, with superior effect, should be recollected.]

In the examples characterized by the resemblance of the stools to a mixture of lime and water, Dr. Baillie, estimates the influence of medicine as very inconsiderable. Half a grain of calomel, three grains of pilulæ hydrargyri, or a few of the hydrargyrum cum creta, taken every night, or every second night, have occasionally produced some advantage, by stimulating the liver to a better and more plentiful secretion of bile, without impairing the strength of the constitution; and bitters, as cascarrilla or cusparia, combined with a few drops of laudanum, have also occasionally had their use. But according to Dr. Baillie, the benefit is often only temporary. [Since the period, however, when this eminent physician wrote his observations, experience has pronounced the sulphate of copper to be a valuable medicine for the relief of this and other forms of obstinate chronic diarrhœa. Dr. Elliotson prescribes at first, half a grain of it twice a day, joined with one grain of opium. The dose is afterward gradually increased to one grain and a half or two grains; and the diet consists of milk, arrow-root, beef-tea, and a little wine.—(*Med. Chir. Trans.*, xiii., 451, &c.)]

On the authority of Dr. Rummel, who had employed the extract of nux vomica, Dr. Graves (*Dublin Hospital Reports*, iv., 50) resolved to try the effect of strychnine in cases of diarrhœa alba. One twelfth of a grain was given, in the form of a pill, twice a day, and with a successful result. Dr. Rummel observes, that after endeavouring to remove the original cause of the disease, the best remedies are narcotics, combined with strengthening and astringent medicines. Nux vomica, he says, possesses a peculiar power in controlling blennorrhœa of the rectum. In the cases recorded by Dr. Rummel, he employed sulphate of iron and columbo, besides sulphur, which has a particular action on mucous surfaces. The cure was generally promoted with hyoscyamus or opium, joined with nux vomica.]*

* This form of diarrhœa, the *alba*, is occasionally seen among the inhabitants of some of our southern states, and sometimes succeeds repeated attacks of the bilious fever so prevalent at the south: it often follows also long-continued habits of indulgence in stimulating food, and the abuse of ardent spirits; and occurs likewise in those who are subjected to severe labour, and whose diet is indifferent and unwholesome: in short, those causes which primarily impair the tone and functions of the digestive organs, cause this disorder. The mucous surface of the whole alimentary canal is often affected by this complaint, and the stomach being capricious as to the quantity and quality of the food, its functions become after a while so impaired, that marasmus often ensues. The best treatment, unfortunately, is often unsuccessful; the blue-pill, and the hydrargyrum cum creta in limited quantities, are among the best mercurials. Salivation will inevitably do harm. The slight mercurial doses may be followed by the astringent resinous gums, as the catechu or the kino, blended with chalk and a little camphire in

SPECIES V.

DIARRHŒA LIENTERIA.

LIENTERY.

THE DEJECTIONS CONSISTING OF THE ALIMENT PASSED RAPIDLY, AND WITH LITTLE CHANGE.

THE signs entering into the definition of this species prove sufficiently in the first place, that the stomach is in a morbid state, and that the gastric juice is not secreted in a proper quantity or with proper qualities; and next, that the bile is either not duly secreted, or else obstructed in its passage; for were there a free flux of it, the feces, however crude, would display their common yellow hue, which they rarely exhibit. [According to other writers, however, lenteric diarrhœa depends upon a morbid irritability of the stomach and bowels,* whence the food is prematurely expelled from the former organ into the intestinal canal, in an imperfectly digested state; and the bowels themselves being also morbidly sensible, very quickly void whatever they receive. The motions are at the same time loose and liquid, the exhalant vessels and excretories of the mucous glands pouring out an abundant quantity of their respective fluids. The disease is generally accompanied with great weakness of the digestive power, as well as morbid irritability of the stomach.] Lientery (λιεντερία), lubricitas intestinorum, was the name given to this disease by the Greeks, and it is here retained. The Latins, with a loose translation of the term, called it *levitas intestinorum*; and the general idea expressed by both is, that the aliment passes lightly or fleetly along, and with little elaboration by the intestines; whose peristaltic action is at the same time quickened.

[The view taken by Dr. Good of the causes of the present disorder, led him to recommend the general plan prescribed for dyspepsy. According to other physicians, however, the indications are first, to lessen the irritability of the whole alimentary canal, by the exhibition of opium, joined with astringents and absorbents; secondly, to increase the digestive power of the stomach, by the administration of tonic bitter medicines, as the infusion of cascarrilla, gentian, or orange-peel, the decoction of cinchona, or small doses of the sulphate of quinine. Moderate exercise, especially on horseback, will tend to re-establish the functions of the stomach; and

the form of a julap. The late Dr. Richard Bayley, of New-York, used freely a decoction of the simarouba. The practice of Dr. Elliotson has long been known among us: and the sulphas ferri in like doses, blended with half a grain or a grain of opium, is also administered as a judicious tonic. We are not aware that any of our practitioners have used the strychnine in this affection.—D.

* Bateman, in Rees's Cyclopædia, art. LIENTERY. As if physicians were never to agree, it is the opinion of Drs. Crampton and Forbes, that "the variety (of diarrhœa) termed *lientery*, in which undigested aliment appears in the stools, has no claim to be considered as a distinct form of diarrhœa, as the circumstances supposed to characterize it may occur in every species of the complaint."—Cyclop. of Pract. Med., art. DIARRHŒA.—ED.

all cold articles of diet, or such as are difficult of digestion, should be avoided; particularly salads, and other raw vegetables. Dr. Bateman once witnessed a severe attack of lientery, brought on by eating a little ice-cream, when the patient had been previously suffering from indigestion; the enfeebled digestive powers seemed to sink at once, and the food was discharged almost unchanged. When the alimentary canal is in the abovementioned irritable state, the invalid should refrain from exercise immediately after meals.]

SPECIES VI.

DIARRHŒA SEROSA.

SEROUS LOOSENESS.

THE DEJECTIONS ALMOST ENTIRELY LIQUID AND LIMPID.

FROM the thin fluidity of the stools in this species, Hoffmann has described it by the name of *diarrhœa aquosa*. It is evidently dependant upon a very irritable state of the excretory vessels of the intestines; and sometimes holds the same relation to the third species, *diarrhœa mucosa*, as the limpid defluxion of an incipient catarrh does to the mucous discharge in which it terminates. Yet the irritation is here much greater than in mucous diarrhœa, often produced by different causes, and frequently requires a different mode of treatment. The mucous diarrhœa, or indeed any of the preceding, may run into it if long continued; for the common cause of the irritation is debility of the excretories. Here again it must be obvious that purging of any kind would be mischievous: and the most effectual plan of success that has occurred in my own practice, has been the use of warm astringents and gentle stimulants or tonics.

The simarouba (*quassia simarouba*) is particularly entitled to our attention, and will indeed be found useful in most of the species of the genus before us; as will also, in many cases, the lopez-root (*lopezia mexicana*), which by Gaubius (*Adversar*) was preferred to the simarouba, and which seems to operate at least as much by tranquillizing the irregular or spasmodic action of the intestinal canal, as by any astringent power it may possess. The *gum urbanum*, Linn., better known by the official name of caryophyllata, or herb bennet, was formerly in high repute for all complaints of this kind; its taste is aromatic and austere.

The *punica granatum*, balaustine, or pomegranate-tree, is still continued in several pharmacopœias, and employed in practice in this and the preceding species, both in the flower and bark: the latter seems to have been a favourite medicine with Dr. Mead, who prescribed a decoction of it, with red roses and cinnamon, in various diarrhœas proceeding from debility. Cullen (*Mat. Med.*, vol. ii., p. 44) thinks highly of it. It is indeed a powerful astringent, and as such is entitled to attention; but it has a roughness so unpalatable as to disqualify it for general use. Where these cannot be retained on the stomach,

alum alone may often be given with advantage; and Dr. Cullen expresses his surprise that it is not employed more frequently or more freely. His dose is four grains at first, and afterward a scruple several times a day.*

Where the disease is of very long standing, we often gain great benefit by uniting a tonic or astringent with a diaphoretic, thus strengthening the bowels, while we take off irritation by exciting a transfer of action on the skin. Upon this principle Dr. Fordyce proceeded when he prescribed a combination of tormentil and ipecacuanha. A like transfer of action has sometimes been attempted by issues, blisters, and setons. Hippocrates (Περὶ Πάθων, lib. iii., p. 523), with more reason, employed for the same purpose emetics, and has been followed by Fontaine, and other practitioners; and Malvachini, with the same view, recommended diuretics.—(*Utiles Collectiones.*) Dr. Lind (*On Diseases in Hot Climates*) and Dr. Adair (*Med. Commentaries*, &c.) have recommended the native carbonate of zinc, or official calamine in fine powder.

In a very obstinate case that fell to my lot a few years ago, in which the patient, a young woman of twenty-four, had, for ten years, never passed fewer than nine or ten watery stools a day, sometimes tinged with blood, and often accompanied with great spasmodic pain, I found the disease yield in a few weeks to camphire mixture and pills of the resinous gums, after that, as I had reason to believe, all the usual routine of astringent earths and salts, astringent purgatives and narcotics, had been tried, and spent their force in vain. It is probable that, in some cases of this kind, the superacetate of lead, in doses of a grain, combined with three or four drops of laudanum, might prove equally useful. [Here, also, the sulphate of copper, in the dose of half a grain, gradually increased to a grain and a half, joined with opium, and given twice a day, merits trial, the experience of Dr. Elliotson being strongly in its favour.]

This disease is also occasionally produced by drastic purges, as elaterium; and is often critically employed by nature to carry off dropsies, and some other remote accumulations of fluids

SPECIES VII.

DIARRHŒA TUBULARIS. TUBULAR LOOSENESS.

THE DEJECTIONS CONSISTING MORE OR LESS OF MEMBRANE-LIKE TUBES, WHITISH, VISCOUS, AND INODOROUS.

I HAVE never hitherto seen this species arranged, and not often described; but it occurs frequently in practice; and appears to depend upon a peculiar irritability of the villous membrane of the larger intestines, which, in con-

* In large doses it occasions nausea, vomiting, colic, and purging; in small ones, constipation. In old diarrhœas, when ulceration of the mucous membrane exists, alum may cause mischief.—See A. T. Thomson's *Elem. of Mat. Med.*, vol. ii., p. 59.—Ed.

sequence, secrete an effusion of coagulating fibrin, fibrin mixed with albumen, instead of secreting mucus, occasionally accompanied with some degree of chronic inflammation. It has a striking resemblance to the fibrous exudation thrown forth from the trachea in croup, but is usually discharged in longer, firmer, and more compact tubes. There is commonly a considerable sense of heat and uneasiness in the rectum; and upon evacuations, the sphincter, partaking of the irritability, contracts so forcibly, that the feces are discharged with great pain and of very small calibre.

From the laminated appearance of this effusion, it has generally been mistaken for a separation of the mucous membrane of the intestines; with which it seems to be confounded by Dr. Simson (*Edinb. Med. Essays*, vol. v., p. 153); but the exudation has no vascular structure, will not bear extension, and loses its form as soon as handled. At the time of writing I have a case of this description under my care, in a lady of delicate habit, twenty-eight years of age, who has been long labouring under a peculiar irritability of the rectum, giving rise to some degree of chronic inflammation, and a forcible contraction of the sphincter on evacuations. She has already discharged this kind of effusion for six weeks, and in tubes so perfect as at first to excite no small alarm in the attendants who noticed it. It is now, in some degree, on the decline, both in quantity and tenacity.

M. Bauer, in his letter to M. de Hahn (*De Morb. Intest.*, Dresd. 1747), gives similar examples; and a like case is described by Spindler, in which the secretion was worked up into a "materia alba, longa, compacta."—(Obs. 45.) It has sometimes assumed the exact shape of the intestine, as though this had cast off a tunic.—(*Act. Nat. Cur.*, vol. v., obs. 126.)

I have said that the discharge in this species proceeds chiefly from the large intestines; and I have seen it so often as to have had sufficient opportunity of determining with tolerable accuracy the part of the canal affected. From a valuable article, however, of Dr. Powell's (*Med. Trans.*, vol. vi., art. vii.), it appears at times to take place in the narrower portion of the intestinal tube, as high up, indeed, as the duodenum; for we are told that it was accompanied with acute pain in the epigastric region; that the stomach was highly irritable; and that it was followed by symptoms of jaundice or obstructed bile.

From a small increase in the pulse, and a coating on the tongue, there seems to have been here also a slight degree of inflammatory action, though so inconsiderable that Dr. Powell questions whether there was any whatever; but adds, which my own experience leads me most fully to confirm, that the disease is certainly not "disposed to assume that peculiar irritative quickness of pulse which marks enteritis."

That the affection described by Dr. Powell belongs to the present species, will appear evident from his description of the material evacuated, which seemed "to have formed parts of

an extensive adventitious membrane of no great tenacity or firmness."

"In the first of the cases," he adds, "which came under my notice, this membrane was passed in perfect tubes, some of them full half a yard in length; and certainly sufficient in quantity to have lined the whole intestinal canal. In others, also, the aggregate quantity has been very large, and it has continued to come away for many days, but it has been in thin irregular flakes, of not more than two inches extent, and not, as far as I could discover, of the perfect tubular form." And he afterward compares the membranous material thus excreted to that "formed in the trachea, under croup; but the symptoms," says he, "are there more violent and destructive from locality of situation."

From the acute degree of pain which the disease thus situated produced, and must necessarily produce, in the smaller intestines, as also from the spasmodic constriction of the bile-ducts, and the common symptoms of jaundice, the passage of gall-stones was at first suspected, till the character of the intestinal discharge spoke for itself.

From a like effusion of fibrin in the uterus, Blumenbach has shown (*Comment. Soc. Reg. Scientiæ*, Gottingen, vol. ix.) that a tunica decidua has been occasionally produced through the excitement of an aphrodisiac passion alone, without copulation or impregnation; and Morgagni (*De Sed. et Caus. Morb.*, Ep. xlviii. 12) has given examples of so perfect a formation of

the same membrane by the irritation that takes place in painful menstruation (*paramenia difficilis*), as to render it difficult to be distinguished from that belonging to an ovum. So corpora lutea have been formed, and their cicatrices occasionally found, in the ovaries of virgins.

The milder preparations of mercury, employed as alternatives rather than aperients, have frequently proved serviceable; and the balsam of copayva still more so. The last is indeed generally useful in a chronic inflammation or irritable condition of the secretions of mucous membranes; and in the disease before us, where I have not been able to induce the patient to take it by the mouth, I have recommended it in the form of injections. In one case in which I prescribed it in this form, three drachms, intermixed with three ounces of mucilage of linseed, being thrown up three times a day, it proved eminently useful.

Common emollient injections, moreover, employed in much larger quantities, where the sphincter will allow the pipe to pass up, afford temporary ease; and a diluent and anodyne injection of warm water and laudanum alone, repeated twice a day, still more benefit. In the meanwhile, the mercurial preparations just adverted to, and especially the blue-pill, or Plummer's, which is still better (the pil. hydrarg. submur. comp. of the London College), should be taken in a dose of four or five grains every night: and, if necessary, the bowels kept open by two drachms of sublimed sulphur daily.*

* Sauvages has mentioned a *diarrhœa adiposa*, in which liquid or solid fat is discharged from the intestines. On this subject the most instructive document is a paper inserted by Professor Elliotson in the last volume of the Transactions of the Medical and Chirurgical Society of London, entitled, "Observations on the Discharge of Fatty Matters from the Alimentary Canal and Urinary Passages." This paper contains, indeed, all that is known on the curious topic to which it relates. Dr. Elliotson begins his remarks by adverting to the formation of ambergris, or gray amber, a fatty substance, consisting chiefly of what is termed ambreine, which is analogous to cholestérine, and supposed to be produced by disease in the alimentary canal of the spermaceti whale (*physeter macrocephalus*). Some declare that this fatty substance is never seen higher than six or seven feet from the anus, and a mass weighing 182 pounds has been found in the animal.—(*Phil. Trans.*, 1783.) Dr. Elliotson next remarks, that fatty matters, which have an external origin, are occasionally discharged from the human alimentary canal, and that castor-oil is frequently seen liquid in the evacuations.—(See *Riverii Obs. Med.*, cent. ii., obs. 23, and the German *Ephein*.) But old authors detail instances of fatty discharges from the intestines, that do not appear to have originated externally; "and (says Dr. Elliotson) of every variety of those old cases I can adduce a modern and indisputable example. In some instances the fat was discharged solid." In a case related by Moellenbroccus, it was not unlike the fat of beef; and in another, recorded by Mæbius, a daily discharge of a substance exactly like human fat occurred. Among other examples, Dr. Elliotson refers to a weaver, whose case is detailed in the Medical Essays for 1752. The matter, voided with his excrement, was a whitish substance,

about the bulk of a large walnut, and like tallow or hardened marrow, composed of small globules. For various other instances on record of the evacuation of solid fat, the editor refers to Dr. Elliotson's paper. On other occasions the fat is discharged liquid, and then concretes into the appearance of butter. The learned Professor of Physic in the London University quotes a case of this description from Tulpus.—(*Obs. Med. Amst.* 1685.) The yellow fatty substance, when thrown into the fire, burnt with a bright flame. He also reminds us of the specimen of such fat preserved in the Museum of the College of Surgeons, and voided by a child four years and a half old. The case was related by Sir Everard Home, as a proof that fat is sometimes formed in the intestines. Dr. Elliotson met with two cases of fatty evacuations, and he has described the appearances found on dissection in these and another example. One patient, a weaver, aged forty-five, was admitted into St. Thomas's hospital, labouring under phthisis and diabetes mellitus. Soon after his admission, he complained of excruciating pain in the abdomen and in the back, and had diarrhœa. In his stools, which were often rather pale, a yellow substance was noticed, like concrete oil. On putting it into the fire, it burnt with a large flame. He continued to discharge more or less of this till his death. Long before, his urine became excessive; it seems that he had voided blood from his bowels, and that as soon as a matter like butter began to pass, the bleeding ceased and pain commenced. The fatty substance was examined by Dr. Prout and Mr. Faraday, who were satisfied of its oily nature. At length the patient grew thin and weak from the combined effects of ulceration of the lungs, the discharge of sugar from the urinary organs, great suffering, and the discharge of fat from the bowels. On examination

GENUS IX.

CHOLERA.

VOMITING AND PURGING.

ANXIETY, GRIPINGS, SPASMS IN THE LEGS AND ARMS, WITH VOMITING AND PURGING, OR FLATULENT ERUCTIONS AND DEJECTIONS.*

CHOLERA has, by several late and present writers of distinction, been regarded as a mere species of some other genus, as DIARRHŒA, which is the view taken of it by Dr. Young; or as a mere variety of some particular species, as *vomit*, which is the place it holds in Dr. Parr's nosology. It is not always, however, accompanied with a diarrhœa; and, even where it is so, the constant tendency it evinces to an extensive chain of spasmodic actions, gives a striking character to the disease, and justifies its being arranged and treated of as a distinct genus. From vomit, it is still more widely discrepant.

after death, all the intestines looked yellow and greasy, as though they had been soaked in oil. Numerous black points were seen in some parts of their mucous membrane, like those frequently noticed after fever and chronic diarrhœa. But no other morbid appearances existed in the alimentary canal. The liver was healthy, and the gall-bladder full of thick, dark bile. The pancreatic duct and the larger lateral branches were crammed with white calculi. The kidneys were sound; the lungs tuberculated and ulcerated.

Dr. Elliottson was shown, by Mr. Pearson of Clapham, a woman who voided both solid and liquid fat. She died of this complaint and phthisis. Her liver was enlarged and painful; her urine scanty and pale; she was generally relaxed, and the evacuations preceded by pain. For many months she vomited several times a day. The feces were very pale, and almost destitute of smell. She passed daily about two ounces and a half of fat, and a third of an ounce of oil; but the quantity of the latter varied considerably. After death no disease was discernible in the alimentary canal or urinary organs. The liver was healthy in structure, but very large and pale, destitute of bile, no less than the gall-bladder, which contained a thick, greasy mucus, not inflammable. In one case, communicated to Dr. Elliottson by Dr. Prout, the cœcum was found much thickened, and the mucous membrane of it and the colon ulcerated.

Dr. Elliottson afterward quotes an example from Tulpus, in which fat was voided both from the bowels and bladder, a modern case of which he has also adduced in a lady of his acquaintance. It seems that Dr. Prout has several times noticed fatty matter that had been passed with the urine, and, in every instance, malignant disease of the kidney and bladder supervened.

"I have thus (says Dr. Elliottson) not merely adduced recent examples of all the old wonderful cases of this kind, and even one example of the most wonderful, in which oil passed from both the intestines and bladder; but have related one more extraordinary than any, in which while *pus*, a substance not found in the healthy body, was passing from the air passages, oil was passing from the intestines, and *sugar* from the urinary organs.

"It also appears that organic disease of neither the alimentary canal nor any other part is necessary to the disease, though, in all the cases that

The term CHOLERA is of ancient use, for we trace it in the writings of Hippocrates. Celsus derives it from *χολη* and *ῥεω*, literally *bile flux*; and Trallian from *χολας* and *ῥεω*, literally *intestinal flux*, as though the matter discharged from the alimentary canal were excreted by the intestines rather than by the liver. It is highly probable, that in all its species, we shall have to contemplate the liver as morbidly affected from the commencement, and the bile as some way or other damaged in its secretion, yet not always by too rapid and copious a flow, to which the disease has been generally referred. This, indeed, will be found ordinarily to take place in the first of the three following species; but, in the second, it appears to be injured by suppression rather than by excess; and in the third, by a change in its natural qualities, if, indeed, much of the fluid discharged in this species be not, as suspected by Trallian, in some instances, secreted by the excretories of the intestines. † Under either

have proved *fatal*, and been investigated, there have been found marks of disease in either the alimentary canal, the liver, or the pancreas; and, in many, decided disturbance of the liver occurred during life. The affection, accordingly, has sometimes been temporary, sometimes occasional; sometimes accompanied by various incidental symptoms; sometimes unattended by severe consequences, and sometimes has proved fatal; agreeing in these points with so many other diseases.

"It may be a question whether the fatty discharges from the bowels were derived from the liver or the intestines. The pain at the epigastrium and right hypochondrium experienced in some cases, the jaundice sometimes noticed, the total deficiency of bile in the motions of some of the patients, and the unctuous nature of most biliary concretions, together with the natural presence of unctuous substances in the bile, may favour the opinion of their hepatic origin. I am at a loss to say whether the completely oily appearance of the coats of the intestines, in the man whom I opened, favours the opinion of their intestinal origin. If this is their source, I am at a loss to which portion of the tube to ascribe them.

"In regard to treatment, the lady mentioned by Dr. Babington was always relieved almost at once by a few ounces of olive-oil, and Dr. Simpson appears to have cured two cases by the exhibition of an immense dose of it. In imitation of this practice, I gave my patient two ounces of olive-oil for two successive days, and four ounces on the third, which, however, he made two doses of, with the effect of vomiting and purging; and he certainly from that time discharged much less of the oily matter, and suffered much less pain in the abdomen and back."—See Med. Chir. Trans., vol. xix.—Ed.

* Dr. Brown thinks the following definition, which is a modification of that of Dr. Macann, will probably comprise every case really belonging to the genus cholera:—"Vomiting, purging, spasms, prostration, and collapse, or any form of these symptoms occurring simultaneously, or in a succession more or less rapid."—Cyclop. of Pract. Med., art. CHOLERA. This opinion may be correct. Especially if the species termed *wind cholera*, by Dr. Good, be put out of consideration.—Ed.

† In the spasmodic or malignant cholera here alluded to, the motions have no bile in them whatever, and are perfectly white and watery.—Ed.

derivation, however, the term is not incorrect, for the alimentary canal and the liver uniformly co-operate in the morbid action, and the fluid discharged is the result of such concurrence.

Some writers formerly, and many in the present day, have expressed this disease by the pleonastic term of cholera morbus; pretending that cholera, of itself, imports *anger* as well as the disease before us, and that *morbus* is added to distinguish between the two. I am not aware that the word cholera has ever been employed in a mental sense by any Greek writer, though several of its co-derivatives have been. It stands alone in Celsus and Galen; and if a distinctive adjunct were not necessary in their days, it must be wholly superfluous in ours. The following are the species that seem clearly to belong to this genus:—

1. Cholera Biliosa. Bilious Cholera.
2. ——— Flatulenta. Wind Cholera.
3. ——— Spasmodica. Spasmodic Cholera.*

SPECIES I. CHOLERA BILIOSA. BILIOUS CHOLERA.

THE VOMITING AND PURGING FREQUENT AND COPIOUS, WITH A REDUNDANCE OF BILE.†

This species is both sporadic and epidemic. Under the first form it is usually of slighter and shorter duration; and its common causes are, superabundant and perhaps acrid bile; suppressed perspiration, particularly by cold or damp applied to the feet, as in standing long on a moist soil in foggy weather; cold drinks, especially when the body is considerably heated by exercise; cold, indigestible fruits, as unripe apples or pears, cucumbers, melons, mushrooms; drastic purges taken in excess; and in one instance an excessive dose of emetic tartar (*Henrici Dissert. de Cholera Morbo*, Hal. 1740); a sudden fright, and particularly from thunder (*Phil. Trans.*, 1667), or any other rapid exhaustion of the sensorial power.

The causes are, therefore, many of them the same as those that produce several of the species of diarrhoea and colic; particularly *colica*

cibaria, or surfeit. Sydenham indeed observes, that the symptoms of the last and of cholera are alike, and the cure the same; yet adds that the diseases are of a different kind. In effect, the last is peculiarly distinguished by its wandering, or universal spasticity; and hence becomes a far more dangerous, because a far more general affection.

The epidemic form of the disease shows itself commonly at the close of summer, or the beginning of autumn—Sydenham says, as certainly as the appearance of swallows in the spring, or cuckoos about the dog-days; [and that it very seldom continues longer than the month in which it began. But this observation does not accord with the experience of the present times. Cholera is now seen perhaps more frequently in September than in August; and cases sometimes occur, though it be not epidemic, considerably earlier than August; even in June, or May.—(*Bateman, in Rees's Cyclopædia*, art. CHOLERA.)] One of the immediate effects of the caloric rays of the sun is to stimulate the liver to excessive secretion of bile; hence the alimentary canal is overloaded with it.* And hence, again, the greater violence of this complaint, and its accompaniment with peculiar symptoms in hot climates. In addition to this cause, however, which operates directly upon the body, there is another which operates indirectly upon the body, and directly upon the atmosphere; and that is, the ascent of an unhealthy effluvium from the decomposition of animal and vegetable substances that form the face of swamps, marshes, and other moist grounds; which predisposes the body to the action of this and other diseases as well; unless it be conceived that the particular epidemic results from a peculiar combination of the decomposing elements, so as to produce a choleric miasm, as, under another combination, they produce a febrile miasm; a subject well worthy of consideration as it relates to the third species of cholera.

It is not to be wondered at, therefore, that this disease should, in many instances, prove excessively severe. Its symptoms, indeed, are often dreadfully violent and rapidly fatal, as may

* For practical purposes, the division into ordinary cholera and spasmodic or malignant cholera, is sometimes deemed sufficient.—Ed.

† “Ordinary cholera may be thus defined:—Vomiting and purging, the discharges during the greater part of the disease containing generally a large proportion of bile; pain in the stomach and intestines; spasms, especially of the muscles of the abdomen and lower extremities, and prostration. If collapse occur, it takes place after the disease has endured some time, apparently as an effect of the great discharge, spasms, and irritation.”—(Dr. Brown, in *Cyclop. of Pract. Med.*) Professor Elliottson's description runs thus:—“At last, however, from the violent pain and profuse discharge, the body becomes cold, great faintness is felt, perhaps there is actual syncope; the patient sinks, becomes excessively weak, and then every thing occurs exactly as if hemorrhage had taken place. General convulsions occur, the spasms cease, and the patient dies as if he had lost an immense quantity of blood.”—(*Med. Gaz.* for 1832-3, p. 600).—Ed.

* Medical writers disagree on the question, whether in this form of cholera the liver is the part first disordered, or the alimentary canal primarily and the liver secondarily. Dr. Brown considers the first effect of the application of the cause of cholera to be a violent irritation of the mucous lining of the stomach and small intestines, which is then propagated to the liver.—(*Cyclop. of Pract. Med.*) This view seems to him to be more in accordance with the agency of the usually assigned causes of the disease, with its phenomena, the effects of remedies upon it, and the appearances on dissection. From the latter, perhaps, no inference can usually be drawn; for, as Andral observes, “Dans cette maladie, où les accidents terribles, qui surviennent du côté des voies digestives sembleraient se lier à des lésions intenses du canal intestinal, on ne trouve autre chose dans ce canal qu'une injection plus ou moins vive, qui ne diffère pas de celle qu'on rencontre, sur beaucoup d'autres cadavres, dans des cas où pendant la vie n'a même existé aucune affection grave de l'estomac ou des intestins.”—(*Précis d'Anat. Path.*, t. ii, p. 207).—Ed.

be seen from Dr. Sydenham's description, which is as follows : Vehement vomitings, and difficult and painful dejections of ill-conditioned fluids ; agony, and inflammation of the intestines and abdomen, cardialgy, thirst, a quick pulse, often small and unequal, heat and anxiety, nausea and colliquative sweat, spasms of the arms and legs, fainting, coldness of the extremities, and other symptoms, of equal danger, which terrify the by-standers, and kill the patient in twenty-four hours.*

Celsus, who has entered with more minuteness than is common to him into the diagnostics of this species, explains (*Medicin.* lib. iv., sect. xi.) more fully than Sydenham has done, the exact nature and appearance of the ill-conditioned discharges to which the latter refers. "Bilis supra infraque erumpit, primum aquæ similis, deinde ut in eâ recens caro lota esse videatur, interdum alba, nonnunquam nigra, vel varia."—"The bile bursts forth both upwards and downwards ; at first like water, afterward as though fresh flesh had been washed in it ; sometimes white, sometimes black or variegated." And he adds, accordantly with Sydenham, "quibus concurrentibus, non mirum est, si subito quis moriatur." "All these symptoms associating, it is not to be wondered at that the patient should die suddenly."

As the general commotion of the alimentary canal is to be referred in this species to a superabundance of bile thrown into it, and probably possessing a peculiar acrimony, our first object in attempting a cure should be, not to excite an additional flow by stimulants of any kind, and especially by violent purgatives and emetics, but to dilute and wash it out of the stomach and intestines by a free exhibition of mild demulcent fluids, as well injected by the anus as given by the mouth. And when this has been accomplished, the spasmodic action of whatever parts are affected may be advantageously attacked with opiates. This was Sydenham's practice, and it cannot well be improved upon.

Those diluents and demulcents are to be preferred which agree best with the stomach, and sit easiest and longest upon it. Celsus recommends a free use of water not quite cold, but only just deprived of its chill ; "aqua, neque ea ipsa frigida, sed potius egelida, danda est." Lie-nard, half a century before the time of Syden-

ham, gave it cold and fresh from the fountain, and, as he assures us, with great success.* And Cleghorn has recommended the same practice even in hot climates in our own times. Dr. Douglas was peculiarly attached to toast and water, which he made with oat bread boiled in the water ; the bread so thoroughly toasted, that the decoction was as brown as coffee. This has a slight astringency and a little mucilage, and may be a useful diluent. Dr. Douglas declares that he never knew it rejected in any case of cholera. Infusion of spearmint proves, also, a good anti-emetic, but it should be made with leaves fresh from the garden. Sydenham prescribed weak chicken broth for the same purpose, and applied it by injection to the rectum, as well as to the stomach. Linseed-tea or barley-water, with a little gum-acacia dissolved in it, may answer as well. As soon as the alimentary canal has been thus cleared of acrimonious matter, and the sickness subsides, opium, with or without relaxants, should be administered in repeated doses, to subdue the spasmodic action. Sydenham employed it alone, and in his favourite form of liquid laudanum, varying the dose from twelve to twenty drops in mint-water. Dr. Fordyce, with still more judgment, united it with small doses of antimonials, and thus increased its relaxant power.

But if the onset of the disease be very violent, and the pulse and the general health sink rapidly, opium must be given, and very freely, from the commencement.† Cholera is in all cases a very acute disease, and of short duration.‡ I have already observed that it has destroyed in

* Dissert. Ergo Cholerae Morbo Frigidus Potus? Paris, 1626.

† Dr. Elliotson joins with the diluent plan large doses of opium, and, in cases of extreme weakness, approves of brandy or other stimuli, and the hot bath. When the disease consists chiefly of vomiting, he thinks it advisable to determine a part of the bile downwards with calomel. If, after a time, a congestion of the head or any inflammation occur, the treatment must be regulated accordingly.—(*Med. Gaz.* for 1832-3, p. 600.) Dr. Brown is also an advocate for not deferring the administration of opium, which, in severe cases, he joins with calomel.—(*Cyclop. of Pract. Med.*) In slight examples he gives a grain of opium, or a proportionate dose of laudanum, every second hour, till relief be obtained. In those which are more severe, he prescribes two or three grains of calomel, with a grain of opium at the same interval, till three or four doses have been taken : or, the calomel being administered in a pill, a draught containing a proportion of laudanum, or black drop, equivalent to a grain of opium, may be taken along with it. If gastro-enteritis should come on, leeches and blisters on the abdomen, and three or four grains of the hydrarg. cum creta every fourth hour, till some affection of the mouth is perceived, are the remedies preferred.—Ed.

‡ This affection may last only a few hours, seizing the patient, for instance, early in the morning, and proving fatal in the middle of the day. Or it may last many days ; and if it subside, it may probably be followed by inflammation. Dr. Elliotson has frequently seen gastro-enteritis take place after the discharge had entirely ceased.—See *Med. Gaz.* for 1832-3, p. 600.—Ed.

* Sect. iv., chap. ii. As also *Epist. de Morb. Epidem.*, 1675-1680. At first, the discharge is sometimes thin and watery, and then the complaint has been called *white vomit*, but very soon pure bile comes away.—(*Elliotson*, op. cit.) The following description of certain serious symptoms, by Dr. Brown, is very correct :—"At the commencement of the attack the skin is generally warm and dry, but, after a few hours, its temperature falls considerably below the standard of health, and is bedewed with a cold and clammy moisture. The tongue is dry, and the thirst excessive ; the urine scanty, and high-coloured ; the pulse rapid, and generally small and irregular ; and the spasms, which affect the muscles of the abdomen and of the inferior extremities, and occasionally those of the hands and arms, recur at short intervals, and are attended with great pain."—Ed.

twenty-four hours. The symptoms generally abate on the second or third day, and the patient recovers rapidly. If there be any considerable degree of weakness on the decline of the disease, it may be necessary to have recourse to the warm and bitter tonics, of which columbo will be found one of the best.

[The following mixture is strongly recommended by Mr. Hope (*Edinb. Med. and Surgical Journ.*, No. 83, p. 39), of Chatham, for its efficacy in cholera:— \bar{R} Acid. Nitrosi $\mathfrak{Z}\text{℥}$, Mist. Camph. $\mathfrak{z}\text{viij}$. Misce et adde Tinct. Opii. xl . One fourth part to be taken every three or four hours.]*

SPECIES II. CHOLERA FLATULENTA. WIND CHOLERA.

THE VOMITING AND PURGING RARE, OR ABSENT ;
GREAT AND OPPRESSIVE FLATULENCE ; RETCH-
ING ; FLATULENT DEJECTIONS AND ERUCTA-
TIONS.

This species I have continued from Hippocrates, who denominates it, from the absence of liquid discharges, cholera, $\xi\rho\eta$, as Sydenham, by translating the Greek term, has done, *cholera sicca*.—(Sect. iv., cap. ii.)

In this species the bile, instead of being excessive in its flow, is obstructed or diminished in its quantity, and perhaps secreted with too low instead of too high a degree of pungency. The liver is evidently torpid and enfeebled ; and as flatulence is always a sign of debility, we have a full proof that the stomach and intestinal canal are in the same state. We have here, therefore, cholera grafted upon a dyspeptic habit ; and as, in dyspepsy, some quantity of air is let loose from most foods, whether solid or liquid, and an immense portion from many kinds, we are at no loss to account for the flatulence. The absence of evacuations is partly from spasmodic constriction, and partly from a want of wholesome bile ; and the retching does not pass into vomiting, because the diaphragm, on whose

expulsive co-operation the action of vomiting chiefly depends, forms a link in the entastic chain, as is obvious from the increased anxiety of the præcordia.

When cholera, therefore, is an epidemic malady, it will show itself under this form in persons of a highly dyspeptic idiosyncrasy, still more generally than when it appears as a sporadic disease. But the form is not a common one ; and hence in the epidemic cholera of 1669, Sydenham declares that he met with not more than a single instance of it : “Unicum,” says he, “duntaxat exemplum me vidisse memini ineunte hujus anni autumno.” And on this account Dr. Cullen has rejected the species altogether ; as others have transferred it to the genus Colica. But as the disease does exist, though it does not occur often, and as the distinguished symptoms of anxiety and spasms of the extremities, which peculiarly draw the line between cholera and colic, are equally present in this and the other species, we cannot disjoin them without confusion. They are produced by the same occasional causes, as surfeit, cold drinks upon a heated body, cold vegetables, as melons, inedible fungi mistaken for esculent mushrooms, poisonous animal and mineral substances ; they all take place sporadically, and all are at times epidemic.

The cure should be commenced with warm cathartics alone, or intermixed with opium, as the compound tincture of rhubarb, or of aloes. Usquebaugh, or the tincture of capsicum, has often also been found useful ; and when the paroxysm is removed, the restorative plan should be pursued, which has been already recommended for dyspepsy.

SPECIES III. CHOLERA SPASMODICA. SPASMODIC CHOLERA.

BURNING PAIN IN THE EPIGASTRIC REGION ; THE
DEJECTIONS WATERY ; INEFFECTUAL RETCH-
INGS, OR VOMITINGS OF A WHITISH FLUID ;

* A form of this complaint, which is sometimes produced by the irritation of teething, is very prevalent among children during the summer and fall months in the United States, and is also extremely fatal. We allude to the *cholera infantum*. By Dr. Hosack (*Med. Essays*, vol. ii.), this affection is considered as a febrile disease, analogous to the bilious remittent of adults ; and Dr. Butler seems very properly to have termed it the infantile remittent fever,—in which opinion the late Dr. Manu, of Massachusetts, also coincides. Accordingly, instead of prescribing anodyne and astringent mixtures to lessen the discharges from the bowels, Dr. Hosack recommends medicines to allay the febrile irritation, and directs that the stomach and bowels be emptied by small doses of ipecacuanha and rhubarb : calomel and antimonials are frequently prescribed with good effect in this disease. The former medicine, in small doses, according to Dr. James Jackson (*N. E. Journal*, vol. i., p. 336), is one of the most useful—perhaps the most useful medicine employed in this disease, as it answers four intentions. 1st, It excites the stomach and bowels to evacuate their contents. 2d, It excites a change in the actions of the secretory vessels of

those organs, and by sympathy produces similar effects in the liver and pancreas. 3d, In consequence probably of the last mentioned action, it appears to produce on the stomach the effect of a tonic. 4th, It occasions a more equal circulation over the whole body. The last effect is aided by frictions and warm bathing. Dr. Hosack remarks farther, “When the febrile symptoms are removed, weak brandy and water, or port wine and water, beef-tea, the liquor of oysters or clams, are useful in restoring the tone of the *primæ viæ*. But if the irritations of the intestinal canal continue after the febrile symptoms are removed, the chalk julap, with a little laudanum or paregoric, may judiciously be prescribed. In some instances, where the diarrhoea is attended with tenesmus, severe gripings, and the discharges are tinged with blood, small injections of starch and laudanum, or an infusion of rosemary (*statice limonium*, Linn.), are among the most effectual aids to lessen these evils. But of all the modes of preventing or curing this disease, none is so effectual as removal to the seashore, where the atmosphere is not only cooler, but in a particular manner restores the appetite and strength of the patient.”—D.

SPASMS SUCCESSIVE AND VIOLENT, OFTEN EXTENDING TO EVERY ORGAN; BLOOD DRAWN FROM THE ARM BLACK AND VISCID; GREAT DEPENDENCY AND PROSTRATION OF STRENGTH.

THERE is no species of disease that has of late years attracted more, perhaps none so much, attention, both at home and in the east, as the fatal cholera we are now about to consider.

We dare not say that it is an epidemic of modern origin, since it seems to be described by Bontius, and is supposed by some writers to be glanced at by several Greek physicians,* and even by Celsus. [Independently of the early notices left us by Bontius, and the more recent ones by Dellon,† in 1689, by Curtis and Paisley in 1774, and by Sonnerat from 1774 to 1781, Mr. Scott‡ endeavours to prove that it was described by the medical writers of the Hindoos, and particularly in a work ascribed to Dhanwantari, a mythological personage, corresponding to the Greek Esculapius. He also informs us that an epidemic prevailed at Arcot and other places about 1781, the occurrence of which was entered in the proceedings of the Madras Medical Board on the 29th of November, 1787, in the following terms:—"A disease having in October last prevailed in Arcot, similar to an endemic that raged among the natives about Paliconda in the Ambore Valley in 1769-1770, in an army of observation in January, 1783, and in the Bengal detachment at Ganjam in 1781, &c., as well as to an epidemic over the whole coast in 1783, under the appearance of dysentery, cholera morbus, or *mordyzim*, but attended with spasms at the præcordia, and sudden prostration of strength, as characteristic marks," &c. Mr. Scott adverts also to the occurrence of cholera in the Mauritius in 1778, and again in 1819; at Madras in 1782; at Vellore in 1787; at Arcot in the same year; in the northern Circars in 1790; and in the vicinity of Trincomalee about 1804. Some fatal cases are also reported to have occurred at Jaulnah in 1814.] The subject, however, is yet unsettled; and Mr. Annesley will not allow that the disease alluded to by Bontius, and still more lately by Sonnerat, is the exact disease before us.§ But we may at least affirm, that it has of late years assumed

an activity, fatality, and extent of range that it does not seem, from any history that has descended to us, to have possessed in earlier times; and that cannot be contemplated without horror: on which account it has been compared by Mr. Orton to the sweating sickness, and various other pestilences, that, with great fury and mortality, have ravaged the world in former periods.*

Some of the cases that occurred to Sydenham in the first species of cholera, and which we have already noticed, were so rapidly fatal, that this distinguished pathologist has also been conceived to have been acquainted with the present species, and to have included it under them. But his description does not seem to warrant any such conclusion; [for, he says, it prevails at the end of summer and during the autumn, as regularly as vegetation comes in spring; whereas this disease occurs at all seasons, and has no connexion whatever with heat. Sydenham describes it as a discharge of bile, and not of the peculiar fluid which we see in this affection.—(See *Elliottson in Med. Gaz.* for 1832-3, p. 628.)] Dr. Cullen, in like manner, upon a cursory view, might appear to have had his eye directed to it; for he has loosely copied Sydenham's remark, that cholera is sometimes so severe in its symptoms as to destroy life in twenty-four hours. But, on a more attentive survey, it will be perfectly clear that Dr. Cullen does not even, under this character, refer to the species before us; for he considers an increased secretion and discharge of common or yellow bile as a symptom belonging to every species of the genus; and contends that those cases which have not this mark are samples of diarrhœa, or some other disorder, but do not appertain to cholera.

Sauvages seems to have regarded cholera in all its species as a less momentous disease than even Cullen; for though he professes to follow Sydenham altogether in the mode of treatment, he takes no notice whatever of Sydenham's remark, that its symptoms are sometimes so violent as to destroy life in twenty-four hours. He has given, indeed, from Dellon, a species which he calls *cholera Indica*, but which differs very materially from the present, in being distinguished by delirium, a *strong* though unequal pulse, and a free flow of urine, both red and white, yet always limpid; as though the complaint were accompanied with inflammatory fever.

[It was from India and the adjoining countries, that the first clear and faithful descriptions of this species of cholera reached us; and even before the disorder had extended to Europe, the British practitioners in Asia had favoured us with so extensive a mass of communications that we were already in possession of a tolerably correct history of the general nature of the disease, how ignorant soever we might then be, and still are, of its remote cause; and Professor Cru-

* Scoutetten thinks that it was described by Wang-Chou-ko, a Chinese, who lived before Hippocrates, under the term *Ho louân*. The Hindoo physicians assert that the cholera has always existed in Hindostan.—(See *Med. and Top. History of Cholera Morbus*, translated by Doane. Boston, 1832.)

† *Voyage aux Indes Orientales*. Amsterd., 1689. It was intimated to Dr. Good by the Army Medical Board, that in a few official documents at the East India House, which were re-examined, the present disease is distinctly referred to, as having existed in the Bengal territory about a century ago, which will bring it only a little below the time when Dellon published his statement, and consequently give it confirmation.

‡ Report on the Epidemic Cholera, &c., by W. Scott, fol., Madras, 1824.

§ Sketches of the most prominent Diseases in India, &c., 8vo. Lond., 1825.

* Essay on the Epidemic Cholera of India, passim, 2 vols., 8vo. Madras, 1820.

veillier (*Anat. Pathol.*, 14me. livr., Paris, 1830) pays a very handsome and well-merited compliment to our countrymen in India, when he states that the observations subsequently collected at Moscow, Warsaw, Vienna, Berlin, London, and Paris, have only confirmed, or exhibited under new forms, the facts recorded in the modest accounts drawn up by our medical brethren at Calcutta. Not the slightest doubt, then, can be entertained of the absolute identity of the Indian and European cholera: hence their dependence upon some common, grave, and powerful cause, which overcomes all the circumstances of race, climate, temperature, season, and social customs; hence also the suspicion that the disorder was imported into Europe by the Russian army in its invasion of Poland.]

Among those who seem distinctly to have noticed it, though in a cursory way, are Sonnerat and Bartolomeo; the first of whom tells us, that it is called by the natives *mordezym*, a term which, according to Bartolomeo, Sonnerat has transformed, rather than translated, into *mort de chien*; but which I am more disposed to think is a corruption of the Arabic *MORDEKIE*, or *MORDECHIE*, the very name by which Delon says the natives denominated it, and which significantly imports "the death-blow:" according to Golius, *actio inferens mortem*; and hence synonymous with "*mors repentina*," or "*mors violenta*."

By the name of *mort de chien*, however, in what way soever derived, it is, according to Mr. Curtis (*An Account of the Diseases of India in 1782-3*, &c. Edin., 1807), most generally known in the present day, and particularly at Madras; and under this name, therefore, he has described it. To this gentleman we are indebted for one of the earliest histories of the disease that within the last fourteen or fifteen years has reached our own country; and which, added to Dr. Girdlestone's statement (*Essay on Hepatitis and the Spasmodic Affections of India*, Lond., 1787), began first of all to draw

the attention of British practitioners to its truly formidable character.

Mr. Curtis, whose history was published in 1807, regarded it, at that time, as a new disease; and finding no name for it in the nosological classifications, proposed, from its leading symptoms, to call it *SPASMODIC CHOLERA*; and it is thus denominated in the present work. From the absence of yellow bile, and perhaps of bile of any kind, by which the disorder is peculiarly distinguished, some of the writers in India have objected to the term cholera, as conceiving that such a term necessarily imports a redundancy of this fluid, and that too, of its natural colour, and other qualities; yet, as I have already had occasion to show, there is no such necessity whatever imposed on the term, but merely an understanding that the bile is morbidly affected in its secretion, either in quantity or quality of any kind, and consequently there is no reason for changing the term on this ground.* Nor are there always spasms in any part of the body; for the disease, at least as it has of late shown itself, in some cases destroys instantaneously, and before it has assumed its regular character; but I do not remember to have met with a single instance of its having run on for twelve hours without having developed this essential symptom.

Mr. Curtis informs us, that soon after the attack, "the spasms began to affect the muscles of the thighs, abdomen, and thorax, and lastly passed to those of the arms, hands, and fingers; but I never," says he, "then or afterward saw those of the neck, face, or back at all affected. The rapidity with which these spasms succeeded the attack, and their severity, especially as affecting the muscles of the thorax and abdomen, denoted in general the degree of danger in the case. The affection is a fixed cramp in the belly of the muscle, which is gathered into a hard knot with excruciating pain. In a minute or two this relaxes; is again renewed, or the affection passes to others; leaving the miserable sufferer hardly an interval of ease; and lastly,

* At the present day, many practitioners object to the name for a reason which our author has not considered. Certainly if only one stage of the disease were regarded, in which vomiting, purging, spasms, and prostration take place, the pathognomonic symptoms of cholera, the term *spasmodic cholera* would seem allowable; but, as Dr. Brown argues, "when it is remembered that the choleric symptoms, if not fatal, prove but the commencement of a series of changes, to which any one, who witnessed them alone, would give the appellation of *fever*, and which men of great experience in the disease have declared they could not distinguish from typhus; if we observe, too, that long before this epidemic excited attention, symptoms strikingly resembling those of cholera had been observed to form the initiatory stage of certain malignant fevers (see Dr. Negri's letter to Dr. Barry; Morton, *Pyretologia*, pp. 16, 13, 81; Torti, *de Febribus*, lib. iii., p. 124; and *Med. Essays*, by J. Brown, M. D., pp. 37-39), we are disposed to admit that it is really a fever, and that to designate it merely cholera is to take a part for the whole," &c.—(Dr. Brown in *Cycl. of Pract. Med.*) The name which this gentleman prefers is that sug-

gested by Dr. Johnson, namely, *epidemic choleric fever*. On the other hand, it might be argued, that a consecutive fever is not invariable; and one remark made by Drs. Russell and Barry is, that such fever is of more frequent occurrence in Russia than India. In the cases which the editor has had opportunities of seeing, in the King's Bench and elsewhere, if the patients recovered from the stage of collapse, febrile symptoms always followed, though in very different degrees in different examples. This observation accords with the following statement:—"We can positively assert, that we have not met with a single case in England in which fever did not intervene between the choleric or cold stage and restoration to health; and the result of inquiries we have addressed to individuals the most observing, and most familiar with the disease in this country, has proved that their experience has coincided with our own. It is true that in some cases this fever has been so slight, but the choleric stage has been so likewise; for we have always observed a correspondence in intensity between these stages."—(Dr. Brown in *Cyclop. of Pract. Med.*)—Ed.

it passes from one set to another, leaving the former free."

This account is supported by Dr. Johnson in his valuable "Essay on the Influence of Tropical Climates:" yet, as a proof that the Eastern cholera has of late assumed a severer and more fatal character, it is only necessary to observe, that the subsequent cramps, regarded by Mr. Curtis, and no doubt justly so, as indicative of the highest degree of danger, have, since the period to which his writings refer, been hailed as less ominous than many of the symptoms with which the disease now occasionally opens; and contemplated as a reaction of the system struggling against the first shock; proving that it has not been totally and instantaneously exhausted of sensorial power, as a Leyden vial is exhausted of its electricity by the discharge of the brass rod when applied to it.

The later and more fatal ravage I am now referring to, commenced its attack in August, 1817, at Jessore, about a hundred miles to the northeast of Calcutta; and spreading from village to village, reached Calcutta early in September, having destroyed thousands of inhabitants in its course. From Calcutta it extended to Behar, depopulating many large cities, and compelling the residents to flee for safety to other spots. Benares, Allahabad, Goruckpore, Lucknow, Cawnpore, Delhi, Agra, Muttra, Meerat, and Barcilly, all suffered in succession; the pestilence not diffusing itself at once, but travelling by a chain of posts, and attacking a second district after it had ravaged a first.

At length it reached the grand army, and spread through its different divisions at Muddellah, Jubbulpore, and Saugor, marching in terrible array over the Deccan. At Hussingabad its havoc was dreadful for several days; when, taking a course along the banks of the Nerbuddah, it alighted at Tannah. Having visited the famous cities of Arungabad and Ahmednugger, it spread to Poonah, and, in the direction of the coast, to Panwell, where it ramified north and south, crossed Salsette, and arrived at Bombay in the second week of September, 1818, a twelvemonth after its appearance at Calcutta.

While this was passing in the west of the Peninsula, the epidemic was making a like progress to the east and south, progressively extending over the whole Coromandel coast: whence it was reported to have spread, and a report that afterward proved to be but too true, to Ceylon; to the pure air and temperate climate of Siam; to Malacca; and, across the Straits of Sunda, to China; since which time, it has reached the Mauritius, and made its appearance on board vessels both in harbour and at sea. [In the summer of 1821, the disease first commenced its ravages on the borders of the Persian Gulf, after having raged in the earlier months of that year at Bombay. In

1823, it had extended itself, in one direction, to the shores of the Caspian Sea, and, in another, as far as the Mediterranean, making an apparent stand at Astrachan, and in the neighbourhood of ancient Antioch.* At this period, therefore, it very closely threatened Europe. It had passed over 90° of longitude and 66° of latitude; having, in one direction, crossed the equator, and approached the boundary of the southern tropics; and, in another, traversed the northern tropic into the temperate zone.]

The diagnostics of this extraordinary pestilence are admirably furnished for the period before us, by Mr. Whyte, assistant surgeon to one of the divisions of the army, whose description I shall copy; premising that, while in the centre division the spasms preceded the vomiting and purging, in the others they generally came on after the appearance of these symptoms.

The disease, says Mr. Whyte, commonly begins with a watery purging, unattended with griping or any pain. At an interval of generally from half an hour to five or six hours, and sometimes without any interval, the patient vomits a white fluid uncombined with bile. The spasms, in the division of the army from which this description is drawn, made their attack at no determinate period of the disease; but, in general, not for many hours after the commencement of the vomiting and purging. There was soon great debility and sinking of the pulse; the extremities became cold; the eyes sunk in their sockets; the vessels of the tunica adnata were injected with red blood, over which, if the disease advanced, a film was formed; the features expressed the deepest anguish; and the eyelids were either wholly or half closed. The patient invariably complained of great heat at the stomach, and called incessantly for cold drink. The tenesmus now became violent, while nothing was discharged but the fluid just noticed, and a substance like the coagulated white of an egg. The uneasiness and jactitation were so great, that it was with the utmost difficulty an opportunity could be got of feeling the pulse, which by this time was not always perceptible, although it was generally so till the spasms came on. These were always of the rigid kind, attacking first the toes and legs, and then extending to the thighs, chest, and arms. When they reached the chest, the breathing became so difficult, and the sense of suffocation so extreme, that the diaphragm most probably associated in the spasmodic action. [In one case, mentioned by Mr. Scott, where a man had been paralytic in his limbs, with a total numbness of them, they were severely affected with spasms, and became exquisitely sensible.]

The most unfavourable and dangerous signs in the ordinary progress of the disease were, a coldness of the surface, extending over the region of the heart and stomach. The skin,

* Dr. Rehman, in Hufeland's Journ. for June, 1824, or in Edinb. Med. and Surg. Journ., Nos. 82 and 83. In 1828, it re-appeared at Orenburg, and in 1830, advanced through the southern provinces of Russia to Moscow. From Russia it extended

itself into Poland, Germany, Great Britain and Ireland, Holland, France, Portugal, and the New World. Its general course has been, therefore, towards the northwest, with occasional deviations from it.—Ed.

under the nails, became incurvated; the tongue was icy cold; a universal colliquative sweat broke forth, with a shrivelling of the palms of the hands and soles of the feet: the spasms gradually declining as these symptoms increased. In general, all pain and spasm left the patient before death; and even when the heart could not be felt to beat, he expressed himself easy, and said he was better. Sometimes, however, he was, at this period, in the greatest agony, rolling himself on the ground, groaning, and even bellowing most piteously; signs chiefly occurring in patients who lingered three or four days before death came to their relief.

In this description the onset or invasion of the disease is hardly noticed with sufficient minuteness; and I readily supply the deficiency, in this edition, from my friend Mr. Annesley's admirable delineation:—"The patient feels for several hours, or for a greater or shorter period, according to circumstances, a sense of general uneasiness and anxiety about the epigastrium, with a feeling of heat in the same situation. These symptoms increase more or less rapidly; and the countenance, which at first is merely expressive of uneasiness, soon becomes more and more anxious and distressed. The pulse at this time is generally quickened, and always oppressed. This state of the system forms the first stage of the disease; a stage which, from its importance in the treatment, I have called the stage of invasion."* Mr. Annesley's two most prominent symptoms are the sense of heat, or burning pain, as he afterward calls it, in the epigastric region, which is generally felt before the vomiting and purging take place; and the black, thick, and ropy condition of the blood, particularly when the disease is fully formed. He expressly tells us, he never saw a case unaccompanied by the former of these symptoms, while the latter appears to have been as universal;† and I have hence been induced to add both these signs for the first time to its specific character.

[The mind remains clear almost to the last. A favourable issue is denoted by a rising of the

pulse, a return of heat to the surface, an inclination to natural sleep, and a diminution or cessation of vomiting, purging, and spasms; these indications being soon followed by the reappearance of fecal matter in the stools, of bile, of urine, and of saliva. Mr. Scott dwells on the rapid sinking of the pulse as one of the most invariable symptoms; the exceptions being only a few, and chiefly where remedies are promptly administered. In an early stage the pulse generally becomes small and accelerated, and, on the accession of spasm or vomiting, suddenly ceases to be distinguishable in the extremities. The length of time during which a patient will sometimes live in a pulseless state, is extraordinary. Dr. Kellett relates a case where the pulse was gone within three hours from the attack; yet, the man lived in that state from the 3d of October, at four P.M., to the 6th, at two P.M. On the cessation of the spasm or vomiting, and sometimes apparently from the exhibition of remedies, the pulse will return to the extremities for a short time, and again cease. The superficial veins and arteries are not always collapsed, even when the pulse has ceased; and, if opened, they will bleed. Their parietes then collapse, and no more blood can be extracted. In every fatal case, the circulation stops, at least in the extremities, long before death.*]

The following appearances were remarked on dissection: an enormous distention of the stomach and bowels, not from air, but a gelatinous substance; little sanguineous turgescence on the surface of the organs, but an absence of the moisture and glossy character of health: the liver much enlarged from the quantity of blood contained in its vessels, and, on one part of its convex surface, a considerable extravasation of blood: the gall-bladder filled with bile, and projecting beyond the edge of the liver; the bile of a very dark colour, and the gall-ducts pervious. The contents of the small intestines were dark-coloured, apparently from an admixture of bile: the contents of the large intestines resembled the white albuminous matter that was discharged before death.† The urinary bladder was

* Sketches of the most Prevalent Diseases of India, &c. By James Annesley, 8vo. Lond. 1825. The whole of this paragraph, in Dr. Good's handwriting, was lately found among his papers, with a reference to the part of this work in which he intended to have inserted it.—Ed.

† The appearances of the blood in the epidemic cholera of Europe correspond to Mr. Annesley's description of them in relation to the disease in Asia. The blood is observed to be black or dark-coloured, not unlike tar, and in its consistence thick, ropy, and semi-coagulated. It may be doubted, however, whether Dr. Good was correct in altering the definition, so as to embrace these changes in the blood; for, according to the Madras Report, in a few cases they did not occur, though the blood was always deficient in serum, and destitute of the buffy coat. Chymical analysis of the evacuations from the stomach and bowels proves, indeed, that what the blood has been deprived of is to be found in them, inasmuch as the fluid and more copious part of them consists of pure serum, and the coagulated part, or flaky matter, of fibrin.—Ed.

* Scott's Report on the Epidemic Cholera, &c., p. 21-25. Madras, 1821. Professor Cruveilhier knows of some instances, in which the brachial artery was opened, but only a few drops of blood could be procured from it.—Anat. Pathol., livr. 14me. In several cases, the editor has felt the carotids beating forcibly, when no pulsation could be perceived in the arteries of the limbs.

† In a certain number of cases at Paris which proved fatal at the blue period, Cruveilhier found the small intestines distended with an enormous quantity of choleric fluid. When, however, the patient had got through the blue stage, and died sometime after the reaction, none of this liquid was seen in the small intestines, but a yellowish or greenish pulaceous substance, which is compared to the meconium. The follicles were constantly enlarged; every shade of colour, from pink to a reddish black, was seen in different instances in the mucous coat. Frequently, points of ecchymosis were noticed; and when the intestine was of a brownish red colour, and a piece of it was held between the leg and the eye, the most delicate arborescent vascularity was seen. Vascular con-

quite empty and wholly shrunk into the pelvis ; the kidneys apparently diminished ; the lungs so much collapsed as hardly to fill one half of the cavity of the chest : no fluid in the pericardium.

Such were the appearances in the body of a sepoy. In the European subject they were the same, with the two following exceptions : the stomach and intestines were distended with wind, instead of with gelatinous fluid, and hence collapsed upon puncturing them : the veins on the outer surface of both, as well as of the mesocolon, were turgid with blood.

[An excellent description of the appearances on dissection in the cases at Madras was published by Mr. Scott, and it shows that they vary considerably in different examples. No particular alteration is found, he says, in the serous membranes ; but the mucous ones generally exhibit signs of disease. The lungs are not unfrequently found in a natural state, but more commonly they are gorged with black blood, and assume the appearance of liver or spleen. Sometimes, however, they are collapsed, lying in the hollows at the sides of the spine, and leaving the thorax nearly empty. The heart and large vessels are distended, and sometimes even its left cavities are filled with dark blood. In the abdomen, the vessels of the viscera are turgid.*

gestion was almost always most strongly marked near the valve of the cœcum, and diminished in proportion to its greater distance from this point. Frequently, such congestion was restricted to the two or three last feet of the small intestines, though sometimes it was manifest through their entire length. In general, the intensity of the redness was in an inverse ratio to its extent. But, from all the facts which came under Cruveilhier's observation, he concludes, that the morbid appearances are the most constant and important in the great intestines. These bowels are sometimes distended with fluid ; sometimes contracted at intervals, as if encircled with a cord at particular points. The choleric fluid was usually found in the great intestines, characterized by its limpid quality, and flakes of mucus, or its resemblance to rice-water. The genuine fluid of cholera, according to Cruveilhier, is only met with in the body of those who have been rapidly destroyed by the disease, and is not copious, unless the alvine discharges have been suppressed. When the patient has struggled two or three days against the disorder, the choleric fluid is not pure, being frequently of various colours, or, like the mucous secretion, tinged with blood. The follicles of the large intestines, near the valve of the cœcum, are in general much developed, and perforated at their centre, which is indicated by a black point. Frequently they are surrounded by a red areola.—(Cruveilhier, *Anat. Pathol.*, livr. 14me., p. 37.)—Ed.

* The disease, as it presents itself in Europe, agrees with this account. In the *post mortem* examinations at Paris, Cruveilhier noticed that the right cavities of the heart and the left ventricles were distended with a great quantity of blood. The left ventricle was sometimes moderately dilated, but, in other instances, so contracted as not to contain a drop of blood. The large arteries were full of liquid blood, but the small ones contained none at all. The whole of the venous system, and more particularly the veins of the abdominal viscera, were gorged with blood.—(*Anat. Pathol.*, livr. 14me., p. 33.)

According to Mr. Scott, the stomach generally preserves its ordinary volume, sometimes containing greenish or yellow turbid matter. The intestinal tube is sometimes collapsed, but more frequently filled with air, distended into pouches containing whitish, turbid, dark, or green fluid. No fecal or other solid matters are found in the intestines ; but, very commonly, large quantities of the conjee-looking fluid, or of turbid serous matter. The duodenum, and occasionally the jejunum, are loaded with an adherent whitish or greenish mucus ; at other times deprived of their natural mucus, and often quite healthy. Traces of bile in the intestines, or of any substance that has descended from the stomach, are exceedingly rare. Sanguineous congestion, and even active inflammation, Mr. Scott represents as more frequent in the bowels than in the stomach, yet as being often absent. He confirms the account given by other writers of the large quantity of bile in the gall-bladder ; but he adds, that the gall-ducts are about as often constricted and impermeable as in the opposite state. The appearances of the spleen, he says, are so diversified, that they throw no light on the nature of the disease. The vessels of the mesentery are generally very full of blood. In the head, appearances of congestion, and even of extravasation, have been frequently observed, but not uniformly. In one case, the sheath of the spinal marrow was inflamed.*

The essential morbid appearances produced by spasmodic cholera, form yet a subject of inquiry ; for those which sometimes occur and sometimes do not, cannot be regarded in this light.† Perhaps the accumulation of the greater

* In the patients who were victims to the disease at Paris, the spleen was generally small, dense, but more brittle than usual, and with an appearance as if the blood had been pressed out of it. The brain and cerebellum were healthy, but injected with blood as in asphyxia ; sometimes with slight ecchymosis ; there was little serosity in the ventricles, or under the arachnoid membrane. The medulla spinalis was healthy, its different sections being tinged with red points. The semilunar ganglions, the solar plexuses, the ganglions of the great sympathetic nerve, the intervertebral ganglions, the pneumo-gastric nerves, and the whole of the nervous system, appeared to Cruveilhier, in the numerous cases where he examined it, to be perfectly sound ; and he expresses his surprise that Delpsch should have met with traces of inflammation in the semilunar ganglions.—(*Anat. Pathol.*, livr. 14me., p. 38, 39.)

† On this interesting point, the statement of Cruveilhier confirms the truth of the remark in the text. After giving a description of the appearances revealed by dissection, Cruveilhier thus proceeds :—"From what has been explained in relation to the morbid anatomy of cholera, it is manifest that this disease is not one of those of whose nature a complete interpretation can be found in any anatomical lesions ; since, besides the cases in which such lesions are clearly marked, others are met with in which they are slight, doubtful, and even totally absent. If, then, we apply the fundamental axiom in morbid anatomy to cholera, namely, that every organic change that does not constantly attend a disease, cannot be considered as making an essential part of it, the importance of post mor-

part of the blood in the vessels of the viscera, the absence of all solid or fecal matter from the intestines, the suppression of the flow of bile into them, the full state of the gall-bladder, the empty and contracted state of the urinary bladder, and the presence of a gelatinous or turbid serous fluid in the bowels, are the changes most inseparably connected with the worst and fatal forms of the disease.]

The disease proved everywhere more fatal to natives than to Europeans: and, among many of the former, no blood could be drawn from the arm, however urgent the symptoms.

The Bombay accounts differ in only a few particulars: the spasms were sometimes clonic or agitated, instead of being entastic or rigid. "In a large proportion," says Mr. Orton, "there is no appearance of spasm in any part of the system. In many there is no purging; in some, no vomiting; and, in others, neither of these symptoms.* I have already observed that these last were by far the most dangerous cases, and that the patients died under them, often in an hour or two; the nervous power appearing to be exhausted almost instantaneously, like the electric fluid from a Leyden jar. Mr. McCabe, depôt-surgeon at Poonamallee," says the same author, "informs me that he has found the cases which to common observation might appear the most desperate (those which were attended with spasms and retchings of extreme violence) actually among the most tractable: a truly valuable remark, which my own experience fully confirms. Dr. Burrell saved eighty-eight out of ninety of his later cases" (*Bombay Report*, p. 68—80), meaning those of this kind. And in his general description of them he says, "that the retching was constant, and the spasms so violent as to require six men to hold the patient on his cot." On the other hand, nothing can

tem examinations in the study of cholera will seem but limited, and the true characters of it must be looked for elsewhere."—*Anat. Pathol.*, livr. 14me., p. 40.) Dr. Brown, after detailing what was remarked in the dissections at Sunderland, expresses his conviction, that the symptoms during life throw much more light on the nature of the disease, and its appropriate treatment, than appearances after death.—(*Cyclop. of Pract. Med.*) In Europe, the bodies of those destroyed by cholera putrefy slowly, as is always the case with subjects which have been deprived of considerable quantities of blood. On the other hand, the alimentary canal putrefies rapidly, as happens in all cases of considerable sanguineous congestion of the digestive organs.—(*Cruveilhier*, op. cit., p. 35.)

* In Europe the disease exhibits similar varieties: thus, with respect to the cases which occurred at Paris, Cruveilhier informs us, that the most constant symptoms were thirst, pain in the epigastrium, vast alteration of the features, with the eyes shut and retracted, small pulse, enfeebled voice, suppression of urine, and disposition to coldness. On the contrary, in some cases, *evacuations from the bowels, vomiting, and cramps*, did not take place. The absence of evacuations from the bowels, however, was a rare circumstance, and also an unfavourable one, as denoting not a stoppage of the flux, but merely an interruption of the excretion of the matters secreted.—(*Anat. Pathol.*, livr. 14me., p. 11.)—Ed.

be more evident than the intractable and fatal nature of those cases, in which the pulse, instead of rising, sinks at once; in which there are no spasms, and scarcely any vomiting or purging; and in which not only the excretion of bile, but of all the secretions, appears to be entirely suspended.—(*Essay on the Epidemic Cholera*, p. 29.) [It is also particularly remarked by Mr. Scott, that, in the low and most dangerous form of cholera, whether in European or native cases, spasm is generally wanting, or is present in a very slight degree.*]

In a few instances, there was even an overflow of yellow bile itself, making an approach to our first species: but these were uniformly of the slightest kind. "The bile," says Mr. Orton, "appears in excess only in the milder cases."—(*Orton's Essay*, p. 71.) And to the same effect Mr. Curtis: "The cases which appeared after this were all of a different nature, much less severe, and none turned out fatal. They were all of them combined with bilious accumulations."—(*Diseases of India*, p. 66.)

The rapid or sudden fatality of the disease in its severest onsets is very singular. Even Sonnerat affirms, "that the patient was frequently carried off in twenty-four hours." But in the later epidemic of 1817 and 1818, this term was wonderfully abridged. "In the second, and very fatal visitation," says Mr. Orton, "of the epidemic experienced by Brigadier-general Pritzler's force, I am informed that vomiting, purging, and spasms were very frequently, in a great measure, if not entirely, absent; all the powers of the system failing at once, and death commonly ensuing in three or four hours from the attack."—(*Essay on the Epidemic Cholera*, p. 41.) Several instances were heard of at Hoobly and other places, of natives being struck with the disease while walking in the open air: and who, having fallen down, retched a little, complained of vertigo, deafness, and blindness, and expired in a few minutes. Mr. Gordon gives a history of many cases of this kind. At Bellary, a tailor was

* Report on the Epidemic Cholera, &c. Madras, 1824. At Paris, the spasms were among the least constant symptoms of cholera, and Cruveilhier assures us that the gravity of the disorder could not be estimated by them. They began in the muscles of the feet, and proceeded more or less rapidly to those of the legs, thighs, arms, abdomen, thorax, and masseters; they were exceedingly painful, occurred at more or less considerable intervals, and persisted, in some instances, to the last moment; while, in others, they ceased with the collapse.—(*Anat. Pathol.*, livr. 14me., p. 12.) In the cholera at New-York, spasms occurred in about three fourths of the cases. They were sometimes late in their appearance. Their violence seemed to be proportioned to the severity of the purging and vomiting; they were greatest in robust, especially intemperate persons, and more marked in males than females. In children they were rare, or slight.—See Paine's Letters on the Cholera Asphyxia, 8vo., New-York, 1832; one of the most unprejudiced and candid works which the editor has read on this subject; and he feels much obliged to Dr. Paine for his kindness in sending him a copy of his valuable observations.

attacked with what was supposed to be cholera, and instantly expired, with his work in his hands, and in the very attitude in which he was sitting.—(*Bombay Reports*, p. 82.)

The dissections in this presidency seem to have shown even a more extensive range of visceral effusion, congestion, and extravasation than those in Bengal. Not a single thoracic or abdominal organ was to be traced unmarked by vascular rupture, or turgescence of black blood, or unstamped with some other morbid appearance: the stomach and liver, however, were chiefly affected, and the urinary bladder was always shrivelled.* The blood, when drawn from the arm, was found to coagulate very loosely, and sometimes not at all (*Orton's Essay*, p. 69): and the arterial and venous blood were of a like purple hue.†

Of the dreadful spread and havoc of this cruel scourge we may form some idea, from the report to the Medical Board at Bombay, by George Ogilvy, Esq., secretary. The population in this district alone is calculated at from 200,000 to 220,000; the total number of ascertained cases amounted to 15,945: giving a proportion of seven and a half per cent. Of these, 1294 had been without medicine or medical aid, and there is reason to believe that every individual of this number perished. Mr. Ogilvy, indeed, expressly asserts that it was not ascertained that any case had recovered in which medicine had not been administered: while it is gratifying to learn, on the other hand, that, among those who had received the advantages of the judicious and active plan concurrently pursued, the proportion of deaths was reduced to 6.6 per cent.; an alarming mortality still, but a marvellous improvement upon the natural course of the disease. In other parts of India, indeed, the deaths, under the same plan of treatment, seem to have been still fewer: for Dr. Burrell, surgeon to the sixty-fifth regiment, at Seroor, out of sixty cases, makes a return of only four deaths; and Mr. Craw, on the same station, asserts, that on an early application for relief, the disease in his opinion "is not fatal in more than one in a hundred cases."‡

* Reports of Dr. Burrell and Mr. Whyte. In the *post mortem* examinations at Paris, the kidneys appeared to Cruveilhier to be in the natural state; but the bladder was as contracted as possible, and completely empty, at least in those subjects which had perished in the stage of asphyxia; for urine is commonly found in the bladder of other individuals, who die in the period of reaction. In the dissections made in France, the liver was gorged with blood, but unequally, which gave the part a morbid appearance.—Ed.

† For the ravage and treatment of this disease in the Madras presidency, see, in addition to Mr. Scott's Report, Sketches of the most prevalent Diseases of India, comprising a Treatise on the Epidemic Cholera, &c. By James Annesley, Esq. Lond. 8vo., 1825.

‡ Further experience has not proved such efficacy in this, or any other mode of treatment hitherto suggested; nor does any method appear to be attended with uniformity in its degree of success in various places. As Dr. Joseph Brown observes, "in taking these estimates into considera-

The curative plan pursued with so much success consisted in bleeding, according to the strength of the patient; calomel in free doses of from fifteen to twenty grains in a dose; with one or two grains of opium, repeated, if necessary, every four, three, and in some cases every two hours, till the urgency of the symptoms abated: to these were added a liberal use of the most diffusible stimuli, as the spirit of nitric ether, ammonia, camphire, hot arrack and water, mixed with spices and sugar, camphire-mixture, essential oil of peppermint, the hot bath, stimulant embrocations; and sometimes the antimonial powder in doses of five grains, given in conjunction with the calomel.

We are informed of a fortunate blunder in one instance, capable of being laid hold of and applied with great practical advantages. "By mistake, twenty grains of calomel and sixty minims of laudanum were given at an interval of less than half an hour. The patient was inclined to sleep; nothing more was done; and, in two hours and a half, he was as well as ever he had been in his life."

Many of the cases proved successful without the use of the lancet: but, according to Dr. Burrell's return, the hazard of omitting it, whenever blood could be made to flow, seems rather unjustifiable; for, out of a hundred patients eighty-eight were bled, and twelve not; of the former, two died, being one to forty-four; of the latter, eight, being two thirds, or nearly thirty to forty-four. The fact appears to be that scarcely any case occurs without an alarming congestion in one or more of the larger organs; and hence it is highly hazardous to depend upon stimulants alone, and to boast of their power to subdue the disease without active evacuations in the beginning of the curative process, as Hufeland, and other writers on the continent, appear to have done (*N. Annales*, i., 404; *Gazette Sanitaire de Bouillon*, 1787); and as Dr. Rankeen of the Bengal station has recommended still more recently, who treats calomel with as much contempt as the lancet, and depends exclusively, from the first, upon large doses of opium, and highly pungent and diffusible stimulants.*

tion, we must always recollect, that, in epidemics, there is often a very wide difference in the gravity of the disease at different points, or in different years; indeed, sometimes at nearly the same point, and in the same year; so that, when we hear of an extremely small loss, in proportion to the number attacked, long experience does not permit us to doubt that, in such a case, the type of the disease has been very mild.—(*Cyclop. of Pract. Med.*, art. CHOLERA).—Ed.

* *Edinb. Med. and Surg. Journ.*, Jan., 1823, and compare with Dr. Robson's History, id., Oct., 1823, p. 507. Had Dr. Good lived to have seen this extraordinary disease, perhaps he would not have been such an advocate for the early use of the lancet. At all events, its advantages are disputed by men of great experience. Dr. Mouat's observations are decidedly against bleeding. Venesection, which was tried in forty-six cases, was of no benefit, and, in several, it was decidedly injurious. The treatment found to answer best consisted of large doses of calomel with opium, magnesia.

Of the remote cause of this extraordinary malady we know nothing. That it is an epidemic, and of a most malignant character, is unquestionable; but whether dependant upon an intemperament of the atmosphere, or upon specific contagion, is by no means ascertained. The first was the most obvious mode of accounting for it, and that which was earliest adopted; but by many practitioners it has been rejected, for the following reasons:—The disease, instead of spreading from a centre to a circumference, or following the course of the wind, or of the sun, or obeying any other meteorological power, marched by a chain of posts, often in direct opposition to all kinds of atmospherical influence, and in the immediate track of human intercourse. "It prevailed," observes Sir Gilbert Blane, in his remarks upon Mr. Corbyn's letter, "to a degree equally violent at all seasons of the year: in regard to temperature, from 40 or 50 degrees of Fahrenheit to 90 or 100: in regard to moisture, during the continuance of almost incessant rain for months, to that dry state of the atmosphere which scarcely leaves a vestige of vegetation on the surface of the earth."—(*Med. Chir. Transact.*) To which I may add, that it often fought its way in the very teeth of the most powerful monsoons, and left untouched various districts that bordered on its career, and whose less salubrious features seemed to invite an acquaintance with it. It appeared also and vanished in all the changes of the moon, and in all states of atmospherical electricity: and at sea as well as at land. Mr. Corbyn, indeed, gives an account of its having made an attack upon the Lascars of an Indianman, in its passage from England to the Cape of Good Hope, in 1814; and that too in the month of January, when the weather was intensely cold.—(*Treatise on the Epidemic.*) [This alleged attack of cholera, however, requires proof of its having been similar to the spasmodic cases in India, where it had not then arisen in its worst and most fatal shapes. It is even asserted by Mr. Scott, that no instance has ever been recorded of the crew of a ship suffering from cholera, that is to say, the real spasmodic cholera, until the vessel had come into communication with the land.—(*Report on the Epidemic Cholera, &c.*, p. 39.) Spasmodic cholera, we know, broke out in the Mauritius, 3000 miles from a place where it was prevailing; but it was after a vessel had arrived from that very place.]

Many pathologists, who suppose the disease to be propagated by a specific contagion, have endeavoured to show that it appeared in no town or district where a direct communication

stimulants, blisters to the epigastrium, bottles of hot water to the sides and feet, and friction with the hand. (See *Trans. of the Med. and Phys. Soc. of Calcutta*, vol. iv., art. 22.) Respecting the practice of bleeding, then, we see much diversity of opinion exists. In the King's Bench, where the editor has had opportunities of seeing the disease, venesection in the early stage of the complaint has generally been abandoned, though sometimes practised in the febrile stage with decided success.—*Ep.*

had not been maintained with some place in which it was prevalent. [They insist on the considerable mortality among the attendants on the sick; a point, however, on which much contrary evidence is adduced, and which perhaps may be generally quite as well explained by the exposure of such individuals to the same atmospheric causes, or other circumstances by which the patients themselves were affected. Yet, some facts in support of contagion are strong: the medical officer, Mr. Scott says, in repeated instances, has been the only European in the corps or station who has suffered. Dr. Daun and Mr. Gray, assistant-surgeon of H. M. 89th regiment, were both seized with the disease, after close intercourse with the sick; and two friends, who attended the latter, were also attacked, while no other European officer of the corps suffered. Another fact, stated by Dr. Kennedy, is, that in the course of the twelvemonth ending June, 1826, four medical officers of the Bombay establishment out of 116 died of cholera, while among the other gentlemen, civil and military, so great a proportion of casualties from cholera did not occur in the whole course of the epidemic from 1817 downwards.* But, in order to show the contradictory evidence brought forward, it is only necessary to mention, that while one reporter states, that every one of the thirty medical attendants of the 65th regiment was attacked, another declares, that only one out of 101 medical attendants of the Royals had the disease.† No doubt, therefore, some important collateral circumstances, adequate to explain this difference, must have existed, though they were not traced and specified. By some reasoners, little importance is attached to the numerous instances recorded, in which the disease, after appearing in a district, has extended itself over it, apparently by communication with the sick. Facts of this kind, as a critical writer observes, are easily explained by the non-contagionists, provided it cannot be shown that the disease spread gradually, and from the original spot of its appearance as a centre, except where a deviation from its regular course was connected with special intercommunication or special seclusion. One of the most striking features of a contagious disease is its progressive advancement from district to district, and from country to country, and more especially the *slowness* with which it advances. He joins Sir Gilbert Blane in the belief, that such a character can only be derived from the mode of propagation being by human intercourse. When viewed in relation to this character, the history of the cholera of

* See Kennedy's Notes on the Epidemic Cholera, 8vo., Calcutta, 1827. This work, and the writings of Sir Gilbert Blane, contain the best exposition of the arguments in support of the doctrine of contagion.

† At St. Petersburg, 25 medical attendants out of 264 were attacked, and nine of them died; yet Drs. Russell and Barry, who communicate these facts, inform us, that in one Military General Hospital, where 400 cases of cholera had been admitted, only one medical practitioner was seized with the disorder.

the east furnishes a very powerful argument in support of its contagious nature. Its slow progress across and down the peninsula, in 1818, can hardly be explained on any principle, except that of propagation by human intercourse. This intercourse, Dr. Kennedy observes, was established by means of the troops; and it seems, that since 1817, it has been enforced from one end of India to the other by the annual relief of troops.—(*Notes on the Epidemic Cholera*, p. 53.) In short, it is argued, that some effectual intercourse must be necessary for the propagation of the disease, on account of the remarkable shortness of its course, and the brief interval which (if it be really propagated by infection or contagion) elapses betwixt exposure and seizure. The two characters will not interfere with the rapidity of diffusion of a contagious disease over a town, or thickly-peopled district; but must render nearly harmless all ordinary communication between one district and another even moderately remote. The cholera spreads rapidly in a particular spot, but slowly from one part of the country to another. But by far the most unequivocal evidence of the propagation of a disease by intercourse with the sick, is that which is enforced by Dr. Alison; namely, the evidence of the disease breaking out in several previously unaffected districts, at a time corresponding with the arrival in them and sickening of persons who had intercourse with the sick in an infected district. It is to this criterion chiefly that we must look for the decision of the question of the contagiousness both of cholera and other diseases, whose propagation by intercourse is at present a subject of dispute.* It has been asserted by the believers in the propagation of cholera by contagion alone, that the disease has always been found to move in the line of human intercourse; but, though this seems to be the case, its diffusion has not been in proportion to the intercourse between infected and healthy districts. Thus, as Dr. J. Brown has noticed, its appearance at Madras, whither, according to the exclusive doctrine of contagion, it ought to have been conveyed almost three months earlier, by trading vessels from the infected districts, was simultaneous, as Mr. Bell informs us, with its origin in parallel latitudes in the interior. It did not reach Ceylon, to which, on the contagious principle, it ought to have been conveyed at a much earlier period, by shipping from infected parts of the coast, until it had previously gained the nearest point to it on the continent, about Adam's Bridge, and had been long prevailing on both coasts of the peninsula.

* See Edinb. Med. Journal, No. 93, p. 426—431. As an illustration, the breaking out of the disease at Jaulnah may be referred to, after the arrival of a party of troops there from Nagpore, in which place the disease was then raging. From Jaulnah it next extended itself to Malligaum and Hydrabad.—(*Madras Report*.) In several fortresses in the territory of Orenburg, also, the invasion of the epidemic coincided in point of time with the arrival in them and sickening of persons coming from infected places.—(*Lichtenstadt on the Asiatic Cholera*, as it appeared in Russia in 1829—30. Vide Edinb. Med. and Surg. Journ., No. 108.)

—(*Orton on Cholera*, 2d ed., p. 332.) Unfrequented villages have been observed to suffer the invasion of the disease, as early as the marts of intercourse and commerce. Thus, from a statement of Mr. Orton, it seems to have reached some villages on the north bank of the Cavery, detached from any frequented road, and considerably to the eastward of Trichinopoly, quite as soon as this large and frequented town, whither it appeared to have been imported by a company of sepoys.

"Its movement along navigable rivers has been dwelt upon, as evidence that human intercourse has been the means of its diffusion; but when we are informed, by Mr. Orton, that the disease manifested this predilection for the course of rivers in the peninsula of Hindostan, where navigation is scarcely carried on, even to the most trifling extent, on any river, and scarcely an instance can be mentioned of any great road running on the banks of a river, for they almost always cross them, we must acknowledge that more weight has been attached to the argument than it is calculated to bear.

"The disease, in its general course, has manifested a preference for one line of movement, and has rejected another, though there has been no striking difference in the amount of human intercourse between the two directions to explain the preference and rejection. Its progress in a northwestern direction, across the European continent, has been briefly described," &c.

For three years it prevailed in the Ottoman territories bordering on the Levant, without losing any of its destructive character; for in November, 1832, it carried off in Aleppo 4000 victims in eighteen days; yet, as Dr. Brown has observed, it did not penetrate into Turkey in Europe, and other extensive realms on the shores of the Mediterranean. "Assuredly," says he, "this could not arise from want of means of transport, and few will be disposed to ascribe it to the perfection of the quarantine department of the Sublime Porte." Since its appearance in Great Britain, "a similar predilection has been displayed: for we find it at this instant 140 miles to the N. W. of Sunderland, while six miles south is the extreme distance to which it has reached in that direction; and from the point which it attained, Seaham Harbour, after attacking eight persons, and destroying three, it has since vanished."—(*Cyclop. of Pract. Med.*) Dr. Brown is led to the conclusion that the disease possesses a contagious property, though in so feeble a degree as to render it more than questionable whether it can be the sole agent in diffusing the disease. That endemic influences prevail, was convincingly illustrated in Sunderland, where the disorder committed infinitely the greatest ravages in dirty parts of the town, situated low, and near the banks of the river. In the village of Newburn, the whole of which is thus conditioned, 120 persons, of whom 55 perished, had been attacked out of a population of 550, and the disease had not yet ceased.]

Certainly it is not easy to reconcile the suddenness of its appearance and disappearance with the laws of contagion, so far as we are ac-

quainted with them; a subject we shall have occasion to examine at large, when treating of fevers. Mr. Allardyce informs us, that in the 34th regiment the disease appeared on the 21st of September, and committed dreadful ravages before night. On the 25th it abated remarkably, and in three days more entirely vanished.—(*Reports communicated to the Bombay Medical Board.*) In like manner, the severe attack which was experienced by the Bengal and Madras troops at Nagpore, occurred at the end of May, 1818. On the 10th of June the rains appeared with great violence, when the epidemic abated, and immediately afterward ceased.* Neither is the idea of a contagious propagation reconcileable with the escape of the great body of persons exposed to the influence of the disease, considering that, from its not being apprehended to be contagious, no means, as is usual in other cases, were employed to avoid the infection.

The state of the atmosphere, as described by Mr. Allardyce, did not differ materially from that in Nagpore. The disease made its attack in close and sultry weather, and vanished after thunder-storms and heavy rains. But we can draw no conclusions from these phenomena; since it seems to have shown itself quite as frequently and fatally after a long succession of rain; and as already observed, sometimes in very cold and dry weather. The remote cause, therefore, of this mysterious scourge, remains yet to be ascertained; and affords further proof, if indeed proof were wanting, of our general unacquaintance with the nature and economy of epidemics.†

* "The gradual diffusion of a disease through a limited community, those near the sick being first attacked, and others in succession, in proportion to their proximity, Dr. Joseph Brown admits, is strong evidence of a disease being contagious. But this evidence, he observes, has rarely been furnished by the cholera; the general statement from India, indeed, is of a totally opposite nature; for we learn that on its appearance in any place, numbers are simultaneously attacked, and that after committing unheard-of ravages for a short period, its cessation is as sudden as its invasion. One example, however, of this gradual diffusion is given in the Russian Reports, and this is furnished by Dr. Schimanski, with regard to the extension of the disease at Iletsk. He says he was able to trace the progress of the disease in the first eight cases thus: the husband of the woman (a soldier's wife), from Orenburg, was taken ill three days after her; and about the same time also, two girls, who lived in the immediate neighbourhood of the soldier, and who visited him soon after his arrival from Orenburg; the aunt of these girls, who nursed him, was next attacked, and from her it passed to her own two sons."—See Dr. Brown's article in the *Cyclop. of Pract. Medicine*, and the *Edinb. Med. and Surg. Jour.*, No. 108.—Ed.

† Various facts, mentioned by Dr. Haslewood, support the doctrine of spasmodic cholera being a contagious disease.—(See *Med. Gazette*, vol. x.) Dr. Elliotson has a strong suspicion that the disease is contagious; but believes that it may also spread independently of contagion (*Lect.*, &c.), and this is the view which is entertained by many others, among whom is Dr. J. Brown. Individ-

With the exception of the plague, there is no epidemic on record that seems to have been so strikingly marked by violence and irregularity of action, and especially by a rapid exhaustion of living power; the patient, as we have seen, often expiring within twelve hours from the attack, and sometimes sooner.

The first characteristic feature that occurs to us, on a review of the disease, is the total absence of the bile from the whole range of the alimentary canal in every case, while this fluid was as generally found in abundance in the gall-bladder: and perhaps the next is, the turgid, and in some instances, the ruptured state of the liver, from the quantity of blood with which it was distended. The general battery of symptoms appears, therefore, to have been opened by a spasmodic constriction of the bile-ducts; for without such an obstruction, we cannot account for an exclusion of all bile from the intestines. From this point, as from a centre, the spasmodic

uals in good health, and at the same time in good circumstances, are much less liable to be attacked than individuals labouring under the noxious effects of poverty, intemperance, or debility from previous illness, for which two last conditions, it is scarcely necessary to say, affluence will be no counterbalancing protection. A very large proportion of the individuals carried off by this disease in London are known to have been habitual spirit-drinkers. Undoubtedly, exceptions to this statement frequently occur, reminding us of our ignorance of the particular influences which sometimes render thousands susceptible of the disease, though greater numbers, equally exposed to the contagion, if it be such, seem to defy its power. To every mind it would not be satisfactory to attempt to solve the difficulty by reference to the fact, that persons in health are not easily attacked, because when spasmodic cholera suddenly carries off hundreds and thousands in a particular district, town, or division of an army, it is not to be imagined that all these unfortunate subjects had really been in previous bad health. Here denial influence must be supposed to be in operation. The first case of spasmodic cholera which ever occurred could not possibly have arisen from contagion, but from some atmospheric or terrestrial causes affecting the unfortunate individual the first subject of it. The history of the disease seems to prove that the extension of it is partly, at all events, owing to the same influences. Thus, the disorder may have had many distinct origins in different individuals and parts of the world. In support of this argument the following is a strong case. When the disease attacked the 6th regiment at Colabah, in July, 1828, it was in the midst of the rainy season, when not a case had been seen for months either in or near Bombay. Mr. Campbell, in paying his evening visit to the hospital, found an old soldier, who had been under treatment some time for an hepatic affection, suddenly seized with cholera. Mr. Campbell went to the opposite extremity of the building for the purpose of consulting another surgeon, and actually found him busily employed with another man, who had been almost simultaneously affected. The disease proceeded, and destroyed sixty men and several women.—(*Spence in Med. Gazette.*) The fact of cholera having broken out at Vienna, when Austria had numerous *cordons sanitaires* on the side of Hungary, is often quoted by those who, like Cruveilhier, deny its contagious nature.—Ed.

action seems to have spread in every direction, and under a clonic or entastic form, to have seized upon almost every organ: preying with greater violence according to the greater degree of debility, and hence, perhaps, of irritability of the system; into which law we are to resolve it, that the natives, supported by a less rich and nutritive diet than the Europeans, suffered more severely, and died more frequently. The stomach and intestines, generally speaking, first participated in the spasm of the bile-canals, and hence the griping pains, the nausea, and violent commotions which spread from the one to the other.

In all cases of nausea, from whatever cause, we see the brain and the surface of the body peculiarly diminished in their energy, whence the skin, to the remotest extremities, collapses beneath a deadly chill, and the heart sinks with insupportable languor. In the ordinary course of sickness the nausea subsides, and the general organization recovers its balance, or it terminates in full vomiting, which excites a universal reaction. And where any such reaction occurred in the disease before us, it was hailed as a favourable change; and hence the wisdom of the stimulant plan, so frequently had recourse to by the medical staff, for the purpose of producing a revulsion. But where this was not accomplished, the living power, feebly recruited from its fountain from the first, or not recruited at all, became exhausted in every organ apace, the strength failed, and hope gave way to despair.*

* Searle, Stevens, Desruelle, and others, believe that the poison of cholera (supposing such to exist) is introduced into the circulation, and combined with the blood, through the medium of which it produces its effects on the solids of the body, and not by any direct impression on the nervous system. Other pathologists represent cholera as making its first impression on the nervous system, either without limitation, or with the restriction of such impression to the central ganglionic system. These views are rejected by others; thus, Dr. Paine concludes that the brain and nerves are not the primary seat of cholera, and that they subsequently participate less than some other organs in the morbid action; he allows, however, that they may serve to transmit the impression from the morbid agent to other parts of the system; and this is, perhaps, as much as the advocates of the hypothesis mean to assert. "If we look at the mind," says this intelligent physician, "we shall find it 'sitting unimpaired and serene amid the ruins of organic life.' Respiration is only performed by the voluntary muscles; pulsation has long ceased in the extremities; the heart has become inaudible to the stethoscope; yet the integrity of the mind remains undisturbed; and the indifference with which it contemplates the wreck over which it presides, proves, that at least its peculiar and last abode in the body is still its own uninvaded possession. The powers of the mind are fully exercised in respect to the voluntary muscles; and it is not unusual to witness successful attempts at walking, when the pulsations of the heart are only sensible to the ear." While the functions of the brain are wholly undisturbed, "the heart and the lungs, and all the viscera of organic life, are involved in a chaos of disordered action. Animal sensibility is not known to be

In the Island of Ceylon, where the disease raged with even more violence than on the Indian continent, the patient very frequently expired in twelve or fifteen hours from its attack. The dissection of those who perished thus early in this quarter, has put us into possession of some interesting facts, varying in a few particulars from those that occurred on post-obit examinations in the Island of Bombay. The brain was in these cases chiefly the congested organ, the liver sometimes appearing to have no congestion whatever; and hence the inactivity produced in the brain by the nauseating state of the stomach, must have been greatly augmented by oppression. Consentaneous herewith we are told by Dr. Davy, that in some of the cases which he dissected in this region, there was a flaccidity of all the muscular parts,* as in animals killed by electricity or hunted to death. There was also a tenderness of the muscular fibres; while antecedently to death, as in many of the Bombay cases, there was no difference in the colour of the arterial and venous blood, and no instance of a buffy coat on the blood that was drawn; which in reality was so loose and uncoagulable, that when venesection was necessary, the vessels were opened with the greatest caution, from the difficulty of restraining the blood afterward.

In certain cases, the muscles of the extrem-

particularly affected till near the termination of life. It is scarcely augmented or diminished, or in any way modified,—a remarkable circumstance, if we regard the common influence of disease on that property, and which serves to demonstrate the little participation of the nervous system in the great conflict of nature. The sufferer is even conscious of the unequal distribution of heat, and feels, as intensely as if in health, the action of stimulants upon the cold, and shrivelled, and livid surface of his body. He hears and sees with a natural acuteness." Such facts, Dr. Paine conceives, render the hypothesis of diminished nervous energy quite paradoxical. His particular notion is, that "the proximate cause of cholera asphyxia consists in a simultaneous modification of all the organic powers and functions, produced by some unknown morbid poison, acting either directly on the properties (of the body?), or transmitted indirectly through the nervous system." If, says he, we assume a local proximate cause, we should always be able to detect its existence; but "we have now been presented in New-York with many cases in which the invasion of the most malignant constitutional symptoms was abrupt, and in which there could not be detected a solitary evidence of antecedent local disease."—See Paine's *Letters on Cholera Asphyxia*, p. 71-77, 8vo. New-York, 1832. The rest of Dr. Paine's argument on this part of the subject is instructive, even without admitting his own particular hypothesis; for he has ably exposed a variety of erroneous views, and this, at all events, is clearing the way to truth.—Ed.

* In Europe this is not generally the case; thus, at Paris, the muscles were found by Cruveilhier to be in such a state of rigidity, that he compares their appearance to what is seen in the bodies of persons executed.—(Anat. Pathol., livr. 14me, p. 35.) At New-York, the muscles were also observed to be very rigid in the dead body.—(Paine's *Letters on Cholera Asphyxia*, p. 147.) They are likewise of a very florid colour.—Ed.

ities, and even of the face and lower jaw, were observed to move in a convulsive manner and sometimes to be drawn into tremulous knots, fifteen or even twenty minutes after death had closed the scene. So the heart of the traitor, when extirpated after he has been beheaded, from an accumulation of sensorial power, has been seen to palpitate, and even to leap up for several times in succession, after its removal from the pericardium.

Commonly, however, the living principle seems to have been exhausted more generally and progressively; and the muscles, and indeed most of the organs, freed from the tetanic power that at first constricted them, to have been gradually relaxed and flaccid: and hence that comparative absence of pain that occurred so frequently a short time before death, with a flow of a cold sweat over the surface of the body, and of bile into the smaller intestines.*

The grand objects, in the treatment recommended by the medical boards in India, were to equalize the distribution of the blood and nervous influence, to counteract the spastic action so common to the irritable diathesis of hot countries, to guard against the danger of congestion in the vital organs, and to restore the natural secretions of the system. The great danger of congestion was guarded against by bleeding; spasm and irritability were opposed by powerful narcotics; and the full and repeated doses of calomel were admirably calculated to act upon the secretants, and restore them to their proper functions, and especially when united, as was occasionally the case, and, perhaps, always ought to have been, with antimonials. All this was sometimes accomplished rapidly, and the disease ceased in a few hours. But if, from the violence of the attack, or from any other cause, it could not be accomplished at all, such violence could not long be resisted; and the patient in a few hours, or at the utmost in two or three days, fell a prey to its fury.

Sir James McGrigor has informed me, that the disease in the Mauritius did not appear till after the arrival of a ship on its coast from Ceylon, where the epidemic was raging; some of the crew of which were seized with it on their passage, though all were well at the time of sailing. As a single fact, this is not sufficient to prove contagion; but, in the present uncertainty of the subject, the statement is worth treasuring in mind.

[Another fact, bearing on the same question, and tending to support the doctrine of contagion, is, that the disease does not appear to have reached the shores of the Persian Gulf by land;

* Some writers impute the effect of spasmodic cholera to the absence of bile; yet abundance of this fluid is in the gall-bladder, and even after the reaction, when bile has found its way into the stomach and bowels, this circumstance frequently does not prevent a fatal termination.—(Cruveilhier, *livr. 14me.*, p. 41.) This eminent pathologist inclines to the doctrine, that the disease essentially consists in an affection of the secreting function of the gastro-intestinal mucous membrane. He is led to this conclusion by the quality and quantity of the fluid voided from the bowels.—Ed.

but broke out in the seaports and trading towns, immediately after the arrival of ships from Bombay. It soon afterward raged in Schiraz, and its extension to Ispahan was greatly apprehended; but the latter city was preserved from it, as is alleged, by the governor-general prohibiting the caravans of Schiraz from passing through the place.—(*Dr. Rehman, in Hufeland's Journal for June, 1824.*)]

Mr. Cornish, in a communication dated Tabriz, in Persia, October, 1822, announcing the arrival of this fearful disease on the western boundary of the Persian empire, expresses his belief that it is an epidemic not dependant on contagion, and then adds the following alarming prediction: "The atmosphere is generally clear, cold, and healthy; and if, in such a climate, this epidemic commits such ravages as almost to equal its effects in many parts of India, I much fear it will extend to Europe, where the crowded cities and great population will make it more severely felt than it has been in the scattered cities and scanty population of Persia."—(*Medico-Chir. Trans.*, vol. xii.)

"Dii, prohibete minas! Dii, talem avertite casum!"

[Unhappily, Mr. Cornish's prediction has proved but too true, and the identity of the disease in Hindostan, Europe, and America, admits of no rational dispute. Its nature is everywhere the same, though subject to modifications, more especially in relation to its fatality, which has been much greater in certain places and in the invasions of particular periods than in others.

The Bengal Report adverts to a fever which attended the second stage of the disease. Now this consecutive fever is stated by Dr. Russell and Sir David Barry to have been more frequent in Russia than in India; that is to say, the direct restoration to health from the cold stage, without the intervention of such fever, was more common in India than at St. Petersburg. Among other points of difference between the cholera of India and that of Europe, they specify the following:—"The evacuations, both upwards and downwards, seem to have been much more profuse and ungovernable in the Indian than the European cholera, though the quality of the evacuations is in both cases the same. In India the proportion of deaths in the cold stage, compared with those in the hot, was far greater. Then the number of medical practitioners and hospital attendants attacked with cholera, in proportion to the whole number employed, and the other classes of society, is stated to have been, beyond all comparison, greater in Europe than India.—(See the *Report of Drs. Russell and Barry to C. C. Greville, Esq.*)

Dr. Brown's definition of epidemic cholera, as it presents itself in England, is perhaps as correct as any that has been suggested:—"After watery diarrhœa, or other generally slight indisposition, vomiting and purging of a white or colourless fluid, violent cramps, great prostration and collapse, the last occurring simultaneously with the vomiting and cramps, or shortly after them. Should the patient survive

the last train of symptoms, a state of excitement and fever supervenes.”—(Dr. Brown, in *Cyclop. of Pract. Medicine*.) By *collapse*, Dr. Brown particularly signifies the feebleness or almost the arrest of the circulation; the death-like appearance, the coldness, shrinking, and occasional blueness of the surface, which may be observed in other diseases, after they have existed some time, but which occur in the cold stage of the epidemic shortly after its commencement. The *degree* and *early accession* of this *collapse*, and the *white discharge*, seem to Dr. Brown the only distinctive marks between this stage of the epidemic and ordinary cholera.

Cruveilhier arranges all the complaints pertaining to epidemic cholera under three heads:—1. Choleric purging, with slight cholera. 2. The state, or degree, between this and the worst forms of the disease, he terms *cholera moyen*. 3. Lastly, malignant cholera (*cholera très-grave*), with or without asphyxia. By *choleric purging*, he means that in which the evacuations are liquid, colourless, with little or no smell, and an appearance like that of turbid whey, or rice-water. The transition from a choleric purging into cholera, is denoted by vomitings, painful spasms in the limbs, urgent thirst, severe pain about the epigastrium, sudden change of the countenance, a sinking of the eyes into the orbits, feebleness of the voice, tendency to coldness, and depression of the pulse.—(*Anat. Pathol.*, livr. 14me., pp. 1-11.)

A better division is into the *incipient*, the *cold*, and the *febrile stages*. All men of experience agree, that most of the cases seen in this country are preceded by some kind of indisposition, as lassitude, vertigo, sense of nausea, oppression about the stomach, or a sense of indescribable uneasiness in it, which ailments are immediately followed by a degree of diarrhoea. Such are the *premonitory symptoms*, as they are called, in which a looseness of the bowels is generally one of the principal circumstances. This looseness, frequently accompanied by tenesmus and colic, when very profuse, brings on, almost immediately, considerable emaciation, complete prostration of strength, feebleness of the voice, a tendency to coldness, and slight cramps. Writers also coincide on another important fact, which is, that when such diarrhoea is rightly treated in its early stage, the accession of cholera may commonly be prevented.* Varieties occur, however, in the mode of attack; for while in the greater number of instances, a diarrhoea precedes the commencement of this species of cholera, in other patients, the complaint comes on without any kind of warning, frequently in the middle of the night, or a little before daybreak,† although the

individuals were perfectly well at the time of going to bed. They awake with severe pain about the stomach, and are soon seized with vomiting and purging, the discharges being at first tinged with bile, but soon becoming colourless and serous, or assuming the appearance of a turbid whitish fluid, like rice-water, with white flakes in it. The evacuations from the bowels are so copious that they are rapidly followed by extreme debility, and, even before any vomiting and cramps take place, they sometimes bring on a collapse, especially in elderly subjects, or individuals whose constitutions are already impaired by intemperance or recent illness.* In some few instances, there is not a single evacuation from the bowels; yet the large intestines are found after death completely distended with the fluid characteristic of the disease. Thus is ushered in the *cold stage*, so called from the remarkable tendency which the body has to become exceedingly cold; it is, indeed, of an icy coldness, or, as Cruveilhier expresses himself, the coldness is like that of death itself. Even the tongue and breath, as it issues from the mouth, are cold. Dr. Elliotson, on passing a thermometer into the mouth, found it to range from 84 to 90 degrees. Cramps, attended with a severe degree of suffering, begin with the vomiting, or even precede it; the pulse becomes frequent, and extremely feeble; the respiration hurried, sometimes 36 in a minute,† the features shrink, the eyes sink into the orbits, and the countenance, which is of course wonderfully changed, is either livid, or very pale.

The first cholera patient whom the editor saw was in the cholera hospital near Bethlehem, and though only 22 years of age, his face would have warranted the conjecture of his being at least sixty. This person had not been ill more than twelve hours. The *facies cholericæ* is so characteristic, that Cruveilhier represents it as being in general sufficient to establish the diagnosis. The eyes sunk in the orbits; the dirty leaden hue of the countenance, when it is not livid; the tendency to blueness of the lips and cheeks; the hideous retraction of all the features; the emaciation, of truly astonishing rapidity, and only partly accounted for by the profuse evacuations from the stomach and bowels, are common appearances in cholera.—(Op. cit., p. 12.)

After a time the vomiting and spasms either the majority of cases; and the next period most common is in the morning, and the next in the afternoon.”—Paine's Let. on Chol. Asphyxia, p. 84.

* See case by Cruveilhier in *Anat. Pathol.*, livr. 14me., p. 21. This author met with several cases in which the stools consisted of blood and mucus, and the patient was removed by tenesmus: in some of these instances the post-mortem examination detected precisely the same anatomical lesions as in dysentery.—(Op. cit., p. 18.)

† Respiration varies in different examples: it may be natural or hurried; in other instances, slow and sighing, but always incomplete; not reviving the blood, as Cruveilhier expresses himself; a defect which he refers less to any impairment of the mechanical part of respiration, than to some injury of its vital phenomena.—(*Anat. Pathol.*, p. 13.)

* The same interesting circumstance was noticed at Paris:—“Je n'ai pas vu un seul deuoement cholérique, convénablement traité dès le moment de l'invasion, qui ait dégénéré en choléra.”—Cruveilhier.

† “It has long been remarked in other countries, that the cholera makes its attack in the night, and particularly towards the approach of day. I think it has so happened in New-York, in

totally subside, or recur at lengthened intervals. The pulse, which has been becoming smaller, and more and more accelerated, at length ceases entirely in the extremities, though the beating of the heart, and sometimes of the carotids, may still be perceptible. Severe pain in the epigastric region is one of the most constant symptoms: when the patient is asked what is the matter with him, he places his hand upon his stomach, or the sternum, and complains of vast oppression, dejection, and sometimes of burning pain in that organ. Many of Cruveilhier's patients said to him, "Remove what I suffer there, and I shall get well."—(Op. cit., p. 12.) If the disease be accompanied by blueness, which is not invariably the case, various shades of this colour occur on the hands and feet, and frequently also on a considerable portion of the arms and legs; indeed, the whole body has been known to exhibit a blue appearance. The hands are shrivelled, corrugated, and soddened, and the fingers often drawn together. The patient is tormented with ardent thirst, and has an insatiable desire for cold beverages. The voice is surprisingly altered; it is like that of a person dying of strangled hernia, and characterized by mingled huskiness and feebleness. Not only is there a stoppage of the flow of bile into the intestinal canal; the urine, in severe cases of cholera, is not secreted during the collapse, and consequently the bladder is empty. When the disease has advanced to its final stage, the patient is like a corpse; the eyes, partly open, shrivel up, either from the absorption of their humours, or from a mechanical transudation of them; the sclerotics, just under the cornea, becomes as dry as parchment, that is to say, immediately above the margin of the lower eyelid, and where it is exposed to the air; the patient is absolutely motionless, and seems to be connected with life merely by a little circulation, and a little respiration, the mechanical part of which still goes on, though without any beneficial effect on the blood. Even the tonicity of the skin seems to be quite destroyed, so that when pinched it remains in a fold, just as it does in the dead body; yet the sensations continue, and the patient usually hears very well; nay, when a sudden paroxysm of epigastric pain attacks him, when cramps come on, or he has an urgent desire to go to stool, he will move with violence, and jump out of bed with a degree of vigour that often astonishes the attendants.*

Sometimes, a little previously to dissolution, the temperature of the skin rises, and after death the body becomes warm, and, what is worthy of remark, has been known to continue so for a space of time never observed after death from any ordinary diseases.† In some examples, long

after all vitality had apparently ceased, twitches and quiverings of the muscles occurred; thus Dr. Elliotson, in speaking of a case which fell under his notice, informs us that one finger would be drawn in, and then another; the lower jaw would move up and down, and a quivering of the muscles of the thigh might be observed. The same occurrences, we find, were noticed in India.

Mr. Rumsey, of Beaconsfield, has recorded an instance in which the action of the muscles was very surprising. About half an hour after the patient's death, *i. e.* "the perfect termination of respiration and circulation, a friend observed his left arm to move, and very soon it obeyed the contractile and relaxing powers of its muscles, slowly, but unceasingly, for about twenty minutes; it then ceased, and the right arm soon made an extensive motion, which threw the by-standers into a panic. Contraction and relaxation, or a moving backwards and forwards, continued, perhaps, to the end of an hour and a quarter. At this moment the arms, previously cold, had become evidently warmer."*

The condition which nearly resembles death, may last several hours, or even one, two, or three days, but rarely longer. It commonly terminates fatally, though this is not invariably the case; and at Paris, Cruveilhier saw several cholera patients restored to life by a kind of resurrection, after lying a whole day, and for a greater period, in the most desperate state.—(Op. cit., p. 19.)

A considerable number of patients never rally from the collapse at all, but perish without any reaction taking place in the system. The lungs may be filled with oxygen gas, the stomach may have the most powerful stimulants introduced into it, and the bowels have the most irritating clysters injected into them; yet, without any more effect than if the mucous surface of each of these organs were completely insensible, and destitute of all influence on the economy. Under these circumstances the disease has only two stages, *the incipient and that of collapse*; but if the patient get over the latter, he is not yet out of danger,—for the reaction which ensues becomes a *febrile stage*, often leading to a fatal termination.† The transition from the collapse

remark:—"The coldness of the skin," he says, "is less intense in the corpse than the living subject;" a circumstance in a great measure owing to the absence of that clammy perspiration which inundates the skin in the last stage of cholera. Mr. Rumsey, of Beaconsfield, accounts for the fact on a similar principle.—See *Med. Gazette* for Sept., 1833, p. 836. In several subjects the warmth of the trunk maintained itself at the end of eighteen hours very much like what happens in asphyxia.—(Op. cit., p. 35.)

* *Med. Gazette* for 1832-33, p. 836. On September 23, 1833, a man died of cholera in the Fleet Prison, without any reaction having taken place. Nearly an hour after the breathing and circulation had ceased, his fingers began to move; then the lower jaw; and on the sternum being pressed upon, the right forearm was suddenly thrown across the breast. The muscular movements lasted twenty minutes.—*Ed.*

* Cruveilhier, op. cit., p. 19. In the first patient the editor ever saw with this disease, these circumstances were very forcibly exemplified. He had no pulse; he was blue nearly from head to foot; and, though only twenty-two, he looked like the remains of a person of sixty; yet he tried to get up half an hour before he died.

† On this subject, Cruveilhier makes a curious

† Speaking of the febrile stage, or the reaction,

to the febrile stage is for the most part very gradual ; perhaps, after the skin has been of an icy coldness for twenty-four or forty-eight hours, or some other uncertain period, a trivial rise in its temperature commences, and the pulse begins to be distinguishable at the wrist again, generally beating about 80, and soft. The patient, on being roused, is perfectly sensible, and complains of severe pain in the head, and giddiness, and that the light distresses his eyes. "The tongue, in this early stage, is clean and moist, the bowels are readily acted upon by medicine, and the discharges are feculent, and, though somewhat clayey, contain a proportion of bile ; but the urinary secretion is sometimes either not restored, or is considerably deficient for a day or two after the establishment of the fever. In the progress of the fever the tongue becomes black, and sordes accumulate about the teeth ; the eyes become more and more injected ; the intellect more and more torpid ; the urinary secretion now returns, and the urine, which was at first dark-coloured and cloudy, is now limpid and pale ; and the alvine discharges are darker than at first. However flushed the countenance may appear, the temperature of the surface is below the healthy standard, and the pulse is seldom above 90. It differs from typhus, not only in the deficiency of calorific power, but in the absence of subsultus and muttering delirium ; for though delirium sometimes occurs in the night, the condition of the intellect is generally rather one of torpor than of irregularity." The duration of the febrile stage corresponding to this description, is from a week to ten days, and the end often fatal. Dr. Brown considers the brain as the organ principally affected in it, and regulates the treatment accordingly, without neglecting, however, the state of the intestinal canal. In another form, consequent to a less formidable state of collapse than what precedes the symptoms above enumerated, the surface of the body is of a higher temperature, and the pulse stronger and more frequent. Depletion could be more freely practised, and the disease was more tractable. But, according to Dr. Brown's experience, the mildest and most successfully treated variety of the febrile stage was attended with pain in the epigastric region on pressure, headache, and giddiness ; the tongue being either clean, with a disposition to become dry and glazed, or slightly white and furred, the skin warm, the pulse free and forcible, the urine high-coloured, the thirst considerable, little or no confusion of ideas, and the eyes not injected. A febrile stage, answering to this type, was observed to follow cases in which the collapse had been inconsiderable, and the urinary secretion not suspended, and in which the disorder had not always been attended with vomiting.

The degree of danger seems to be considerably influenced by the degree of collapse in the

as it is commonly called, Cruveilhier pronounces it to be a period replete with danger ; because "the equilibrium must be re-established, and the determination to the intestinal canal must cease gradually, and not be converted into acute or chronic inflammation."—(Op. cit., p. 29.)

cold stage ; and it is well observed by Dr. Brown, whether we are to dread a fatal result in the cold or the excited stage, the intensity and duration of the collapse in the former of these stages are the measure of the danger ; for if the patient die in this stage, he dies of collapse ; and if he survive it, and pass into the state of fever, the character of this fever is dangerous in proportion to the same collapse.*

At Paris, numerous patients, presumed to be convalescent, afterward died in a comatose state ; and yet, on opening their bodies, scarcely any vestiges of cerebral congestion were found—hardly any serosity under the arachnoid membrane, or in the ventricles. Many of these unfortunate terminations Cruveilhier ascribes to the immoderate use of opium in the stage of asphyxia ; and he particularly cautions us to recollect, that though the animal economy in this deathlike condition is insensible to the most powerful medicines, no sooner does reaction begin, than the system becomes again obedient to the customary laws of life, and acted upon not only by what is now administered, but by what has been previously given.—(Op. cit., p. 32.)

The state of the blood in spasmodic cholera has attracted general attention. Cruveilhier found its properties much the same, both in the dead subject and after venesection. It was characterized by a deficiency of serum, and a consistence very much like that of thick currant jelly. It coagulates imperfectly, and is often compared to tar.

Writers in general impute the loss of serum to the prodigious and rapid abstraction of fluid from the circulation to supply the secretion from the mucous coat of the intestinal canal. In fact, the liquid part of the discharges from the stomach and bowels has all the properties of serum ; while the flakes in it consist of fibrin. It is alleged that the blood taken away from patients in cholera does not assume a scarlet colour ; but Cruveilhier thinks it would have been more correct to say, that it does so only slowly, and not at all, when its surface is dry.—(Op. cit., p. 39.) In the United States, Dr. Gale detected an oily matter peculiar to the blood of patients afflicted with cholera, and different from that described by Lecanu, and discovered by Schwlgué. The former, he says, is obtained by solution of the solids contained in the blood in alcohol ; the latter is found floating on the surface of the blood when taken from the body. The proportions vary with the

* Dr. Brown in *Cyclop. of Pract. Med.*, art. CHOLERA. The depression of the pulse seems to Cruveilhier to be a better criterion of the degree of danger of the disease than any of the other symptoms. "It is," says he, "by the pulse that the reaction begins to show itself, just as it is by the pulse that the collapse (concentration) is denoted. When it is suspended, not for a few moments, but for some considerable time, the danger is imminent."—(Op. cit., p. 13.) Here we see an agreement between the two latter writers ; but Dr. Brown's prognosis, deduced from the degree of collapse, is more clearly explained, more especially with reference to the patient's fate, in the febrile as well as the cold stage.—Ed.

stage of the disease, increasing as it is more advanced.—(*Paine's Letters*, p. 155.) Free acetic acid, regarded by Herrman as a constituent of healthy blood, was ascertained by him to be deficient in the blood of patients labouring under spasmodic cholera.—(See *Med. Chir. Review*, July, 1831, p. 285.) Dr. O'Shaugnessy analyzed the blood of some cholera patients, and not only ascertained that there was a deficiency of water in it, but of its saline ingredients. In two cases, there was a total absence of carbonate of soda. His experiments led him to believe that the saline particles, deficient in the blood, passed away with the alvine discharge; but Dr. Elliotson examined the matter voided from the bowels in several instances where no alkali had been taken, and found it acid (*Med. Gazette*, 1832-3, p. 630); and he does not consider it proved that there is an excess of alkali in the evacuations, as would happen according to the theory suggested by Dr. O'Shaugnessy.

Spasmodic cholera can only be treated in the same unsatisfactory manner as all other diseases whose causes are unknown; and, as Cruveilhier has justly said, we combat merely its effects; just like an unskilful practitioner, who, having to treat a severe ophthalmia, excited by the lodgment of a foreign body on the conjunctiva, attacks the inflammation with the whole series of antiphlogistic means; whereas the simple removal of the foreign body would have been sufficient for the cure.—(*Op. cit.*, p. 45.)

The treatment of cholera spasmodica may be conveniently considered, in relation to the incipient stage, the cold stage, the febrile stage, or period of reaction, and the later consequences of the disease.

The diarrhœa, and other ailments generally preceding cholera, may generally be treated with complete success, if attended to early enough. But on this subject we need say but little, as the discussion would only oblige us to return to the consideration of diarrhœa. Opium is the principal remedy, and when employed early, seldom fails. If there be reason to believe that the looseness is accompanied by chronic enteritis, leeches should be applied to the abdomen.

In the *cold stage of cholera*, or the period of asphyxia, or concentration, as it is sometimes termed, medical practitioners agree very generally about the right indication, which is to rally the constitution by every possible means. The action of the heart and lungs must be promoted; and the whole system must be roused, as far as it can be done, through the medium of the skin, the mucous membrane of the alimentary canal, and respiratory organs. Friction with a flesh-brush, or with stimulating liniments, or large sinapisms; the application of mustard poultices to the epigastrium, and of warm air, or vessels filled with hot water, to the surface of the body, constitute the plans by which the system is usually acted upon *through the skin*. In the last case which the editor attended, the patient happened to be in a small room in the Fleet Prison, and a good fire having been made, it became like an oven, and had an excellent

effect in contributing to restore the circulation. Frictions with snow or ice have been occasionally tried, but without any decidedly good effect; though Cruveilhier states that he has occasionally had successful recourse to the partial application of ice for the relief of particular symptoms: thus he says, that ice, put on the epigastrium, sometimes stops the vomiting, and alleviates the intolerable uneasiness about the stomach.* Frictions made with snow, on parts affected with cramp, he also speaks favourably of. But besides the means here specified as acting through the medium of the skin, many others have been occasionally tried, as compresses steeped in ammonia laid along the course of the spine; the application of nettles; the moxa; the cautery; touching the back along the spine with a hammer heated in boiling water; or scalding the surface of the body with boiling water. At Paris, the application to the spine of a blister, ten inches long, and two broad, is alleged by Cruveilhier to have been sometimes serviceable.

The *therapeutic means operating through the medium of the mucous membrane of the alimentary canal*, consist of brandy, ammonia, ether, mustard, oil of turpentine, capsicum, oil of capcut, and numberless other articles. Their moderate use in the stage of collapse is undoubtedly necessary; but they ought not to be given without limitation, or too long; for it should never be forgotten that in cholera there is a determination of blood to the mucous membrane of the bowels, and when reaction begins, the tendency to inflammation is very great; however, when the collapse is considerable and protracted, internal stimulants cannot be dispensed with; and in addition to those given by the mouth, others are sometimes injected into the large intestines. Thus a pint or two of warm water, with from four to eight ounces of brandy, and one drachm of laudanum, is sometimes thrown up the rectum, and this even repeatedly, as the editor has seen, not only without ill consequences afterward, but with a degree of comfort to the patient which he has immediately acknowledged.

Opium, which is so useful in choleric looseness, is deemed by some practitioners hurtful in the cold stage, as tending to prevent reaction,

* *Op. cit.*, p. 46. Dr. Paine has long been in the habit of employing ice for the relief of vomiting. "It also allays the thirst, and thus removes one great cause of restlessness. How far it exerts an impression on the morbid action is a subject of inquiry. An extraordinary degree of heat is evolved about the region of the stomach: in one case, in which I applied the thermometer to the surface, a temperature of about 106 degrees was denoted while the patient was expiring. I have imagined that these cases will be more generally benefited by the external application of ice to the epigastric region, than by mustard cataplasms. Ice, too, I have applied advantageously to the head in obvious congestions of the brain, which are frequently attendant on cholera, or arise as one of its consequences. It is also very advantageously applied, for the relief of spasm, to the muscles affected."—*Letters, &c.*, p. 42.

and to bring on the comatose state, in which the patient often dies. In most of the cases attended by the editor and Mr. Hooper, in the King's Bench, opium has been more or less exhibited in the cold stage; but the latter gentleman, whose experience in spasmodic cholera is great, employs this medicine less freely now than formerly. It does no harm, perhaps, in the cold stage; but if reaction take place, it then increases the determination of blood to the head and alimentary canal in a very hurtful degree. The cramps, which appear to call for its exhibition, may be assuaged by it; yet it is to be remembered, that they generally soon cease of themselves.

Emetics, occasionally prescribed in the cold state, for the purpose of rousing the system, is a practice commended by Dr. Brown of Sunderland, and some other practitioners. Cruveilhier conceives that emetics are less objectionable in cholera than they would be if it were a gastritis; and he tells us, that the cases which were treated with ipecacuanha at Paris, were neither remarkable for their successful nor their unsuccessful results. On the whole, emetics may be set down as means of no very great efficacy in this disease.*

Purgatives, especially calomel, as our author has explained, were largely exhibited in India, and the voice of the profession in England is becoming more and more favourable to its administration. Thus Dr. Brown, in speaking of the treatment of the cold stage, observes, that whatever stimulants be employed, calomel, in doses of five or six grains, repeated at intervals of three or four hours, should be given at the same time; it is to be observed, however, that calomel is administered, not with the view of purging, but of affecting the mouth as quickly as possible, and restoring the proper secretions of the digestive organs.

Among the means acting through the medium of the mucous membrane of the alimentary canal, is the solution of carbonate of soda, and of the hydrochlorates of soda and potash.† This medicine has been tried in the King's Bench prison, under the editor's superintendence, but without any very well-marked success. The common sodaic powders, and the effervescing saline draught, are often relished by the patient, but have little or no power over the disease.

The patients are usually greedy of cold beverages, and even of such as are ice-cold. Cruveilhier, after making a comparative trial of these and hot drinks, declares in favour of the latter, the reaction having taken place more quickly and frequently under their use.

* "Where they have been employed in asphyxiated cholera, I think I am warranted in saying, they have hastened the fatal termination. Where they have been employed with success, I have no doubt it has been in what is regarded as the forming stage of the disease."—See Paine's Letters, p. 44.

† Half a drachm of the carbonate of soda, twenty-four grains of hydrochlorate of soda, and six of that of potash are contained in a dose, which is repeated every half hour. Ed.

Of the extract of belladonna, and nitrate of bismuth, in combination, as a means of relieving the vomiting when particularly obstinate, the editor is not in possession of any very precise information.

Great diversity of opinion prevails respecting the propriety of bleeding in the beginning of cholera. In India, the practice was as much praised by some as it was reprobated by others.* When cholera became epidemic, in the district of the King's Bench, bleeding was very frequently practised on the first accession of the disorder; but, by degrees, this measure became less and less resorted to, and now seems to be nearly renounced in the cold stage of the complaint. However, some practitioners in other parts still regard venesection as advisable at first, while the temperature is not below, or but little below the natural standard, the pulse tolerably strong, with the spasms violent, and recurring at short intervals, *provided no collapse has preceded this favourable condition.*† But should this condition, with respect to circulation and temperature, have followed collapse, then Dr. Brown is averse from venesection. In the one case, he conceives that bloodletting breaks the morbid concatenation, and prevents collapse and congestion, and that, in the other, it lowers the vital energies, which are freeing themselves from a state of oppression. But again, in a more advanced stage, when the constitution is no longer balancing between collapse and fever, and the latter may be considered as established, bleeding is a suitable remedy, if the state of the circulation and the general condition of the patient render it necessary.‡ In the decidedly cold stage, however, this physician disapproves of venesection, and, on the whole, his observations on this part of the subject are as judicious as any which have been published. Mr. Annesley assures us, that in India, bleeding, so far from producing syncope, always improved the pulse; and it is represented by many of the practitioners in Asia, as the grand means of preventing the collapse; perhaps they express in different terms the same thing as Dr. Brown has done in a clearer manner.

Mr. Annesley saved nearly all the patients whom he bled; yet here it must be recollected

* Bleeding is supposed, on the whole, to have been more successful in the early stage of the disease in Asia than it has proved in Europe and America. "I entertain no doubt," says Dr. Paine, "that the greater success of this remedy, in the hands of the Anglo-Asiatics, is to be ascribed to the absence of premonitory diarrhoea in the east, and the retention of the fluids in the system," &c. —Op. cit., p. 38.

† In America, bleeding is approved of in the early stage, under the same circumstances as those specified by Dr. Brown. If diarrhoea suddenly invade, and be soon followed by vomiting, without any obvious cause, if the evacuations be scrousy, the tongue clean, the pulse not much depressed, Dr. Paine pronounces this to be a case for venesection, and perhaps for its repetition. —(Letters, &c., p. 24.)

‡ Dr. Joseph Brown, in Cyclop. of Pract. Med., art. CHOLERA.

that this could not have been in the collapse, because then very little blood could have been obtained; the circulation in his examples must have been going on briskly, and therefore they were favourably circumstanced for the practice. As for bleeding in the period of concentration, it is fortunately impracticable; Cruveilhier, who has generally made the attempt in his practice, owns that he could rarely get out of the vein more than a few spoonfuls of blood: he informs us that he never tried arteriotomy himself, but that he knows of some instances in which the brachial was cut through, and only a few drops of blood flowed out of it. After bleeding, he always applies leeches to the epigastrium, and over the sternum and ribs, followed by cupping-glasses.—(Op. cit., p. 50.)

The plans operating through the medium of the mucous membrane of the respiratory organs, comprise the inhalation of oxygen gas, chlorine, and nitrous oxide. Mr. Barnes, of Byfleet, who was in the part of India where the disease first broke out, assures the editor that no plan is equal to this for efficacy; and Dr. Brown informs us, that in some cases in which it was tried in Sunderland, an instantaneous amelioration was manifest, the pulse becoming more vigorous, the lips florid, and the patient freed from præcordial oppression. But, says he, the effect has been generally observed to be only transitory. His own opinion is, that inspired for a few seconds in single bladders, no great benefit is likely to accrue from it; but he would speak less positively of the effect of an atmosphere of diluted oxygen, breathed for a considerable period.*

The oxygen and nitrous gases were tried in some hospitals in America, but without benefit, and even the blueness of the skin was not influenced by them.—(Paine's Letters, &c., p. 52.)

With respect to the proper treatment in the febrile stage, or that of reaction, much difference of opinion prevails. One point, however, seems pretty well determined, which is, that venesection is not indicated in the commencement of the reaction. Cruveilhier has, in several examples, seen the reaction cease immediately after a premature bleeding, the patient become blue again, and the collapse return,

* Cyclop. of Pract. Med. The editor does not deem it necessary to dwell upon the experiments of transfusion, and of injecting into the veins large quantities of a solution composed of twenty-four grains of carbonate of soda, and 3ij. of muriate of soda in five pints of water. The power of this injection in restoring the pulse and giving the natural colour to the skin, is represented as having been exceedingly prompt, though sometimes transient; so that, on the recurrence of the collapse, it might be necessary to repeat the experiment. With respect to transfusion, it has been most fairly tried both in Europe and America: Dr. Paine observes, "We have nearly abandoned transfusion, from its almost uniform failure. The recoveries, I do not think, have been in the ratio of two to fifty. The temporary effect is very encouraging, but the patients soon die."—Letters, p. 16 and 50. One man laughed aloud from the ecstasy of relief, but was a corpse an hour afterward.—P. 51.

quickly followed by a fatal termination.—(Op. cit., p. 51.) Bleeding is not advisable till the reaction is complete, free from perspiration, and accompanied by symptoms of congestion in some part or another. Even then, Cruveilhier prefers several small bleedings to a copious evacuation of blood at once. Leeches are safer than venesection, but require caution: after the reaction has become quite established, the editor has often been much gratified in noticing the vast relief of the suffering about the epigastrium, which they give when applied to this region. When put on the temples and forehead, they are also equally beneficial for the removal of the vertigo and headache resulting from the flux of blood to the brain; an object also materially promoted by the application to the shaved scalp of linen wet with cold water, or an evaporating spirituous lotion.

The fever constituting this stage of cholera is usually attended with more or less inflammation, or a great tendency to it in the mucous membrane of the bowels, and often with vast determination of blood to the head. Hence, after the reaction has been fully secured, a freer use of the lancet and of local bleeding frequently becomes necessary.*

* The ample additions of Prof. Cooper almost supersede the necessity of enlarging on the subject of spasmodic cholera: as the disease, however, has been observed within the last three years by many American physicians, who have contributed to our knowledge of it by a number of respectable publications, we are induced to add a few remarks.

The faculty of the United States, like that abroad, differ in opinion as to the view whether the disease has long been known, or is entirely new. Some of our physicians still debate how far it may be considered as analogous to our indigenous cholera, even when assuming its malignant epidemic form. The distinguished Professor Chapman, of the University of Pennsylvania, affirms (*Am. Journ. of Med. Sc.*, vol. X.), that allowing for the slight modifications which are always impressed on disease by an epidemic influence, the late cholera is essentially the same as our indigenous cholera. The able writer, Dr. Paine, whose work is so favourably noticed by the English editor, expressly states in his Letters (p. 32), "I consider the cholera asphyxia as a nova pestis in Europe and America, and only known in Asia within the last half century. I cannot recognise its parallel in ancient or modern authors. I conceive it to be a fever, of which collapse is the first stage, and reaction the second. The local determinations which arise in the second stage are not necessary to the disease, but are accidental." Professor Ware, of Boston, who visited the cholera hospitals of New-York, thought the disease differed from the character given of it in Europe.—(*Boston Med. and Surg. Journal*.) Again, Professor McNaughton gives it as his opinion, that this epidemic ought to be regarded as an aggravated form of the common cholera.—(*Cholera Gazette of Philadelphia*, p. 133.) On the other hand, Dr. J. W. Francis, of New-York, distinctly asserts, that the cholera which he witnessed in that city was an entire stranger in its pathognomonic characters. "In whatever attire it approaches," says he, "you will find it a stranger. Nosology cannot classify a more distinctive disease."—(See Letter on Cholera As-

The restoration of the secretion of bile, and of its transmission into the intestinal canal, con-

tinues, however, still to be the main desideratum; and hence the approbation given by some

phyxia, p. 32.) But we need not enlarge on this head.

The spasmodic cholera appeared first in North America at Quebec and Montreal, in Canada, about the middle of May, 1832; and in the opinion of many who have closely examined its progress, an intimate connexion seems to be traced between its appearance in Canada and its commencement in the city of New-York about the 1st of the ensuing July, where it was extremely malignant, and was attended with great mortality, inferior only to that which marked its career in Canada. In New-York, the last cases of the disease were seen in the first week of November, and full 4000 fell victims to it. In the beginning of August it appeared in Philadelphia, where upwards of 600 cases occurred in the first week. Shortly after, we find it existing in New-Jersey, Maryland, Ohio, Rhode Island, and various other parts of the United States; and the disorder has prevailed so extensively, that its history merely would occupy a volume of no common size. On this subject the American medical journals, and the *Cholera Gazette* of Carey & Lea, of Philadelphia, may be consulted. In these works the reader will find, among other very valuable matter, the Report of Dr. Samuel Jackson on the Cholera in Philadelphia,—the Letter on Cholera Asphyxia, by Professor Francis,—Dr. Hays's observations on the Pathology of Cholera,—Dr. Eve's Paper on the Asiatic Cholera,—Dr. Heuderson's observations on the Cholera at Washington,—the Paper of Dr. Hopkinson, &c. &c.

In speaking of this disease as it appeared at New-York in 1832, Dr. Francis remarks, "There is no disorder in the nosology more distinctly marked; there is none less liable to be forgotten, when once particularly observed. The declaration is abundantly verified, that the disease almost always commences with a deranged condition of the digestive organs, such as a disturbed state of the stomach and bowels, sickness, and an uneasy sensation in the whole track of the intestinal canal; vomiting, diarrhoea, pains in and about the epigastric region, a sense of weight, heat, burning with thirst at the pit of the stomach, and a feeling of exhaustion. The tongue varies: it is furred, slimy, pale, leaden, red, and occasionally swollen. Sometimes spasmodic contraction of the abdominal and thoracic muscles occurs. The appetite often not impaired, but digestion laboured and imperfect. These, or a part of these, are by some pronounced the precursors of the complaint. When the disorder is more advanced and deeper seated, we generally find a greater distress of the thoracic and abdominal viscera; the spasms are occasionally of the clonic kind, like those of violent colic. There is greater præcordial weight or visceral fulness. The upper and lower extremities lose their temperature, and become colder as the disease advances; the skin is covered with a cold, raw moisture; the integuments, especially of the extremities, seem shrivelled, or sodden, or water-soaked, or doughy; the tongue is cold, sometimes icy; the respiration is more laboured, and the expired air of a chilly dampness; the eyes are sunken, invested with a dark or livid circle; the pulse, which at the attack of the disorder is sometimes more frequent than natural, is now small, contracted, and, finally, can scarcely, or not at all, be felt at the wrist.

"But we are not to depend upon the regular occurrence of the premonitory evidences of the disease, nor of their going through their entire course, as I now trace them, to a fatal termination.

Many cases of cholera have taken place among us, in which the premonitory signs or symptoms were wholly absent, and the complaint has so suddenly invaded, that the stage of collapse has been fully formed within some two, three, or four hours. Nay, death has closed the scene within two or three hours from apparent good health. As in cases of yellow fever, some are violently assailed while walking the streets, or riding on horseback; and I have known three cases of children attacked by the cholera, while in lively exercise at play. A most striking peculiarity of this complaint, in many instances, is, that the intellectual powers, unless overwhelmed by coma, retain their wonted integrity to the last. Often there is an entire absence of all suffering some time before death; and the observation is no less philosophically true than eloquent, that the mind seems to sit unimpaired and serene amid the ruins of organic life.

"I hardly know a greater misnomer of this prevailing epidemic (continues Dr. F.) than the appellation *cholera*. The absence of all bile, either in the ejections by vomiting, or in those from the bowels, is almost pathognomonic: the fluids thus liberated are often brownish, or more frequently colourless, or quite distinct from biliary matter; and if bilious discharges are exhibited, they are among the most favourable circumstances, whether occurring at the invasion of the disorder, or after it has been subjected to the operation of remedial agents. As to the term *spasmodic*, spasm is, perhaps, less frequent in this disorder than in our common cholera morbus. In this opinion I am fortified by the ample experience and observation of my friend, Dr. Hugh McLean, of this city. Spasms do at times occur, and their violence may denote the greater danger of the case; the nervous power being at times rapidly exhausted by their conjoint action, and the causes by which they are induced. Fortunately, in a large majority of instances, these spasms are easily subdued by powerful friction, with potent stimuli. The term *asphyxia* is most consonant to the strongest pathognomonic feature the physician witnesses. This state of asphyxia occurs earlier or later in the progress of the disease, depending upon habit of body, exciting cause, means of relief, &c. I have seen it within a couple of hours from the period of invasion. In some intractable cases it occurs even earlier. This asphyxia seems to me, moreover, to constitute almost the essence of the disorder; for all our prominent indications are to disburden the system of its too deadly grasp, and restore the circulation to its wonted functions. This view of the nature of cholera asphyxia seems to be more clearly established, when we consider the phenomena which the disease exhibits upon inspection after death. Many post-obit observations have been made by physicians of our public institutions, and some few in private practice. The brain has been found surcharged with dark viscid blood; the ventricles, in some cases, containing considerable effusion of serous, occasionally of sanguineous fluid; the membranes often turgid; effusion between the arachnoid membrane and pia mater. Sometimes the arachnoid was deprived of its transparency. In the spinal column were evident traces of previous increased vascular action and effusion. As to the thoracic cavity, the heart and larger venous branches have been found loaded with heavy black blood, often coagulated, and there were at times apparent what the older pathologists denominated polypi. Sometimes the parietes of the heart seemed thinner than natural;

of the most experienced practitioners in this disease to the free exhibition of calomel. The

sometimes the heart was found empty, and powerfully contracted. Discolorations or patches were in a few instances seen on the heart, and effusion within the pericardium. I have seen the blood released from the large veins, preserving the tenacity and appearance of a tarred rope. Dr. Depeyre found in a majority of his dissections, that the lungs were collapsed or shrunk, and frequently natural; others have observed them heavier than natural, or gorged with black blood.

"The abdominal viscera evince to a greater extent the influence of diseased action. The mesentery was, in many instances, overloaded with blood. The appearances of the stomach were various; its contents were occasionally a watery, brownish fluid, or a very pale yellow or turbid fluid: sometimes this organ was found empty and contracted. The mucous coat seemed in most instances affected; and cases were not unfrequent when, upon removing the mucous coat, which could often be easily rubbed off, the inner coat was seen surcharged, and its vessels greatly congested. Sometimes the stomach presented appearances similar to those seen in cases where sudden death has been occasioned by drinking cold water in the summer season, a species of stellular inflammation (ecchymoma) if I may be allowed the words, arising, I suppose, from the inordinate action of the organ when its bloodvessels were so unduly injected. I have a drawing of an example of this sort, and it so resembles others in my possession, taken from cold-water cases, that I felt a good deal strengthened in my pathological views by this coincidence. Examples also might be seen where the stomach was entirely unaffected. In two cases which came under my inspection, the subjects of which had died by violent cholera, the superior portions were exsanguine and colourless, the inferior of a deep vermilion colour, and the pyloric portion thickened and contracted. The small intestines were in almost all instances contracted, occupied with air, and their vascular ramifications loaded with dark blood; the duodenum seems especially vulnerable to the morbid cause, the ileum more disorged than the jejunum, especially its inferior section. All the smaller intestines, I may say, seemed plentifully surcharged, their inner coats softer and paler than natural: rare examples might be found of like morbid changes throughout the whole intestinal canal. The liver was sometimes natural, frequently engorged with dark blood; in several cases the ducts were entirely obstructed or strictured: the gall-bladder was most generally empty, or possessing a small quantity of dark bile: the pancreas bore little or no particular marks of increased vascular fullness: the spleen varied, and was sometimes surcharged."

In many respects, Dr. Francis's account of the morbid appearances on dissection correspond with those recorded by the English editor, as taken from the work of M. Cruveilhier. The autoptic examinations made by Dr. Ferris, principal of the Duane-street Hospital, during the cholera of 1834, are stated to have been as follows: the brain was rarely congested, the arachnoid membrane was occasionally found highly vascular: extensive inflammation was frequently seen in the stomach, more particularly at the pyloric portion: the small intestines were very generally found highly inflamed, and often engorged: the liver rarely affected: the spleen generally natural, sometimes engorged: the gall-bladder often full, containing a dark, olive-coloured bile: the bladder was found entirely empty and contracted, in all who died

editor has seen more patients saved by calomel, than by any other single remedy. Two grains

during collapse: in some cases, when the sufferer had recovered from that state and finally died, some urine was seen. These examinations were all limited to temperate subjects. In some of intemperate habits, occasional appearances of greater local congestion and of more extensive inflammation were seen.

The results of Professor Horner's dissections of cholera cases show, "1st. That the vascular derangements and phenomena of Asiatic cholera, as exhibited in the alimentary canal, are confined almost exclusively, if not entirely, to the venous system. 2d. That in the earlier stages, a lining membrane of coagulating lymph exists in the small intestines at least, if not in the stomach and colon also; and that this lining resembles the membrane of cramp. 3d. That in addition to the enlarged and tumefied follicles described by M. Bouillaud, and a similar enlargement of the intestinal papillæ described by M. Serrey, a copious vesicular eruption, entirely distinct from both, and easily distinguished from them, exists on the mucous membrane of the stomach, of the small intestines, and of the layer: and that this vesicular eruption, consisting of small spheres, seldom more than the sixtieth part of an inch in diameter, is probably the essential morbid character of the disease, as is the case with the eruption of small-pox and of other affections. 4th. That the follicular system of the alimentary canal is not the principal fountain of the sero-fibrinous discharges, commonly called the cholera fluid, but that the latter comes from the capillaries of the venous system."—See Am. Jour. of Med. Sc., No. xxx.

In an extremely interesting paper on the cholera, as it appeared in Vienna, in 1831, published in the Boston Medical Magazine, vol. i., No. iv., my friend, Dr. C. T. Jackson, of Boston, has communicated his observations on the morbid phenomena which were seen upon inspection after death. From this valuable paper the following extract is made. "When we examine a corpse dead of cholera," says Dr. Jackson, "we remark a livid purple or blue colour of the skin over the whole surface of the body, but more strongly marked at the extremities; the skin of the fingers on the palmar face is wrinkled, and the tips of the fingers and toes have deep furrows within, produced by this means. The eyes are deeply sunken, and have a dark-bluish black ring round the orbits. The conjunctiva is congested with blood, and has a glassy lustre—the flexor muscles are rigidly contracted, the tendons standing out prominent on the extremities; the hands are firmly clinched, requiring an effort to open them. Tongue covered with a brown slimy coat; mucous membrane of the mouth covered with an adhesive mucus—uvula, tonsils, and pharynx covered with granulations, as is likewise the base of the tongue. These granulations vary in size from that of a peppercorn to that of a pea, and are probably the mucous follicles altered by inflammation. They contain a yellow pus of more than ordinary consistence. Œsophagus corrugated. Mucous membrane of the stomach often thickened, and is of a delicate pink colour, or is brownish yellow, with spots of redness, as if from recent inflammation. These red spots have often little rounded vesicles of the shape and size of half a pea, projecting from the centre, which contain a liquid pus. We noticed the presence of vesicles in three instances in the stomach, where we first discovered them. Afterward we found them very common in the whole track of the small intestines, but did not find them so frequently in the

may be given every three or four hours, and, if assisted with some gentle laxative occasionally, as carbonate of magnesia, castor-oil, or the

stomach. These vesicles are probably mucous follicles altered by inflammatory action. Stomach and intestines are filled with a turbid liquid like rice-water, with little flocculi of a white membranous substance floating in it. The fluid in the intestines is coloured more or less by fecal matter and bile.

"The glands of Peyer are enlarged in cases where the disease has been protracted into the typhoid state. The glands of Brenner are often in these cases rendered visible, are large as peppercorns, and have black points at their centres. Valvula conniventes of the duodenum, flaccid, thickened, and swollen—covered with the little vesicles before mentioned—more rarely they are ulcerated. Peritoneum dry, adhesive to the touch, and has a shining opaline lustre. The bile-ducts are often thickened, but are generally open. Liver dry; gall-bladder filled with a brownish liquid bile. Spleen small, flaccid. Heart large, flaccid, soft, easily torn by the fingers—contains blood in all its cavities. The blood is imperfectly coagulated, resembling thick molasses. It adheres to the surface of the heart, and gives it a dark colour. The blood is black, or venous blood, in both ventricles and auricles. The *pulmonary veins contain clots of yellow coagulated lymph, tremulous like jelly*. Mr. Wagner considers this a peculiar phenomenon. The state of the blood is like that I have observed in persons dead of diabetes mellitus. Is it not the effect of a drain of serum from the blood during the vomiting in cholera, and by urine in diabetes?"

"In the organs of respiration we find the trachea containing frothy mucus of a brown colour. Vocal cords of the larynx flaccid, sometimes thickened. Mucous membrane of larynx sometimes red and congested. Lungs somewhat contracted in volume, are tough and leathery to the feel, but *crepitate well, and never contain tubercles*. Kidneys have the veins full of uncoagulated blood. Bladder firmly contracted in a small mass beneath the pubes. It is generally empty, or contains a drachm of opaque liquid. Brain has the sinuses engorged with uncoagulated black blood. The cerebral mass firm, tough, and dry. In cases where the disease was of a long duration before death, we found the brain congested. This was peculiar to the typhoid state. Medulla oblongata firmer than ordinary, and contracted in volume. Medulla spinalis congested with blood from gravitation after death. Semilunar ganglion was found sometimes enlarged, of a deep red colour; and sometimes softer than natural: the state of this ganglion, however, varied so much, that I can give no precise account of its morbid anatomy. It is obvious the changes of colour in this ganglion might have been the effects of the change in the colour of the blood. But little is known of the morbid anatomy of the ganglionic nerves, and we have no data on which to found our comparisons—hence it is difficult to say what part their lesion might have performed in the cholera."

For farther interesting views of the morbid appearances of cholera, see Cases of Cholera collected at Paris, in April, 1832, in the wards of MM. Andral and Louis, at the Hospital La Pitié, by James Jackson, jun., a young man of great promise, and the pamphlet of Dr. Ashbel Smith, of North Carolina.

The methods of treatment pursued by practitioners in the United States, differ as much as their pathological views of the nature and charac-

ter of this malady. The early use of the lancet in the incipient stage of the disease has been urged by many, and some have recommended it even in the collapsed state: others proscribe bloodletting altogether: there is probably error in both these extremes. Dr. Ferris found the lancet an admirable aid in many cases of the forming stages of this complaint in 1834. A very eminent physician of Mississippi, Dr. Cartwright, tells us that he used freely calomel, camphire, and cayenne pepper with great success: he also states, that he had recourse to bleeding, if there was local distress in the head.—(See Additional Observations, &c., Natchez, 1833.)

In short, the opinions of American physicians on the subject of bloodletting correspond with those expressed in the late Croonian lectures delivered by Dr. Roupell of London. Speaking on this subject in general terms, he remarks, "Venesection, of all remedies that have been recommended in cholera, is that which is most confidently spoken of, and which is supported by the best authorities. Sure, in common with other remedies, bleeding is said to have had its failures."

In regard to the further treatment of this disease Dr. Francis remarks, "You may distinctly observe three stages in the complaint: first, that which embraces the forming or premonitory symptoms, such as I have already stated; more or less of these will invade every subject, and they will vary in force in different individuals, and be modified by accidental circumstances. The second stage constitutes that period when the disorder is further advanced, when the visceral congestion has taken place, accompanied perhaps by spasms, oppression of the intellectual faculties, and a tardy circulation. The third and last stage is that of collapse, frequently, alas! the fatal stage. Accordingly, therefore, as our means of relief are applied to these different stages, will they more or less differ. In the first or forming stage, attention to the *primæ viæ*, relieving the bowels of their wonted crudities, and adjusting the common functions of the system, are the objects to be fulfilled. A dose of castor-oil, repeated perhaps, the administration of the common eccoprotic mixture of rhubarb, magnesia, and mint-water, or a liberal dose of calomel with a few grains of aloes, or jalap and crem. tart. may suffice. Hundreds of cases, in the incipient form of cholera, have by these means been arrested; and we are further to remember, how essential it is that the feculent discharges should be restored to their ordinary natural character. In the second stage, that of congestive formation, while we attend to the condition of the *primæ viæ*, let us not forget the importance of bloodletting, the internal use of calomel, blended at times with very small doses of opium, when irritability of the stomach, a tendency to spasm, or other morbid symptoms, point out the combination, the application of blisters to the abdomen, or sinapisms largely applied over the epigastric region; tepid fomentations up the bowels, by means of enemata of water, catnip tea, &c.; the free use of frictions of a stimulating nature, renewed again and again, to restore the harmony of the circulation, diminish coma, and relieve the labouring viscera. In the third stage, that of collapse, all our efforts will too often prove unavailing. Yet the success which has resulted, in numerous instances, even in so discouraging a state, justifies the physician in assiduous perseverance. Some prescribers, even in

Too often, however, whatever treatment be pursued, the reaction is either incomplete, or brings on inflammation at various points of the system, leading to a fatal result, either in its acute or chronic form. Hence, as Cruveilhier remarks, the prudence of employing internal stimulants and emetics with moderation. In other instances the patient dies in a comatose or typhoid state, and numerous are the practitioners who have repented of having exhibited opium too freely in the cold stage. This species of cholera is not exempt from peril even in the period of convalescence, and after the patient has got through the cold and febrile stages, he frequently falls a victim to the slightest error of regimen.*

this state, have recourse to the lancet; if blood can be drawn from the arm, this is a reason for persisting in the attempt: in despite of the most disheartening prospects, by local hot bathing, or by frictions, the blood has at length flowed, the pulse relaxed, the heart been relieved, and the circulation restored. But this happy event is of rare occurrence; the cerebral congestion, the abdominal fulness and tension, and perhaps pain, upon pressure, now call in, as proper auxiliaries, leeching, cupping, followed by the extensive application of mustard and vinegar cataplasms to the bowels and feet, bottles of hot water to the feet, almost unremitting efforts in exciting the surface, by frictions with warm flannel or the flesh-brush: and among the liniments now most employed, are the two following—equal parts of brandy, camphorated spirits, and cayenne pepper; or spirits of turpentine, camphorated spirits, and cayenne pepper: the body in general, and the superior and inferior extremities, are to feel the effects of a free attrition with the liniment, renewed at short intervals: some use hot vinegar and cayenne pepper—others freely aq. am. Dr. Roe, of the Greenwich hospital, instead of these means, employs very generally, mercurial ointment, with camphor and cayenne pepper. The prescription is as follows: Ung. mercur. one pound; pulv. capsic. ann. four ounces; camphire eight ounces. He rarely uses internal remedies.

"As a means of quickly rousing the cold surface, and acting on the deserted capillaries, Dr. Dekay uses, and, I am informed, with happy effect, equal parts of cayenne pepper and camphire; and lard, blended with a moderate quantity of muriatic acid, as a rubefacient, is reported to be very rapid in its action. The actual cautery has been applied, and some have had the temerity to make use of enemata of tobacco. I do not think that due value has been placed upon the use of copious intestinal injections of warm water, with or without salt, in the different stages of the disease. I have used most freely, in the collapsed stage, the liniment of turpentine, camphire, and tincture of capsicum, sometimes with cajeput oil, tincture of flies, &c. and in several appalling cases in this stage, with entire success.

"Some of our physicians, imbued with the Broussaisian doctrines of disease, urge, as the most efficient cure, the liberal application of leeches, and the internal use of ice. The application of leeches, either to the head or to the abdomen, or to both, provided their employment be timely, must be beneficial; and ice, in small quantities, repeatedly taken in the manner of pills, has in a number of instances allayed very irritable stomachs, and proved salutary in diminishing that inordinate burning and thirst which some patients

GENUS X.

ENTEROLITHUS.

INTESTINAL, OR GASTRO-INTESTINAL, CONCRETIONS.

STONY CONCRETIONS IN THE STOMACH OR INTESTINAL CANAL.

WHATEVER be the degree of merit or demerit that belongs to this genus, the author suspects he must take to his own share; since, so far as he knows, it is yet new to the domains of nosology.

In treating of the genus *COFROSTASIS*, we had occasion to observe, that the natural feces, under circumstances there explained, become at times indurated, shrivelled, and broken down

suffer. But this practice, however, is not energetic enough, and I apprehend few severe cases of cholera, much less those of approaching collapse, have been cured by it.

"There is a state of reaction which occurs in some instances," adds Dr. F., "when the patient survives the collapsed stage, which much resembles a depressed, continued fever: the coma, the suffused countenance, the slight febrile heat, restlessness, pulse, &c. sufficiently designate it. I need not dwell on the treatment. In this consecutive fever, which is often greatest where internal stimuli have been injudiciously used, blood-letting or cupping may be advantageously employed: the alvine excretions are to be removed, which are often enormous in quantity, and offensive, and the case subjected to the common principles of cure. In this sequela there is great debility, which will often continue ten or fifteen days."

When speaking of the treatment by injecting saline solutions into the veins, Dr. Francis remarks, "Of about forty-two subjects, in which our practitioners have had recourse to this method of treatment, four only, as far as I can learn, have been thereby saved. Two of these successful experiments were made in the Crosby-street hospital, under the charge of Dr. Rhinelander, where, I believe, thirteen cases have been tried. In the first successful one forty ounces were injected, of a solution composed of the carbonate of soda one drachm, of muriate of soda two drachms, dissolved in six pints of water. The patient was a female, in the collapsed state. In the other successful case, a female, in like hopeless condition, had a similar injection, to the extent of one hundred and five ounces. The largest quantity of the saline injection that has as yet been introduced by Dr. Depeyre, by whom the two fortunate experiments were made, was three hundred and thirty-two ounces. The injection was made of the temperature of blood warmth, or rather higher, and introduced into the median cephalic vein. From the examples which I have seen of this practice, I should deem it justifiable only in the extreme instances of collapse, when every other prospect of cure was lost. In such forlorn condition the saline injections are fully justifiable."

On this subject Dr. Vaché, of New-York, very properly observes, in his letter to Dr. Francis, (U. S. Med. and Surg. Journal, vol. i., No. 2, p. 50) that "this remedy became a powerful auxiliary to a speedy recovery, provided the sudden and violent reaction induced be energetically met by corresponding antiphlogistic means."—D.

* Cruveilhier makes some very judicious reflections on this part of the subject.—Anat. Pathol., livr. 14me., p. 52.

into small balls and buttons, as hard as sun-burnt clay, occasionally intermixed with mucus, or oleaginous matter. And, in treating of colica, we referred to concretions of a still harder substance, and of a stony appearance, which, though formed in the intestinal channel, are compounded of other materials than the constituent principles of feces.

It is for the purpose of including substances of this kind, and which are of very different descriptions, that the present genus has been devised, whose name, ENTEROLITHUS, or INTESTINAL CONCRETIONS, sufficiently indicates a comprehensive scope.

We have, indeed, on various occasions, had to give a casual glance at this subject before; and we have particularly observed, that almost all animals are endowed with a power of separating or secreting lime and other earths from the blood for particular purposes, as that of forming a shell-covering in insects and worms, and of giving hardness to the bones in all other animals. Under a morbid action of single organs, or of the system generally, this secretion often takes place in an undue abundance, and is poured forth into cavities where its accumulation and crystallization must be attended with mischief. Such, at times, is the case in respect to the stomach and intestines. But, independently of concretions derived from this source, we often meet with others, produced by an agglutination or crystallization of substances which are contained in the aliment, and which, not unfrequently, give immediate proof of their origin by the aromatic taste, smell, or other qualities which they exhibit. There is also a third species of concretion, occasionally to be traced in the alvine channel, of a harder or softer structure, and of a ceteaceous or saponaceous feel, which consists of feces, or the refuse matter of the chyle, more or less combined with oil or mucus, and sometimes consisting almost entirely of the two last.

As the subject has been never before pursued with a view to any critical examination or systematic arrangement of the tribes of substances that appertain to it, we have not yet perhaps arrived at a knowledge of all their different forms or combinations, as met with in the intestines of man, or the animals of the mammalian class, to which man is degraded by Linnæus: but we may at least venture upon the three following, each of which will furnish a distinct species:—

1. Enterolithus Bezoardus. Bezoar.
2. ————— Calculus. Intestinal Calculus.
3. ————— Scybalum. Scybalum.*

* Intestinal concretions, in relation to their origin, may be divided into three kinds. The first are not formed in the alimentary canal, but pass into it from some other part, as the liver or gall-bladder, and then undergo more or less modification. The second are only partly formed in the alimentary tube; they have a nucleus, usually something that has been swallowed, round which a certain number of principles contained in that

SPECIES I.

ENTEROLITHUS BEZOARDUS.

BEZOAR.

FOUND IN CONCENTRIC LAYERS, CLOSELY AGGLUTINATED OR CRYSTALLIZED; CAPABLE OF A FINE POLISH; FREQUENTLY WITH A METALLIC LUSTRE ON THE SURFACE OF EACH LAYER, AND AN ACCIDENTAL NUCLEUS IN THE CENTRE; OF A SPHEROIDAL FIGURE: CHIEFLY CONSISTING OF VEGETABLE MATTER.

BEZOARDUS, or bezoar, is derived from the Persian compound *Padi-zehar*, or *Pad-zehr*, corrupted into *bedzohr*, and bezoar. Literally translated, it is *depellens venenum*, and consequently a direct synonyme with the Greek term alexipharmic.

It is found occasionally in the stomach of some of the camel tribes, but more frequently in that of the smaller ruminating quadrupeds, as the goat, and two or three species of the antelope genus, as the chamois, or *wild-goat*, as it is sometimes incorrectly called, (*the antilope rupicapra* of Linnaeus), and especially that beautiful and elegant animal, the *gazal* (*antilope gazella*, Linn.), the tzebi (צִבִּי) of the Hebrew poets, or *roe* of our Bible versions.

The bezoar was formerly employed as a febrifuge and alexipharmic in medicine, and worn as an amulet by the superstitious, who have sometimes purchased a single one from the east at six thousand livres when very fine, and hired them in Holland and Portugal, on particular occasions, at a ducat a day.

It is not quite satisfactorily ascertained, that this species has ever been found in the human stomach; we have, indeed, assertions to this

tube accumulate and crystallize. The third are entirely produced in the alimentary canal itself. To the first kind must be referred the calculus found by Dr. Marcet in the rectum of a child which had an imperforate anus, but between whose rectum and bladder an open communication existed. The foreign body consisted principally of phosphate of lime and the ammoniacomagnesian phosphate.

Whatever may be the origin or composition of intestinal concretions, the irritation arising from them is apt to bring on eructations, frequent vomiting, constant pain and oppression about the præcordia, loss of appetite, constipation, and almost total loss of sleep; and a gradual impairment of the health. In some instances diarrhoea prevails: the result may even prove fatal. One remarkable case of this kind is on record, where, after the death of a patient, a boy eleven years old, a calculous concretion was detected at the union of the ascending and transverse portions of the colon. It was six inches long; weighed twelve ounces and a half; was enveloped in mucus; and consisted of three fragments articulated, as it were, with one another. A hard tumour was felt in the right hypochondrium while the boy lived, but it was supposed to be the liver.—(See Edin. Med. and Surgical Journal, July, 1825.) The bad symptoms occasioned by intestinal concretions may continue until the foreign bodies are expelled. In certain cases, the complaints produced by them are ascribable to the manner in which they mechanically block up the pylorus or the intestines.—Ed.

effect in various foreign miscellanies,* and I have hence introduced it into the present place. But it does not often appear that the substances referred to were examined with sufficient attention, while the authors seem to have used the term bezoar in a very loose and indefinite sense. In one of the volumes of the *Annales de Chimie*, however, the analysis seems to have been scientifically conducted. It was made by M. H. Bracconot, from a quantity of concrete materials voided by a female under the care of Dr. Champion, of Bar-le-duc, which were found to be genuine bezoars.—(*Annales de Chimie*, tom. xx.)

The bezoar, as already observed, is chiefly obtained from the stomach of the smaller ruminating animals, whose food, from the complexity of the organ, lies for a long time quiescent in a state of subaction, and is thus enabled to give forth the whole of its juices under circumstances that afford them a much easier opportunity of agglutinating or crystallizing than in many other animals. In the goat kind, these concretions are called *ægagropilæ*; a Greek term, signifying mountain-goat balls. They are of different sizes and figures, the last being chiefly determined by the nature of the nucleus, which, in different individuals, is marcasite, talc, flint, gravel, straw, glass, seeds of plants, &c. In colour they are white, yellow, or brownish; that of the gazhal is greenish blue; and, when recent, highly aromatic, from the odour of the plants on which the animal feeds. The most singular circumstance belonging to them, is the bronze or metallic lustre that appears on the surface of the different layers, and does not strike deeper than the surface. This, however, is said to be a property peculiar to the western bezoar, and seldom or never to be found in those of the east, which are often of as beautiful a glossy white as ivory. Daubenton ascribes the gilt appearance to a vegetable die, fixed by the tartaric acid of the plants in which the die exists; and observes, that he has remarked a like appearance on the grinding teeth of many of the ruminating tribes. A few of them rattle on being shaken, the nucleus having contracted and become loose. La Fosse (*Cours d'Hippiatrique*, p. 158) asserts, that he has occasionally met with genuine bezoars or *ægagropilæ* in the stomach of the horse; and similar concretions seem at times to be formed out of the animal body, as tubercles to the roots or other parts of certain plants; for Fourcroy affirms, that, in the cabinet of Jussieu, he was shown some curious bezoars of the oriental appearance, white or yellowish, glossy as ivory, and of a spheroidal figure, which were said to be produced by the cocoa.

From the supposed value of bezoars in medicine, they were at one time imitated, and the false sold as genuine. These supposititious stones, according to Bomare, were compounded of lobsters' claws and oyster shells, levigated

on porphyry, made into a paste with musk and ambergris, and formed into balls of the shape of bezoars; and, where the metallic lines were aimed at, afterward rolled on gold leaf. The pierres de Goa, or de Malacca, as they were called, were, at least generally, factitious bezoars of this kind; and their spuriousness was capable of proof, by drawing a line with them on a piece of paper previously rubbed over with ceruse, chalk, or lime; the line of the genuine bezoar turns greenish, or of an olive yellow; that of the factitious remains unaltered. The imposition, however, seems to have been very unscientific, as formed principally of earths, instead of being elaborated from crystallized vegetable juices, which produce this change of colour

SPECIES II.

ENTEROLITHUS CALCULUS. INTESTINAL CALCULUS.

RADIATING FROM A COMMON CENTRE, OR FORMED IN CONCENTRIC LAYERS; MOSTLY WITH AN ACCIDENTAL NUCLEUS; MORE OR LESS POROUS; SPHEROIDAL OR OBLONG; ADMITTING AN IMPERFECT POLISH; COMPOSED CHIEFLY OF EARTHS AND ANIMAL MATTER.

This species is by no means unfrequently found in the human stomach and intestines, but far oftener, as remarked above, in the digestive channel of other animals, and particularly in the larger ruminating quadrupeds, or those with a long complicated digestive organ, where the food, as in the formation of the bezoars, is slowly carried forward; and in tardy draught-horses, particularly those of millers, that are fed largely on bran, which seems to yield a ready basis for these concretions.* In Dr. Watson's case, the disease had existed for years: the animal died, aged twenty-two, near foaling; but gave no sign of pain or inconvenience till three months before her death. The calculus weighed 15lb. 12oz.; average diameter $8\frac{1}{2}$ inches by 8 inches.

When chymically analyzed, they are chiefly found to consist of a triple or ammoniaco-magnesian phosphate, like the earthy or white-sand calculi of the human bladder; though it is difficult to conceive from what quarter the magnesia is obtained. In the case of millers' horses, some portion of this earth may perhaps be derived from the bran, in which it is always to be traced; but the difficulty still remains with respect to other animals. The figure, whatever be the size of the calculus, is usually spheroidal, except where broken into separate fragments: the matter is deposited for the most part as in the former species, upon a nucleus of some sort or other; as a small piece of flint, an iron nail, a seed or husk, a piece of hay or straw, a bit of bone, with blood originally effused round it (*Laugier*, in *Mém. de l'Acad. Royale de Méd.*, t. i.); the structure sometimes radiating from

* Samml. Med. Wahrnehm., b. ii., p. 418. Ferri, *Galeria de Minerva* 1696.

* Phil. Trans., xxiv., 1705, Thoresby. Id., xlv. 1746, Bailey. Id., xlviii., 1745, Watson.

such common centre to the surface, and sometimes evincing distinct plates, more or less united to each other.* In the human subject, these calculi vary from the size of a pea to that of a filbert, chestnut, or hen's egg, and are often still larger.† In the case of Margaret Lawer (related under *Colica constipata* (*Ut supra*, p. 124), they were usually of the two former sizes, and appear to have been formed in great abundance, and with wonderful facility; for her abdomen, upon pressing it, often rattled, from the quantity it contained, with the sound of a bag of marbles. Many of these were rough and sharp-pointed at the edge, evidently fragments or nodules of larger concretions, and gave great pain in the rejection, whether above or below, for they were discharged both ways. The larger-sized weighed rather more than two drachms; and Dr. König, who relates the case, calculated that the whole that were discharged, during the continuance of the complaint, could not amount to less than 5 lb. avoirdupois. In a case related by Mr. Martineau (*Phil. Trans.*, vol. xxxii., 1722–1723), some of them, much larger than the preceding, were voided *per anum*, by a poor woman in the third month of pregnancy, after having suffered from colic about four or five days: of these, the largest, 8 inches in circumference, and 6½ inches in length, weighed two ounces, 16 pennyweights, and 12 grains. In this case, and in various others, the calculi seem to have been in the intestines for a considerable period of time without inconvenience; for it is hardly possible to conceive that all these should have been produced in the course of a week. In another case, in the same journal (*Phil. Trans.*, vol. xli., 1739–1741), a calculus of this kind was extracted with some difficulty from the anus by the surgeon who attended, which weighed eight ounces and a half, and was ten inches and a half in circumference. It is described as “a hard, unequal, ragged, flinty stone,” but was not examined chymically. It had been in the pelvis, and nearly of its full size, for several years before its extraction; for the patient's stools were always obtained with difficulty; and three children, which she had successively borne in the three preceding years, were all marked with a large hollow or indentation in some part of the head; in one instance, of sufficient extent to hold the moiety of a small orange.

Other examples, however, have occurred, both of as large a size, and of as firm or flinty a crystallization. Thus, in a foreign miscellany of authority, we have the case of a calculus discharged by the anus of half a pound weight (*Samml. Med. Wahrn.*, band ix., p. 231); and

M. Daabal has published a full account of fragments of stony calculi (*saxea fragmenta*) evacuated from the same organ (*Discursus Academicus de Esthira Norra.*, Lund., 1715, 8vo.); as Sir H. Sloane has another case, in which the concretions amounted to two hundred.—(*Birch. Hist.*, 1685.)

In draught-horses and oxen, this species of calculus is generally found single and much larger, and often of little inconvenience for years. They vary in size from 3 lb. avoirdupois to 10 or 12. Of this last weight, the author once met with an instance in a horse belonging to Mr. Hayward, a respectable miller of Brundon, near Sudbury, in Suffolk; and Mr. Watson gives an account of two considerably heavier, one already noticed, and the other weighing 19 lb., exclusive of the outward shell or crust, which was broken off in several pieces, with a circumference of 28 inches. Both these were laminated, but “had the appearance of a pebble; yet the specific gravity was much lighter, the first weighing in water not more than 6 lb. At other times, the crystallization is more like that of gneiss, or of grit-stone, and almost always light and porous.”*

Occasionally, however, this species is found gregarious instead of solitary. Mr. Watson, in the article just quoted, mentions a case of several found in the intestines of a mare, and presented to the Royal Society by the Duke of Richmond, in 1746, the nucleus of two of which was found to be an iron nail. And by turning to another volume of the same journal (*Phil. Trans.*, vol. xlv., 1746), we find these calculi described by Dr. Bailey (for the two articles appear to relate to the same case) as consisting of five in number, of different sizes, some triangular, and resembling a horse-bean, of an olive colour, and finely polished; and one much larger, weighing nearly 16 oz. troy, and measuring 12 inches by 11.

Several of these concretions, we have observed, had the appearance of crystallized gneiss, or of grit-stone; and it is probable that they were partly of these very minerals; for it is of such that millstones are very generally composed; and by the friction they are perpetually undergoing, there can be little doubt that much of the milldust, intermixed with bran, with which millers' horses are fed so largely, is derived from the powder furnished by these stones.

In man, the calculus often depends upon a like accidental origin; for it not unfrequently follows upon a long, free, and injudicious use of prepared chalk, magnesia, or other calcareous earths, for the purpose of correcting acidity in

* A female child swallowed a pin, which was not voided from the bowels till she attained the age of eighteen, when its head and one half of the other portion of it was found enclosed in an earthy concretion.—(*North American Journ.*, 1827.)—Ed.

† Those of considerable dimensions may cause hard swellings in some of the abdominal regions very manifest to the touch, and sometimes even to the sight.—See *Edin. Med. Journ.*, July, 1825; and *Archives de Médecine*, t. ii., p. 148.

* *Phil. Trans.*, vol. xxxiv., No. 398. In the centre of a calculus taken from a horse, and consisting of phosphate of lime, M.M. Laugier and Lassaigne found a large quantity of straw, around which the earthy matter had been deposited.—See Andral, *Anat. Pathol.*, t. ii., p. 166. In the intestines of cows, and some other animals, balls of hair are common enough. They lick their hairs, and a portion of these, being swallowed, concrete into hard balls, cemented with phosphate of lime and mucus.—Ed.

the stomach.* I have known this happen in many dyspeptic cases; and once attended a lady, who, from the same cause, laboured under a most painful constipation, till a large mass of what may be called intestinal mortar was removed by a scoop from the rectum. The case related by Dr. S. Fitzgerald, of Mullingar, was apparently produced by a like cause. The lady had suffered great torture in the hypogastric region, particularly towards the back and os sacrum, for eighteen months; during the last three of which she could not leave her bed, except for tepid bathing, which afforded her transient ease. Upon the rejection of an emollient anodyne clyster, she discharged with it a large hard calcareous ball, of an oval figure, weighing eight ounces and three drachms, exceeding in size an ordinary orange, and so solid that nothing less than the stroke of a hammer could break it. A total liberation from pain immediately followed, and the patient progressively recovered.†

The curative process may be comprised in a few words. If the concretions proceed from an injudicious use of calcareous or magnesian earths, both these must be avoided for the future: and the calculi actually existing be diminished in their diameter by the use of mineral acids, and quickened in their passage by cathartics. If magnesia be the agglomerating base, the sulphuric acid will be preferable, as this will have a tendency to convert it into Epsom salts, and thus produce a purgative as well as a solvent effect. [The state of the rectum should always be ascertained, and by throwing a clyster up it, it will generally be easy to learn whether any obstruction exist

* In some instances, carbonate of iron has accumulated in the bowels, and produced concretions. Hence, when this medicine is given, Dr. Elliotson recommends particular care to be taken to keep the bowels open; if you attend to this point, an immense quantity of the carbonate of iron may be given without inconvenience. The same physician relates a case of tetanus successfully treated, where a man took nearly two pounds of it every day for some days, and he regularly voided large lumps of it, clysters being given to make their passage free from pain. Dr. Elliotson had another patient labouring under tetanus, to whom he gave this remedy also with success; but if purgatives were not regularly administered, pain was experienced in the rectum from the accumulation of the iron in it, which required to be picked out. Some years ago, when it was the fashion to cram the alimentary canal with mustard-seed to obviate costiveness, considerable masses of it frequently collected in the bowels, and produced serious disorder.—Ed.

† Edin. Med. Com., vol. viii., p. 329. Among the poor in Scotland, who eat oat bread, Dr. Marcet found that intestinal concretions occur, with a nucleus of vegetable fibres, manifestly consisting of oats. An analysis of one of these concretions furnished of

within it; or, if requisite, an examination may be made with the finger or instruments. It is not at all uncommon for the concretions to pass as far as the rectum before they stop.]

If we have reason to suspect a calcareous diathesis as a sole cause, since this diathesis usually depends upon debility, we must endeavour to invigorate the system generally, and the stomach more particularly, by the course of regimen and medicines already prescribed under DYSPEPSY.—(Marcet, *Essay on Calculous Disorders*, 1817.)

SPECIES III.

ENTEROLITHUS SCYBALUM.

SCYBALUM.

CONCRETION SOAPY OR UNCTUOUS; MOSTLY CONTINUOUS; SOMETIMES IN LAYERS; SPHEROIDAL OR OBLONG; CONSISTING CHIEFLY OF MUCUS OR OLEAGINOUS MATTER, MORE OR LESS INTERMIXED WITH INDURATED FECES.

This species has not hitherto been sufficiently attended to; and even Fourcroy and Walther seem to have mistaken it for a biliary calculus; an error which the writer has seen in several instances repeated in this metropolis. The specific character sufficiently expresses the general nature of the concretion, and is drawn up from various examples that have occurred to himself, or have been shown him by others.

The concretions belonging to this species, if carefully watched and analyzed, would probably be found very numerous; but in the present state of our knowledge upon this subject, we must confine ourselves to the three modifications of feculent, oleaginous, and ambraceous, or that of ambergris.

When, from a feeble peristaltic action, the feces have remained long in the colon, they are frequently found to undergo a considerable change; for they become harder as their more liquid parts are absorbed; and in consequence of becoming harder, frequently stimulate the mucous glands, by which they are surrounded, to a more copious secretion, which intermixes with them; and, as they break into indurated balls or fragments, gives them a less rough, or a more greasy or unctuous feel. These are the common scybala of medical writers.

But we occasionally meet with balls, buttons, or globules of a still more cetaceous, fatty, or oily substance, discharged, sometimes solitarily, sometimes gregariously, from the rectum, of very different diameters.* Occasionally we can trace them to a like origin, as in a case quoted by Sir Everard Home (*Phil. Trans.*, year 1813, art. xxi.), from Dr. Babington, in which the lady who voided them had regularly, before their appearance, taken one or more

* A phthisical girl voided from the bowels numerous concretions, which were found by M. Lassaigne to be composed as follows:—

1. Acid fatty matter,	- - -	74
2. Matter analogous to fibrine,	- - -	21
3. Phosphate of lime,	- - -	4
4. Chloruret of sodium,	- - -	1—Ed.

doses of olive-oil to appease severe pains in the stomach, which were ascribed to the passing of gall-stones, for which these concretions were at first altogether mistaken. They were of a globular form, "varying in size from that of a small pea to the bulk of a moderate grape, of a cream colour, and slightly translucent, of a sufficient consistence to preserve their form, and to bear being cut with a knife like soft wax."

In general, however, we cannot trace these concretions to any unctuous material introduced into the stomach; and have reason to believe them produced by intestinal secretion, or a chymical change effected on the recement of the food after it has passed into the larger intestines. Dr. Babington has also furnished, in the same article, a case, which can only be resolved into an origin of this kind. The patient was here a little girl of four years and a half old. At the age of three, "her mother observed something come from her as she walked across the room, which, when examined, was found to be fat in a liquid state, and which congealed when cold. Ever since that time to the present she has voided, at intervals of ten or fourteen days, the quantity of from one to three ounces, sometimes pure, at others mixed with feces: when voided, it has an unusually yellow tinge, and is quite fluid like oil. Her appetite is good, as well as her spirits, and her flesh firm; her belly rather tumid, but not hard: she is subject to occasional griping."—(Loc. cit.) A free evacuation of the same kind occurred to Dr. Kuntzmanz of Berlin.—(*Journal der Practischer Heilkunde von Hufeland*, July, 1821.)

Globules, and balls of fat, discharged from the rectum, are noticed in various medical collections of high authority, both domestic and foreign.*

Thus, in the Edinburgh Medical Essays, we have an instance of a whitish substance like tallow or hardened marrow, being a congeries of globules, passed among the excrement, the entire mass making the size of a walnut; other masses having been passed several days afterward of the size of so many peas.—(Vol. i., part. ii., art. lxvi., p. 145.) The Paris Academy of Surgery have published similar accounts.—(See especially *Hist. de l'Acad. Royale de Chir.*, iii., p. 14.) So Dietrich gives the case of a waxy mucous matter—*materia ceracea mucosa*—passed by the rectum, weighing more than an ounce (*Observations*, &c.); and Paulini notices several instances that had fallen within the range of his observation (Cent. i., obs. 15); in one of which the concretions were of a green hue. Vander Wiel describes a case of the same appearance (*Stalpart Vander Wiel*, cent. i., obs. 61); and Zeller has found them loaded or covered with hairs (*Dissert. Molæ viriles memorab.*, Tubing, 1696), probably swallowed

accidentally. So in the *Acta Naturæ Curiosorum* (vol. iii., obs. 51), we have an instance very like the first of Dr. Babington's cases; the concretions were dejected in a paroxysm of colic, and are described as "excreti globuli, quasi saponacei, cedente dolore hypochondriorum." And I suspect we are to refer to the same species a case ascribed by Dr. Scott, of Harwich, Roxburghshire, to hydatids, or something resembling them.—(*Edin. Med. Comm.*, vol. v., p. 183.) The patient had for many months been occasionally subject to colic and dyspeptic affections, accompanied with great pain and faintness. He at length "began to void by stool substances of a brown colour, some about the size of nuts, and some as big as walnuts, which were bags that contained matter of a yellow hue like pus, besides a great many empty ones that had broken. I have seen eight or ten passed in one stool." This continued for eight or ten days, and the patient then recovered.

In all these cases we find proofs of morbid intestinal action, commonly accompanied with pain and *coprostasis obstipata*, or costiveness from weakness and torpidity in the vermicular movement of the intestines.

It is under like circumstances that the substance called *ambergris* is found in the larger intestines of the cachalot, or spermaceti-whale (*physeter macrocephalus*, Linn.), which generally contains sixty per cent. of fat, and is never higher up than six or seven feet from the anus. It appears to be more completely elaborated in proportion as the animal is more sickly and affected with costiveness, and does not dung on being harpooned; and hence the most valuable, according to the report of the South Sea whalers, is that which is extracted from animals that have died of the complaint. It is found in masses of from fourteen to more than a hundred pounds weight; and appears at first to bear a close resemblance to the feces of the whale, but hardens on exposure to the air. The largest lumps have probably not been discharged, but separated from the body of the animal during the process of putrefaction after death. Neumann gives an account of one mass found on the coast of the Island of Tidor, that weighed not less than a hundred and eighty-two pounds.—(*Phil. Trans.*, vol. for 1734.) It was purchased of the King of Tidor, by the Dutch East India Company, in 1693, for eleven thousand dollars, and measured five feet eight inches in thickness. It was long exhibited at Amsterdam, and at length broken up and sold. Other masses of many pounds weight have been found floating on the sea: and the concretions, thus detached and of different bulks, are carried into every quarter by the tides and currents, and have sometimes been found on the shores of the West Indies; whence Waller:

"Bermuda wall'd with rocks, who does not know
That happy island where huge lemons grow?
Where shining pearl, coral, and many a pound,
On the rich shore, of AMBERGRIS is found."

* In the last volume of the Medico-Chirurgical Transactions, Professor Elliotson has published a valuable paper, containing all that is at present known respecting the discharge of fatty substances from the bowels. The reader will find an abstract of it in the present work, at the conclusion of the section on diarrhœa.—Ed.

Sometimes, however, it is traced in great abundance in the intestines of whales that are harpooned, and which, probably, would soon

have died of an obstruction in the bowels, if they had not been taken. A captain in the Southern Whale Fishery, examined before the privy council in 1791, related, that he had found three hundred and sixty-two ounces of this substance in the intestines of a female, struck off the coast of Guinea; part of which was voided from the rectum on cutting up the bladder, and the remainder traced in the intestinal canal.—(*Phil. Trans.*, vol. lxxi.) The mass is usually loaded with hard bony fragments, by the seamen called squids, which are the beaks of the cuttle-fish, on which the whale is known to feed.

When recently taken, the smell of ambergris is very strong, and rather fetid, but by keeping the offensiveness goes off, and it acquires a faint musky odour. It has scarcely any taste. Its colour is ash-gray, or brown, somewhat mottled: its hardness is sufficient to render it easily friable, but not to bear a polish; when broken down it has a soapy feel like stearite.

Sir Everard Home has endeavoured to account for the production of all these varieties of scybala, and to show that, while it is the office of the stomach and intestines to furnish nutriment for the muscles and membranes out of the finest part of the food, which is separated from the rest for this purpose, it is in like manner the office of the larger intestines, and especially of the colon, to convert a considerable part of the refuse matter into fat, by combining it with the bile, and to send it, thus changed in its nature, by channels of which we know nothing, into the circulation, and deposite it in almost every part of the body, to lubricate the whole, and especially to promote the growth of the animal frame in youth.—(*Phil. Trans.*, 1813, art. xxi.)

It is unquestionable that, with all our advances in the knowledge of physiology, we are, to this hour, in great ignorance of the means by which the fat of the different parts of the body is produced, or the quarters from which it is drawn. But it militates against the hypothesis before us, that we have no instance of the existence of fat in the larger intestines when they are in a state of health; and that to produce scybala of every kind, and particularly those that are more oleaginous, a weak and diseased condition of the intestinal canal appears to be indispensable. While in the second case related by Dr. Babington, in which the fatty material seems to have been elaborated in its most perfect state, the bile does not appear to have been at all transformed from its natural to any new character, nor indeed to have been in any degree operated upon; for we are expressly told, that the material when voided had “an unusually yellow tinge,” notwithstanding that it was “quite fluid like oil.”

The subject, however, is worth pursuing: and Sir Everard has endeavoured to support his views by a later article inserted in the same work, on the transmutation of the tadpole into a frog (*Phil. Trans.*, 1816, p. 301), in which, after showing that the intestines of the tadpole are much larger and more complicated than

those it possesses in its frog state, he argues, that this more extensive and elaborate machinery is for the purpose of forming a larger abundance of oleaginous matter as food, at a period when the animal is less capable of obtaining food from without; and he observes further, that the intestinal canal of the tadpole is surmounted with, and, in some species, imbedded in fat.

GENUS XI.

HELMINTHIA.

INVERMINATION. WORMS.

WORMS OR LARVÆ OF INSECTS, INHABITING THE STOMACH OR INTESTINES.

THE subject of our last genus, I observed, was new, or nearly so, to the science of pathology: that of the present is equally new to nosological arrangement; for, it is a singular fact, that while almost all systems contain a distinct genus under the name of phthiriasis, or malis, or cocyta, and some of them two distinct genera, for the purpose of arranging such insects, larvæ, or vermicles as are occasionally found infesting the surface of the body, and which, to avail ourselves of a significant term derived from old English botany, may be called animal *doadders*, few or none of them comprise any division whatever for intestinal larvæ or worms, notwithstanding the infinitely greater mischief they often produce, and the far greater difficulty of getting rid of them.*

Dr. Cullen, indeed, in the latter part of his life, was sensible of the importance of this omission, and would most probably have corrected it in his own system, had he found leisure or inclination for a revival of it, since he has introduced the term *VERMES* into his “*Catalogus Morborum, a nobis omissorum, quos omisisse fortassis non oportebat.*”

In many instances, however, physiologists and pathologists have abundantly supplied the deficiency; for there is scarcely a disease of any

* Every kind of animal has its *entozoa*, or internal parasites, which are peculiar to itself, just as it has its *ectozoa*, or external ones. The number of species of *entozoa* is therefore considerable, and their study constitutes an important branch of zoology. Cruveilhier thinks it more practically useful to divide the *entozoa* of the human race, as Linnæus did, according to the situations which they occupy: first, into such as are developed in cavities communicating with the external air (intestinal worms); and into others, which lie imbedded in the very substance of organs (visceral worms). This division seems to Cruveilhier more advantageous to the physician than that of Rudolphi, who very scientifically distinguishes *entozoa*, by the varieties of their form, into *nematoides*, *oceanthocephala* (found chiefly in the intestines of swine), *trematoda*, *cestoides*, *tæniæ*, or tape-worms, and *cystica*, or hydatids.—(*Entozoorum sive Vermium intestinalium Historia*. Amstel., 3 vols., 8vo., 1808, fig., and *Entozoorum Synopsis* Berol., 1819, 8vo.) Cruveilhier also prefers the division adopted by Linnæus to that proposed by Cuvier, who arranges *entozoa* into two classes; one characterized by a digestive cavity (*entozoa cavitaires*), and another by their *parenchymatous* structure.—Ed.

kind which has not been referred by some of them to vermination as its origin. This is particularly true of the school of Linnæus, though it is not confined to that seminary. Thus, Linnæus himself laboured hard to prove, that dysentery is the effect of a peculiar larva or grub belonging to the acarus or tick genus, which he has ventured to introduce into his Natural History under the name of *acarus dysentericæ*. So Kircher has ascribed the plague to another kind of animalcule; Langius, the measles; various authors, the itch; Siggler, petechiæ; Lusitanus and Poncellus, smallpox; Dessault, lyssa, or canine madness; Hauptman, syphilis; Martin and Udman, both pupils of Linnæus, elephantiasis; and Nyander, another pupil of the same great teacher, contagious diseases of most, if not of all kinds. Some, again, have ascribed piles to the same source; others, the inspissated and vermiform mucus squeezed out occasionally from the excretory ducts of the small mucous glands of the forehead, in the present system described under the genus and species *ionthus varus*; and others again, the toothache: which last opinion seems at one time to have been adopted generally; for we find Shakspeare making one of his best-drawn characters exclaim—

“What! sigh for the toothache!

Which is but a humour or a worm.”

It is not very wonderful, therefore, to behold the extensive use to which the *tania hydatidis*, or hydatid, is applied in modern times, so as to be regarded as the parent of almost every limpid cyst discoverable in the body; nor that cancer of the breast should be ascribed to a similar generation; and the less so, since it is not a century ago, that it was gravely argued by the most enlightened physiologists of the day, and supposed to be ocularly and irrefragably demonstrated, that man himself is, in every instance, the progeny of a similar kind of maggot, which, it was said, might be seen by any one who would take the pains to look for it, vivaciously frolicking in the vast ocean of a drop of male semen.

We are, at length, approaching to more sobriety in our observations and inquiries; and it is high time such a period should arrive; for we were in great danger of running into the wildest fancies of equivocal generation, and of equally relinquishing all principles and all limits in natural history. We now know, that an incipient stage of putrefaction, or a very short quiescence and exposure of animal fluids to a warm atmosphere, is sufficient to load them with animalcules of some kind or other; not, indeed, by fortuitously converting the constituent and decomposing principles of such fluids into the simple forms of microscopic life (for of this we have no proof whatever), but rather by affording to some few of the myriads of invisible ovula with which the atmosphere swarms, and which it may convey to them, the proper nidus, or the quickening stimulus they stand in need of. [The hypothesis of worms being the product of putrefaction only proves, that the believers in it had never examined the generative organs of those animals.—(Merat, in *Dict. des Sc. Méd.*, tom. lviii., p. 215.)]

That the atmosphere is freighted with myriads of insect-eggs that elude our senses, and that such eggs, when they meet with a proper bed, are hatched in a few hours into a perfect form, is clear to any one who has attended to the rapid and wonderful effects of what, in common language, is called a blight upon plantations and gardens. I have seen, as probably many who may read this work have also, a hop-ground completely overrun and desolated by the *aphis humuli*, or hop green-louse, within twelve hours after a honey-dew (which is a peculiar haze or mist loaded with a poisonous miasm) has slowly swept through the plantation, and stimulated the leaves of the hop to the morbid secretion of a saccharine and viscid juice, which, while it destroys the young shoots by exhaustion, renders them a favourite resort for this insect, and a cherishing nidus for the myriads of little dots that are its eggs. The latter are hatched within eight-and-forty hours after their deposit, and succeeded by hosts of other eggs of the same kind; or, if the blight take place in an early part of the autumn, by hosts of the young insects produced viviparously; for, in different seasons of the year, the *aphis* breeds both ways.

Now it is highly probable, that there are minute eggs, or ovula, of innumerable kinds of animalcules floating by myriads of myriads through the atmosphere, so diminutive as to bear no larger proportion to the eggs of the *aphis* than these bear to those of the wren, or the hedge-sparrow; protected at the same time from destruction by the filmy integument that surrounds them, till they can meet with a proper nest for their reception, and a proper stimulating power to quicken them into life; and which, with respect to many of them, are only found obvious to the senses in different descriptions of animal fluids. The same fact occurs in the mineral kingdom; stagnant water, though purified by distillation, and confined in a marble basin, will in a short time become loaded on its surface or about its sides with various species of confervas; while the interior will be peopled with microscopic animalcules. So, while damp cellars are covered with boletuses, agarics, and other funguses, the driest brick walls are often lined with lichens and mosses. We see nothing of the animal and vegetable eggs or seeds by which all this is effected; but we know that they exist in the atmosphere, and that this is the medium of their circulation. How far the tales may be true, of living animals found in abscesses in different parts of the body, and especially in scirrhus and pustulous exanthems, this is not the place to inquire; but, conceding the fact, we can only account for it by supposing their respective ovula to have been admitted into the system with the air or food we take in; and to have been separated as soon as they acquired possession of a proper nursery.

We have strong reason to believe, however, that many of the eggs or animalcules that are traced in animal fluids, occasionally find other receptacles out of the body that answer their purpose as well, and seem to keep up their respective species; and consequently, that provide

a stock of eggs, larvæ, or insects, prepared to take possession of any decomposing animal substance as soon as it is ready for their reception. And we are hence able to account for the presence of animalcules in such situations, without being driven to the necessity of supposing them to have been generated therein; and see how it is possible that they should continue to exist in a regular chain of succession, instead of being produced anomalously and equivocally by the *bildungstrieb* (as the German physiologists call it), or formative effort of a living principle, in substances in which life has confessedly ceased to exist.

Thus Rolander, who, like Linnæus, ascribed dysentery to the dysentery-tick, or *acarus dysentericæ*, and who himself laboured under this disease while residing in Linnæus's house, contended that he had discovered the same insect in a water-vessel made of juniper-wood; and conceived that it was conveyed in great numbers into his body by the water which he drank from the cistern. So Lister affirms, that he has seen the *ascaris vermicularis* (the maw or thread-worm), which is usually found burrowing in the lower part of the intestines, infesting the surface as well. In like manner Palmærus has rendered it at least probable, that the young or ova of the *fasciola hepatica*, or fluke, found so abundantly in the liver of sheep that die of the rot, and the origin of which has so much puzzled the naturalists, are swallowed by the sheep in marsh or stagnant waters. And Linnæus himself pointed out, that the *tania solium*, or tape-worm, the cause of whose existence in the alvine channel has been a source of equal difficulty to the physiological inquirer, exists, though much smaller, in muddy springs; and notwithstanding that Pallas at first expressed doubts upon this point, the assertion has been since confirmed by additional and satisfactory observations.*

[The *ascaris vermicularis*, which is usually considered peculiar to the human body, is alleged by Dr. Barry, of Cork, to be derived from without; as worms, differing from it merely in colour, were traced by him, in one instance, to the well of a particular country-house, two miles from Cork, where the whole family, and every other person that drank the water, invariably became afflicted with ascarides.† One argu-

ment, with which all statements of this kind are generally met, is, that intestinal worms cannot live out of the body, and therefore they must differ from worms, more or less resembling them, found elsewhere: yet, it is possible to conceive, that an animal that is hatched and attains its growth in a particular temperature, unexposed to the air, may not be able to sustain the sudden removal from its warm sheltered nursery, though it might have thriven in a much colder and more exposed situation, had it never been made too tender by the influence of habit, &c. Worms of the human intestines die, not only soon after their discharge from the body, but frequently even before they are voided, when the health of the individual is much disordered by fevers. They also invariably perish with the patient; when the supply of their wonted nutriment may be supposed to cease, and the temperature to which they are accustomed is rapidly lessened.

Some writers state that worms never meddle with the alimentary matter in the bowels, but derive their nutriment by suction from the substance, or vessels of the viscera; while others represent those worms which occupy the small intestines, as feeding on the chyle itself. The editor is not aware that any decisive evidence, exclusively supporting either of these opinions, is on record.]

Is it not surprising, that doubts should at times exist in the mind of the precise and cautious inquirer in many cases of this kind, which can only be removed by a long and attentive investigation of the history of the minute animals which give rise to them? for, first, the very same species assumes so different an appearance in different stages of its existence, that nothing but the most patient prosecution of the same individual through all his metamorphoses, could induce us to put any faith in its individuality. For who, for example, if he did not know it by the repeated experience of himself or of others, could believe that the black and the white carrion vulture of America (*culture aura*, Linn.), which, when teased, emits a cry like a mouse, are the same bird, merely changing from white to black as it grows old? Who could divine that the tadpole, possessing gills and a fish-tail, and without legs, should be the same animal, only younger, as the four-legged frog that has neither tail nor gills? or that a like identity should apply to the caterpillar, the aurelia, and the winged moth? But, secondly, we often see an almost equal change produced in a few generations of the same species, and occasionally in the same individual, by a change of food or habitation, or both. How widely different is the domestic sheep from the argali; or the ox from the bison! yet these are the stocks from which they have proceeded. A difference of food alone produces a growth and development of sexual organs

* This statement disagrees with the observations of Bremser, Rudolphi, and Cruveilhier.—Ed.

† Barry on the Origin of Intestinal Worms; see Trans. of the Association of Physicians, &c.—Ireland, vol. ii., p. 389. It was the opinion of Linnæus, that intestinal worms were merely terrestrial or aquatic ones, swallowed either completely formed, or in the state of ova, or germs. But, against this doctrine, it is argued, that, if it had a good foundation, worms precisely similar to those met with in the human alimentary canal, would also be found out of it; as indeed Linnæus and others maintain is actually the case. But if, as Bremser has done, who devoted twelve years of his life to the study of entozoa, we strictly inquire into the facts brought forward, we shall find them to be vague, carelessly observed, and generally adduced by persons unacquainted with helminthology. Hence, Cruveilhier lays it down as an axiom, that worms, like intestinal

worms, have never been met with out of the bodies of man and other animals, unless discharged from them. And another proposition which he considers completely established, is, that no terrestrial or aquatic worms have ever been met with alive, in the bodies of men and other animals, unless they had been very recently introduced into them.—Ed.

in the honey-bee, and converts what have hitherto been called neuters (but which are really imperfect females) into queens, or bearing bees. In many instances we can trace changes as considerable (and shall presently have occasion to remark them) in worms, or the larvæ of insects, introduced accidentally into the human intestines from without. Several of these, however, are animals with the whole of whose history we are acquainted; but we are not acquainted with the whole of the history of the ascarides, the tæniæ, and various other intestinal worms; and hence might not know them out of the body, even though we should actually meet with them under some form or other.*

* These remarks, however ingenious, are not in agreement with what is now taught by some of the best pathologists. It has often been suspected (and Boerhaave himself entertained the opinion) that when aquatic or terrestrial worms pass into the alimentary canal, the new medium in which they live, and their entirely novel condition, may account for their metamorphoses, not more extraordinary than those of the tadpole and insects. In refutation of this notion, while Cruveilhier admits the influence of external circumstances on every thing that has life, he joins M. Edwards in declaring such influence to be subordinate to the omnipotent action of race and species. The view which he takes of this subject, is supported by various considerations:—

1. The structure of intestinal worms has not the most distant resemblance to that of worms which live in the earth or water. 2. Why are not the same kinds of worms met with in all the species of animals, and why, on the contrary, has each species intestinal worms which are peculiar to it? 3. Why, in the same animal, does the same kind of worm constantly dwell in one particular part of its alimentary canal? 4. How does it happen, that the intestinal worm perishes almost as soon as it is voided from the alimentary canal, just as the terrestrial or aquatic worm dies immediately it has entered the digestive tube? 5. How, in the hypothesis professed by Boerhaave, and to which our author inclines, would it be possible to account for the almost interminable reproduction of intestinal worms, if the animal's body within which they multiplied were not the medium they were destined for? But in the same manner as certain larvæ of insects, introduced into the alimentary canal of certain animals, find here alone the only requisites for their development, why should not human intestinal worms proceed from the introduction of particular germs into the alimentary canal, which in any other situation could not thrive? This question suggested itself to Cruveilhier by a case, in which a very large caterpillar was alleged to have been voided with the feces, and on which occurrence both Cruveilhier and M. Jules Cloquet were consulted. The latter communicated his opinion of the circumstance in a note:—"The animal shown me is the caterpillar of a moth, perfectly developed, and ready to be transformed into a chrysalis. If it has been discharged *alive* by vomiting, it must have been swallowed by the patient immediately before its ejection. If really swallowed, its magnitude prevents us from supposing that this could have happened inadvertently; nor could this have taken place when the larva was but of trivial size, because its organization would have formed an impediment to its living and growing in the intestinal canal." (See Dict. de Méd. et de Chir. Pratiques, art. ENTÉROZOAIRE.) Cruveilhier considers this the most ra-

As animalcules are parasitic to plants, so are plants at times parasitic to animals. As I have seen, fungi spring up night after night on the sheets of patients with gangrenous limbs, where the corrupt discharge has soaked into the sheets, and rendered them a quickening nidus. Several species of clavaria grow on the chrysalis of one or two species of cicada, and even on the perfect insect itself, as others do on the May-fly.* Were this indeed the proper place for pursuing so interesting a study, I could show not only that there is scarcely an animal of any class or order, from the highest to the lowest, but is a prey to other animals of a minuter form that infest its interior as well as its surface, but that there is scarcely a vegetable which has not also its parasitic plunderers, and is infested in like manner. But the subject would carry us too far: yet a few additional hints in relation to it are given in the comment to the Nosological System, and those who are desirous of extending the study may turn to them at their leisure.

[Worms are said to prevail in the greatest degree among the poor, dirty, ill-fed classes of society, and particularly in persons who reside in damp, marshy countries. According to M. Fortassin, the tænia is very frequently met with in butchers and others who deal in new-killed animal substances. Persons in the habit of taking a good deal of wine, and other spirituous liquors, are rarely afflicted with worms. Infants also, while they take no other food but their mother's milk, seldom have them. These circumstances, having a close reference to the causes of worms, a subject that is yet very obscure, seem well-deserving of the reader's attention; but stand in need of further confirmation.]

The various kinds of worms traced in the human stomach and intestines, have been differently arranged by different writers: but they have been chiefly assorted into *round* and *flat* worms; or into *indigenous* and *exotic*: in other words, into those which we are told are *generated* in the alvine channel, and those which enter it *from without*. The first method is too limited; and the second, as we have already seen, not only hypothetical, but built on a false basis; for we have reason to believe that every species found in this channel, primarily existed out of it.† In unfolding, therefore, the subject

tional explanation which the case admits of, and the only circumstance that rather shakes his confidence in it, is what happens in the horse with respect to the ova of the cestrus or common gadfly; a subject hereafter touched upon. Dr. Eliottson once saw two centipedes, said to have been vomited by a girl twelve years of age; the animals had lived three days when he saw them. If they were truly swallowed, and lived any considerable time in the stomach, the fact is curious; because these insects one would not expect to be capable of living long in the fluids of the stomach.—Ep.

† Some of the facts and arguments brought forward by Bremser (Traité Zoologique et Physiologique sur les Vers Intestinaux de l'homme, avec

further, we shall employ a different arrangement, and comprehend, under the genus *HELMINTHIA*, three species of diseases, equally distinguished from each other by symptoms, and by the different tribes of animals which give rise to them; viz. those which are nourished and find a proper habitation throughout every part of the alvine canal; those whose proper habitation is limited to the extremity of the canal; and those which have no proper habitation in any part of it, and enter it erroneously or by accident.

SPECIES I.

HELMINTHIA ALVI.

ALVINE WORMS.

WORMS EXISTING AND FINDING A PROPER NIDUS IN THE STOMACH OR ALVINE CANAL, CHIEFLY OF CHILDREN AND SICKLY ADULTS; PRODUCING EMACIATION, A SWELLED HARD BELLY, GNAWING OR PUNGENT PAIN IN THE STOMACH, PALE COUNTENANCE, FETID BREATH, AND IRRITATION OF THE NOSTRILS.

THE worms that chiefly infest this region, and produce these symptoms, may be arranged under the following varieties:—

- | | |
|---------------------------------|-------------------|
| a <i>Ascaris lumbricoides</i> . | Long round-worm. |
| β <i>Trichocephalus</i> . | Long thread-worm. |
| γ <i>Tænia solium</i> . | Long tape-worm. |
| δ <i>Tænia vulgaris</i> . | Broad tape-worm. |
| ε <i>Fasciola</i> . | Fluke. |

[So common are certain worms in the human subject, that it is calculated one half of the total number of children have either the round or thread-worm. *Tænia* is more rare, however; so that an estimate has been made, that in France, only one individual in a hundred suffers from it.—(*Diet. des Sciences Méd.*, tom. lviii., p. 215.) Worms are often only of one kind, and most frequently of the long round species; yet it is not very uncommon to find two species existing together in the alimentary canal. The records of medicine furnish examples of patients who even voided simultaneously *ascarides*, *tæniæ*, and *lumbricoides*. Generally speaking, the smaller the worms, the more numerous they are; and the *tænia*, the largest, has received the epithet of *solium*, from the supposition that it is always solitary, which was the notion of Hippocrates; but this is a mistake, for in the human subject several may be met with together; and in animals, and especially in the canine race, tape-worms sometimes exist together in great numbers. It was Bremser's belief that an entire tape-worm had never been seen, as the caudal articulations, which are loaded with fecundated ova, break off, and are discharged, before the complete development of the joints towards the head.]

The head of the LONG ROUND-WORM is slightly

des notes de Blainville, Paris, 1824, 8vo.) and by Cruveilhier, against the side of the question taken by Dr. Good, have been adverted to in the preceding notes.—ED.

incurved, with a transverse contraction beneath it; mouth triangular; body transparent, light yellow, with a faint line down the sides; gregarious and vivacious; from twelve to fifteen inches long: inhabits principally the small intestines of thin persons, generally about the ileum, but sometimes ascends into the stomach, and creeps out of the mouth and nostrils; occasionally travels to the rectum, and passes away at the anus. Frank notices an instance of eighty of these worms rolled up into a ball, and expelled during a fever; and gives another case, in which the whole intestinal canal, from the duodenum to the rectum, was crammed with them.—(*De Cur. Morb. Hom. Epit.*, tom. vi., lib. 6.)

[They sometimes quit the alimentary canal and lodge in some adjacent part. MM. Andral and Blandin met with one example, in which a long round-worm had insinuated itself into the cavity of the larynx, and lay between the two chordæ vocales. The patient, a child, had been suddenly seized with extreme difficulty of breathing, and very shortly died of suffocation. M. Andral was shown, by M. Guersent, a liver that had been, as it were, pervaded in different directions by long round-worms, which had passed from the duodenum into the liver, through the ductus choledochus. Andral was acquainted with only one additional fact of this kind; it is recorded in the Bulletins de la Faculté de Méd. de Paris.

Long round-worms, in a few rare cases, pass through a perforation in the bowels, get into the peritoneum, and either remain there, or are discharged through a cutaneous fistula, or insinuate themselves into the bladder or vagina.

With regard to the questions whether these worms can only pass from the intestines into another organ, through an accidental opening already existing? or whether they sometimes form the passage themselves? M. Andral is of opinion, that if the latter case ever takes place, it must be extremely rare. As the *ascaris lumbricoides* cannot live out of the alimentary canal, it is fair to presume that even if it had the power of perforating the coats of the intestine, and getting out of it, the instinct of self-preservation would hinder it from doing so. Yet the same author conceives that this may not be the case after the death of the animal in which an *ascaris lumbricoides* is developed, and that the latter may then have a greater inclination than during life to make its way through the parietes of the bowels.* The disturbance of the constitution by a severe attack of fever seems to extend its effects to these inhabitants of the digestive canal, as the frequency of their evacuation during such illness is well known.†]

* Précis d'Anat. Pathol., t. ii., p. 181. Cruveilhier joins Rudolphi and Bremser in rejecting the opinion that intestinal worms ever form the perforation themselves, and believes that when they pass through the coats of the bowels, it is in consequence of an aperture having been first produced by ulceration.—See *Diet. de Méd. et de Chir. Pratiques*, art. ENTÉROZAIRES.

† Dr. Gaspard mentions an epidemic remittent

This animal will sometimes remain so quiet in its proper region, as to give no signs of its existence but by its discharge. Frequently, however, it is a troublesome and mischievous intruder, producing an intolerable feeling of faintness, great emaciation, and most of the symptoms enumerated under the specific definition. In its general appearance it bears so striking a resemblance to the earth-worm (*lumbricus terrestris*, Linn.), that by many naturalists it has been regarded as the same. Yet, to an attentive observer, there is a considerable difference both in their form and movements.* The body of the intestinal worm is round, its colour is a pale red, its head is furnished with three vesicles placed triangularly, and, in moving, it curls its body into circles, from which it extends its head. The earth-worm is flat towards the tail, and has bristles on its under side, which it can erect at pleasure. Its colour is dusky red; its head has but one vesicle, and it moves by a continuous course of action propagated from ring to ring.

[Morbid anatomy throws no light on the causes of the formation of the ascaris lumbricoides, which occurs in every possible organic condition of the bowels: they may be red or pale, dry, or full of mucous secretions. Around the places in which many worms collect, the intestine is frequently red, while the group of worms itself is often enveloped in a mass of mucus (*Andral*, vol. cit., p. 183); but these appearances are to be entirely referred to the worms' acting as foreign bodies, and have nothing to do with their production.]

The body of the LONG THREAD-WORM is elastic and contorted, the hinder part thick, the anterior capillary twice as long as the thick part, and terminating in so fine a point, that the mouth is scarcely discernible; its upper surface subrenated; its lower smooth; it sucks with its small capillary extremity; is from an inch and a half to two inches in length; finely striate on the fore part: in colour resembles the preceding; gregarious, and found chiefly in the intestines of sickly children; generally in the cæcum. Roederer and Wagler found a large quantity of trichocephali in the colon. They are found also in many animals besides man, as the horse, boar, fox, and mouse. The male may be distinguished by the curved shape of its posterior extremity. In its slender body a straight alimentary cavity is seen, with spermatic vessels, or oviducts, around it.

In the LONG TAPE-WORM the articulations are long and narrow, with marginal pores by which it attaches itself to the intestines, one on each joint, generally alternate; ovaries aborescent;

and intermittent fever that occurred in France in 1826, with peculiar severity. The discharge of living intestinal worms, with copious quantities of bile, was a common occurrence in it. In one case, true caterpillars were also voided, both from the stomach and rectum.—Magendie, *Journ. de Physiol.*, tom. ix., p. 230.

* See Baillie's *Morbid Anatomy*, Hooper on *Intestinal Worms*, *Mem. Lond. Med. Soc.*, vol. v.; and Bremser's *Treatise*, already referred to.

head with a terminal mouth surrounded by two rows of radiate hooks or holders; and a little below, on the flattened surface, four tuberculate orifices or suckers, two on each side; tail terminated by a semicircular joint without any aperture; from thirty to forty feet long, and has been found sixty. Inhabits the intestines of mankind, generally at the upper part, where it feeds on the chyle and juices already animalized. It has also been found in the stomach;* is sometimes solitary, but occasionally in considerable numbers; and adheres so firmly to the intestines, that it is removed with great difficulty. [It is seldom met with in France, where the broad tape-worm prevails; but it is common in Italy and Saxony—(*Merat, in Dict. des Sc. Méd.*, tom. lxvii., p. 227.) While the ascaris lumbricoides, the trichocephalus, and ascaris vermicularis, are most common in children, the tænia is chiefly noticed in adults.] The animal is oviparous, and discharges its numerous eggs from the apertures on the joints. Werner asserts that it is hermaphrodite. The broken-off joints have, when discharged, the appearance of gourd-seeds: and it is hence denominated gourd-worm by many medical writers; and is the *lumbricus cucurbitinus* of Dr. Heberden. Dr. Sibbargaard gives the case of an adult female patient, who was infested with a tape-worm of enormous length, meas-

* Since this sheet was sent to press, the editor, through the kindness of Mr. Docker, formerly an eminent surgeon at Canterbury, has been informed of an extraordinary case, now under the care of Mr. Law of Penrith, Cumberland, in which the bladder is the seat of tænia. The patient is a young woman, about twenty years of age, and first felt a sensation, like a rupture of the bladder, when in the act of stooping to cut corn, in August, 1829. After this, she began occasionally to have discharges of bloody urine, with the sensation of something moving in the bladder, more particularly after each evacuation. In October, 1830, some consideration of the symptoms led Mr. Law to try turpentine both by the mouth and in injections. Great irritation ensued, but eight joints of a tænia were discharged from the meatus urinarius *alive*. Opiate injections were then tried, which, having been persevered in for three days, seemed to put an end to all motion of the worm; and by an expansion of the meatus, its discharge was effected in large quantities; but in so decayed and broken a state, that its parts could not be numbered; but Mr. Law is certain that there could not be less than two thousand joints. With these there was much hemorrhage, and discharge of membranous and other substances, like pieces of liver. A period of tranquillity now followed, and lasted until January, 1831, when she began to suffer again, and voided, with the aid of turpentine, in the course of eight or nine months, one thousand two hundred and thirty-nine joints; and, subsequently, an immense number of others. Mr. Law has in his possession one portion, consisting of twenty-nine joints. As this case will, no doubt, be published before the completion of this edition, the editor will merely add, that he has examined some of the portions of tæniæ voided, and that no doubt can be entertained of the facts above specified. Drs. Elliotson and Carswell have also examined the specimens, with the reality of which they are entirely satisfied.—Ed.

uring not less than thirty-eight yards, or one hundred and fourteen feet. It was expelled from the anus, after three doses of a bolus, consisting of two drachms of tin filings and half a drachm of jalap mixed up with honey, had been taken.*

The articulations of the BROAD TAPE-WORM (bothriocephalus) are short and broad, with a pore in the centre of each joint, and stellate ovaries round them; body broader in the middle, and tapering towards both ends; head resembling the last, but elongated, marked with two lateral depressions, and not provided with a neck; tail ending in a rounded joint. [The anterior joints are like plaits, but the posterior ones are very distinct. The apertures, which in the long tape-worm are situated at the edges of the articulated parts, here lie in their centre. These peculiarities in the bothriocephalus, certainly justified Bremsen in setting it down as a particular genus. But, as an additional reason for doing so, it may be observed, that it infests almost exclusively the Russians, Poles, Swiss, and the natives of certain parts of France; while the long tape-worm resides in the small intestines of other Europeans and the Egyptians.†] Like the last, it inhabits the upper part of the intestines, and feeds upon chyle; generally from three to fifteen or twenty feet long; usually in families of three or four. [Rudolphi had a specimen, the rings of which were an inch in breadth. Boerhaave assures us that he succeeded in discharging a worm of this kind from a Russian, that measured three hundred ells!]

The body of the FLUKE is flattish, with an aperture or pore at the head, and generally another beneath; intestines flexuous; ovaries lateral; hermaphrodite, and oviparous.‡

Of all intestinal worms, this is one of the most common to animals of different classes. It is sometimes, though rarely, found in man (*Docver, Verm.*, p. 54; *Clerk, Lumbric.*, p. 119);

* Societatis Medicæ Havniensis Collect., vol. ii., 8vo. Van Doeveren mentions an instance in which a portion of tænia was voided, 150 feet long; and Rosenstein records a case in which a tænia 300 feet in length was discharged from the bowels. Cruveilhier suspects, that some of these calculations have been made either by adding together the lengths of pieces of different worms, or taking the aggregate lengths of portions of one worm discharged at different periods. The longest in Bremsen's possession was twenty-four feet, who however quotes an instance where a tænia was found in the dead subject, reaching from the pylorus to within a few inches of the anus, and measuring thirty feet.—Ed.

† Cruveilhier, art. ENTOZOAIRIES in Dict. de Méd. et de Chir. Pratiques.

‡ C. A. Rudolphi's works, entitled, Entozoorum sive Vermium Intestinalium Historia Naturalis, Amst., 1808, and Entozoorum Synopsis, Berol., 1819, should be consulted by all who desire the most correct description of intestinal worms. Nor should the writings of Bloch, Goeze, Zeder, Werner, Hermann, Fischer, Brera, Hooper, Lamarck, Dumeril, Cuvier, Blumenbach, Bremsen, Laennec, and Cruveilhier (Dict. de Méd. et de Chir. Pratiques, art. Entozoaïres) be forgotten.—Ed.

but in different species, or under different modifications, we meet with it very frequently and very abundantly in quadrupeds of almost all kinds, reptiles, fishes, and even in worms themselves of a larger growth, for it is occasionally met with in the intestines of the cuttle-fish. Its ordinary seat is in the stomach or alvino channel; but in swine, black cattle, deer, and sheep, its favourite haunt is the liver, to which it probably creeps forward through the bile-ducts, and where it burrows and breeds in innumerable hosts. This is particularly the case with the *fasciola hepatica*, as it is called by way of emphasis, found so commonly and so abundantly in the liver of sheep that labour under the disease called the rot; though whether it be the cause or the effect of this disease, has not yet been ascertained. Most probably the effect: for the rot is certainly an infectious complaint, and is sometimes caught by a whole flock in a single night. The cause has been supposed to be hydrogenous gas; but of this we have no proof. There can be little doubt, however, that it is produced by some deleterious miasm in the atmosphere originating in the pasture itself, or conveyed there in the form of a haze, in the same manner as vegetable plantations are often blighted, of which I have just offered an example from hop-grounds. Yet by what means the liver of sheep, rather than any other organ, is hereby affected and rendered gangrenous, we have still to inform ourselves. As the animal is oviparous, the minute eggs may be borne by the haze itself, or exist in the stagnant atmosphere of the sheep-ground; or they may already, in the body of the parent-worm, be infesting the alimentary canal, and only waiting for accidental circumstances to exert the full range of their prolific powers; for it is not in the rot alone, but in other cases of visceral diseases, that this animal is traced in sheep, and especially in dropsy, whether connected with the rot or not; and, in both diseases, they are frequently found vomited up in brooks.

As the treatment of all the species should be established on the same principle,—that of invigorating* the alimentary canal and surrounding viscera,—and the vermifuges adapted to many of the different tribes, though not to all, are the same,—it will be better to reserve this subject till the nosological characters of the remaining species have passed in review before us.

SPECIES II.

HELMINTHIA PODICIS.

ANAL WORMS.

WORMS, OR THE LARVÆ OF INSECTS, EXISTING AND FINDING A PROPER NIDUS WITHIN THE VERGE OF THE ANUS, EXCITING A TROUBLESOME LOCAL IRRITATION, SOMETIMES ACCOM-

* This expression seems to be connected with an hypothesis entertained by some writers, and adopted by Dr. Good, that the production of worms is referable to a debilitated state of the alimentary canal.—Ed.

PANIED WITH TUMOUR; FREQUENTLY PREVENTING SLEEP; AND PRODUCING PAIN OR FAINTNESS IN THE STOMACH.

UNDER this species are included the following varieties :—

α	Ascaris Vermicularis.	Thread-worm.
β	——— Scarabæus.	Maw-worm.
γ	——— Œstrus.	Beetle-grubs.
		Bots.

The head of the THREAD-WORM is subulate, nodose, and divided into three vesicles, in the middle of each of which is an aperture by which it receives nourishment; skin at the sides of the body finely crenate or wrinkled; tail finely tapering and terminating in a point; the female has a small punctiform aperture a little below the head, through which it receives nourishment; gregarious; viviparous; about half an inch long; sometimes wanders into the intestines, and occasionally as high as the stomach.* It was first observed by Morgagni.—(Lib. xiv., 42.)

The sexes of this variety are distinct, but the male organs have not been discovered. This form of intestinal worms was first detected by Hippocrates.—(Aphor. iii.) Goetz conceives it to be viviparous, but Bremser oviparous.—(Ueber Lebende Würmer, 4to., 1819.) It is the *oxyuris vermicularis* of the latter. The animals are of a yellowish white colour, and have a general resemblance to the ends of threads cut off, and about half an inch in length, whence the name of THREAD-WORMS, and probably of BOTS, which is often, but erroneously, applied to it, and which I suppose to be a corruption of the French *bouts*, “ends” or “extremities.” The term MAW-WORM, according to Dr. Harvey, is derived from the occasional visit which this animal makes to the maw or stomach in migrating from its proper region, which is the rectum (*On Consumptions*); but, more probably, from the peculiar effects which it often produces on the maw or stomach by sympathy, and without quitting its home, as a perpetual and gnawing pain and insupportable faintness from the intolerable itching it excites in the anus. Sometimes these worms wander in a different direction, for they have been found in the pudenda: and by Frank in the urethra

* Bremser doubted whether ascarides vermiculares had ever been found out of the large intestines. Yet Bloch, long before the date of this author's treatise, had met with them in a cyst formed in the parietes of the stomach; and Brera had seen a considerable number of them in the œsophagus of a woman who died of a slow nervous fever.—(Traité des Maladies Verminenses trad. de l'Italien avec des Notes, Paris, 1804.) The worms which have been occasionally detected in the air-passages were the ascarides lumbricoides; but Cruveilhier conceives, that their lodgment in this situation would be incompatible with life, and that their arrival there must have happened after death, or during the final moments of life. In one of these periods, he thinks they passed through the œsophagus into the pharynx, and thence into the glottis. In the example recorded by Andral, the insinuation of such a worm into the larynx of a child produced suffocation.

VOL. I.—M

and the urine.—(*De Our. Hom. Morb. Epit.*, tom. vi., lib. vi.) Very generally, however, they remain quiet and inactive, convoluted in mucus and feces, and are only known to exist by their discharge. Yet occasionally they produce so much irritation as to cause a sensible tumour, or a congeries of small tumours, around the anus. They sometimes co-exist with other kinds. Rosenstein gives the case of a child, who, in conjunction with a large number of ascarides, voided ten long worms and a piece of a tænia. The little patient died screaming under the most excruciating pain and convulsions.

The larvæ of the second variety embrace several species of the SCARABÆUS or BEETLE (*Paulini*, cent. iv., obs. 8; *Timeus*, Cas., p. 120), which have not hitherto been accurately described or enumerated; but of which the following seem to be the chief; gray larva, with yellowish legs and ferruginous head, of s. nobilis; and those of s. Schoefferi, and s. volvens, which, when out of the body, deposite their eggs in round balls of animal dung, which they roll up and bury with their hind feet. Almost all the grubs of the genus *Scarabæus* delight in and feed on dung; and hence the eggs find a convenient nidus and the grubs a ready supply of food in the rectum, when accident has conveyed the former into this organ. These grubs have six feet; are annulate, hairy, vesicular at the end of the abdomen, and furnished with a horny head.

The larvæ of the ŒSTRUS, BREEZE, or GADFLY, are called bots, and are of a round figure; pale-green; tail obtusely truncate; head tapering; mouth horny, with two lips, and two recurved black claws on each side of the mouth. Found convoluted in the mucus and feces of man, but far more frequently of other animals, and especially of the horse.

The genus *œstrus* is not numerous, containing in all not more than twelve species. Of these the greater number deposite their eggs on the skin of animals, and are there hatched. The *œstrus ovis* fixes them on the interior nostrils of the sheep; from which, when hatched, they travel into the frontal sinuses or horns, and, when full fed, are discharged through the nostrils. They excite great irritation, often compelling the sheep to shake their heads violently, and rub or hide their noses in dust or gravel, and sometimes produce inflammation in the brain.

There are only three species, however, whose larvæ seem capable of being hatched in the intestinal canal. These are *œstrus equi*, *æ. hæmorrhoidalis*, and *æ. veterinus*. The eggs of the last are found deposited on the skin of cattle in general, and those of all on the skin of the horse: the part of the horse preferred by hæmorrhoidal breeze being the lips. The eggs excite a troublesome titillation, which induces the animal to bite the part and lick it with its tongue, in consequence of which the eggs are transferred from the skin to the tongue itself, and find a ready conveyance to the rectum, which is their proper nidus.*

* Such of the ova of the *œstrus* as are conveyed into the horse's stomach by deglutition become

It is the hemorrhoidal breeze whose eggs are chiefly if not solely hatched in the human intestines, and especially those of grooins and other persons, whose duty leads them to associate much with horses, and other large domesticated quadrupeds. And it is the grubs or larvæ of this genus, when discharged from the anus, that constitute the proper *Bots* of veterinary writers, though the term is often misapplied to the *ascaris vermicularis*, as observed already, to which, indeed, they have some resemblance.

Mr. Greenhaw has described a very copious discharge of transparent globular materials from the rectum of a boy of nine years of age, which he thinks were hydatids.—(*Edinb. Med. and Surg. Journ.*, No. lxxvii., p. 574). [They were of the size, and many of them of the colour of gooseberries. The editor was once consulted by a gentleman who occasionally voided from the rectum a yellowish fluid, containing small globular bodies, resembling hydatids, attended with severe irritation about the bladder.]

SPECIES III. HELMINTHIA ERRATICA. ERRATIC WORMS.

WORMS, OR THE LARVÆ OF INSECTS, INTRODUCED BY ACCIDENT, AND WITHOUT FINDING A PROPER HABITATION IN THE STOMACH OR INTESTINES; PRODUCING SPASMODIC COLIC, WITH SEVERE GRIPINGS; AND OCCASIONALLY VOMITING, OR DEJECTION OF BLOOD.

Of this subdivision we know but little; yet the ensuing instances may afford sufficient reason for forming it. It might easily be enlarged; but the authorities for extending it further are doubtful.

α Gordius.	Hair-worm.
β Hirudo.	Erratic leech.
γ Musca.	Maggots.

The GORDIUS is the seta equina, or horse-hair-worm, of the old writers. It is found in soft stagnant waters; from four to six inches long, twisted into various knots and contortions; colour, pale-brown, with dark extremities.

This disease is most frequent among the peasants of Lapland, and was suspected by Linnæus, and has been since proved, or thought to be proved, by Dr. Montin, one of his most celebrated disciples, to be occasioned by their drinking the half-putrid water of stagnant marshes or ditches inhabited by the gordius. It is not known on the Lapland mountains. The gripings are often so violent that the patient rolls and writhes on the ground in severer agony than a woman in labour, and discharges bloody

larvæ, or grubs, which attach themselves by tenacula to the lining of the œsophagus and stomach, and seldom to the interior of the bowels. When they are completely developed, and prepared for another metamorphosis, they are spontaneously loosened, and then voided with the excrement. A horse's stomach, studded with a multitude of these larvæ, not only in its epidermic or splenic portion, where they usually fix themselves, but in its pyloric part, is what everybody must have seen.—Ed.

urine. After many hours, sometimes an entire day, the disorder terminates in a profuse pyalism, that continues for a quarter of an hour. The Laplanders call the disease *Ullen*, or *Holme*.*

The SECOND VARIETY includes several species of the LEECH, swallowed, when minute and young, along with the muddy and stagnant water they inhabit.

Apparently both the medicinal and the horse-leech (*h. sanguisuga*) have been thus found; but the exact species has not been sufficiently indicated. Sauvages, in his genus *Hæmatis*, quotes Galen, Schenck, and Wedel, but does not describe the species. Upon turning to Galen, iv., 411, D., the reader will find that he briefly adverts to the disease, and quotes from Asclepiades and Apollonius the remedies that were employed in their respective days; but he does not characterize the worm.

Of helminthia, from this cause, we have numerous examples in foreign writers and journals;† but we need not travel from our own country for instances. Of domestic examples, several are related in the comment to the volume of Nosology; and though apparently well attested, are of a truly marvellous character. The fact appears to be, that, from fixing on the internal tunic of the stomach, or intestines, these worms riot on so rich and plentiful a repast, that they grow to an enormous size, and evince such a deviation from their common shape, as in some instances to be recognised with great difficulty. It is highly probable, however, that they can only live in dyspeptic patients, or persons whose digestive powers are infirm: for there are few or no animals capable of resisting the solvent power of the gastric juice when secreted in full health and vigour.

One of the most extraordinary instances among those entitled to attention is related by Mr. Paisley in the Edinburgh Medical Essays.—(Vol. ii., art. xxvi.) In this case there were two worms, whose heads the author compares to that of the horse-leech, and which appear to have been tolerably quiescent in their growth, till the general system was disturbed by a wound on the breast received by the patient in consequence of a duel with the small-sword. The general symptoms of this species of helminthia appeared about the third day afterward, and continued with many variations for several weeks, when the patient discharged inferiorly one of these worms, measuring a foot and a half in length, and an inch and a half in diameter, dead, but full of blood, and accompanied by a large dejection of grumous blood, "to appearance some pounds;" and not many weeks afterward the other, still larger. A worm, apparently similar, is stated by Dr. Bond of Philadelphia, in 1754, to have been discharged downwards, by a female patient of his, who had been long subject to an hepatic disease, which gradually changed to violent helminthic symptoms in the

* Linn. Flor. Lap. de Angelica. Montin, Amœn. Acad. Splachnum, ii., 26.

† Eph. Nat. Cur., cent. vii., obs. 25. Rhodius, cent. ii., obs. 72. Blanchard, Collect. Med. Phys., cent. i.

stomach. These at length suddenly vanished, and within twenty-four hours the worm was dejected, dead, and in two parts, the whole making twenty inches in length. The patient died soon after; and on opening her, this worm appears to have worked its way, when small, into the liver, by the course of the common duct, to have committed great depredation here, and afterward, with considerable difficulty and dilation of the duct, to have travelled back again. Dr. Bond ventures to call it an *hepatic leech*; though he calculates its course as now stated.—(*Lond. Med. Observ. and Inq.*, i., 68.)

[In Egypt, the French soldiers, urged by severe thirst, frequently drank the muddy water of lakes and pools; an opportunity was thus given for the insinuation of leeches into their nostrils, and even into their stomach. The same annoyance likewise befell the soldiers of the same nation at Port Mahon, in 1757. In one of the latter cases, the patient, after having vomited up three pints of blood, requested of his own accord the proper remedy, namely, some vinegar; and as soon as this had been taken, the leeches were rejected. According to Larrey, the removal of these animals from the nostrils, when they cannot be laid hold of with forceps, is most effectually accomplished by means of a lotion, composed of nitre and diluted vinegar.—(*Mém. de Chirurgie Militaire*, tom. i., p. 362.) The long continuance of the leeches generally produced much indisposition, a loss of flesh, and sometimes delirium.]

THE THIRD VARIETY consists of the grubs of different species of that subdivision of the genus MUSCA, or FLY, whose sucker is possessed of a single bristle without a sheath, and short; clavate, furnished with a lateral hair. These deposit their eggs in game and other meats that have been long kept, and are approaching a putrid state, as *musca carnaria*, or flesh-fly; *m. vomitoria*, or blow-fly; *m. cibaria*, or pantry-fly; or perforate and lay their eggs in cheese, bacon, hams, or other salted and high-tasted viands, as *m. putris*, the larvæ of which are known to the housewife by the name of *hoppers*, as those of all of them are by that of *maggots*; which last has often, though in a looser sense, been applied to the grubs of insects generally.

From the deposit of the eggs of these species of the fly in so many branches of the common food of man, there is no difficulty in conceiving how they may pass into the human intestines. In a sound state of the stomach, indeed, we have little reason to believe that they could be hatched and live in that organ; but they may find a convenient nidus, and live comfortably in a debilitated stomach, and apparently through the entire range of the intestinal canal.

The cases of this affection are numerous. One of the best related is that of Dr. White. The patient, aged thirty, was emaciated, of a sallow complexion; had gripings and tenderness of the abdomen; costiveness, rigours, and cold extremities. Took columbo root, and occasionally calomel and other purgatives. In a month was better, and the appetite good. The next purgative brought away an immense number

of pupæ or chrysalid worms; some of which being preserved, were transformed into the *musca cibaria*.

We have also examples of the larvæ of other insects that have entered the stomach by some accident or another. Thus, Mr. Church, to whose entomological skill Dr. White confided the examination of the above paper, asserts, that he once knew a child discharge a larvæ of the caddy insect (*phryganica grandis*); and that the *phalæna pinguinalis* lives and is nourished in the stomach; and, after sustaining several metamorphoses, is thrown out, and proves its proper genus.—(*Mém. of Med. Soc. of London*, vol. ii.) Mr. Calderwood has published a like case (*Edin. Med. Com.*, ix., 223); Riedlin, examples of other fly-maggots (*Cent. iii.*, obs. 85); other writers, of the larvæ of the beetle, or the bee, discharged by the anus after violent gripings;* while Planchon describes a live spider thrown forth from the same opening.—(*Journ. de Méd.*, iv., p. 203.)

Weikard gives an instance of a *triton palustris* discharged by vomiting (*Vermischte Schriften*, iv., p. 127; *Kl. Schrift.*, p. 82); and many of the continental writers have examples of rejection by the same passage of the *lacerta aquatica*, unquestionably swallowed when minute and unperceived, with the water obtained from ponds and lakes.† In one instance not fewer than five of these were thrown back at a time.‡

But of all such marvels, the most extraordinary, and one of the best attested, is that narrated by Dr. Pickells; § consisting of enormous progenies of apterous, dipterous, and coleopterous insects, discharged both by the mouth and anus. The patient was a young woman, who had long been in a melancholy frame of mind from the loss of a beloved mother, and who, under a superstitious idea, that a certain portion of clay drunk daily, from the graves of pious clergymen, would preserve her from disease as well as from sin, contrived to stock her chamber with a large quantity of this material from the graves of two clergymen whom she had known, and which appears to have formed a bed for the eggs of the insects thus hatched in the stomach. "Of the larvæ of the beetle," says Dr. Pickells, "I am sure I considerably underrate when I say that, independently of above a hundred evacuated per anum, not less than seven hundred have been thrown up from the stomach at different times since the commencement of my attendance. A great proportion were destroyed from an anxiety to evade publicity; many, too, escaped immediately after having been vomited, by extricating themselves quickly from the vessel, and running into holes

§ Trans. of the Association of the Fellows and Licentiates of the King and Queen's College of Physicians in Ireland, vol. iv., art. viii., 8vo., 1824.

in the floor. Upwards of ninety were submitted to Dr. Thompson's examination, nearly all of which, including two of the specimens of *tenebrio molitor* (darkling), I saw myself, thrown up at different times. The average size was about an inch and a half in length, and four lines and a half in girth. The larvæ of the dipterous insect, though voided only about seven or eight times, according to her account, came up almost literally in myriads. They were alive and moving." [In an interesting appendix (Op. cit., vol. v., p. 171, &c., 8vo., 1828) to the preceding account, Dr. Pickells states, that under a persevering use of common turpentine, in doses gradually increased to the enormous one of six ounces, the larvæ of the beetle, which were the principal source of annoyance, had been destroyed, and that the patient now enjoys almost total immunity from her long-protracted and complicated diseases. In the course of a year and a half subsequent to his former communication, she had voided more than 1300 additional beetle larvæ, principally from the anus, making in the whole nearly 2000 seen by Dr. Pickells, besides many others which he did not see. Besides the beetle larvæ, dipterous ones continued to be voided at intervals during the same period, both from the stomach and the rectum; sometimes without medicine, but more frequently by the effect of castor-oil, strong doses of turpentine not killing them. Ascarides resembling the ascarides felis, were also discharged upwards and downwards, as well as numerous larvæ of blaps. Whence the constant supply of the latter was derived, is a very puzzling question in the history of this extraordinary case; for, if they propagate only in the imago, or perfect state, as is asserted, their generation within the body can hardly be supposed, as only two insects far advanced, one an imago, the other a pupa, were known to be discharged, and yet larvæ of every gradation continued to be voided to the last. Her food and drink were from the same source as those taken by other healthy persons; and she lived on an upper floor where the kind of beetles, which she voided, are not usually found.]

Many of the larvæ or insects thus thrown up had been preserved alive in clay or pill-boxes, for upwards of a twelvemonth, at the time of writing. Pain in the stomach, suppression of the menses, irritation of the bladder, hæmatemesis, occasional perversion of all the external senses, vertigo, convulsions, catalepsy, mania, delirium, and various other affections of the nervous system, indicative of helminthic irritation, were the sad train of evils that alternately overpowered the patient. [The quantity of blood thrown up from the stomach in the course of the case, was such as to create surprise that she should have been able to bear the loss. A retention of urine, with which she was long afflicted, was completely removed after a dose of five ounces of turpentine, a great deal of blood at first coming away with the urine. The same medicine also evinced great power in restoring the catamenia.]

To all these parasitic vermicles will apply the

remark I have already made upon a single variety; that they appear, from the luxuriance of their haunts and repasts, to be in various instances peculiarly enlarged, and altered from the structure they exhibit out of the body (*Bremser*); whence the great difficulty of determining in many cases the exact external species to which a larva, worm, or animalcula found within the animal body may belong. Yet of all the erratic worms and grubs, the horse-leech, *hirudo sanguisuga*, appears to undergo the greatest metamorphosis; and, as observed in the comment to the Nosology, is reported to have reached the size of a man's fist, and to have contained a pound and a half of blood.

GENERAL DIAGNOSIS AND TREATMENT.

We have had occasion to observe that the stomach is the great organ of sympathy, and associates in affections of the most remote parts of the system. It follows necessarily, that other parts of the system must, in various instances, associate in affections of the stomach. This is particularly the case with respect to the irritation produced by worms, and especially those that exist in the stomach itself, or the upper part of the alvine canal, as lying nearest to it.

"The evils which hence arise," says Dr. Heberden (Cap. lix., p. 243), who has well drawn up the general train of symptoms, "and which cease on their expulsion, are headaches, vertigo, torpor, disturbed dreams, sleep broken off by fright, and screaming, convulsions, feverishness, thirst, pallid hue, bad taste in the mouth, offensive breath, cough, difficult breathing, itching of the nostrils, pains in the stomach, nausea, squeamishness, voracity, leanness, tenesmus, itching at the anus towards night, at length dejection of films and mucus. The broad tape-worms produce the severest mischiefs on the body; the teretes and ascarides (round and thread-worms) sometimes lurk scarcely suspected unless there is itching of the anus, or they are traced in the feces. I have seen a broad tape-worm expelled from the intestines four cils in length. The long tape-worm (*lumbricus cucurbitinus*) seems to be a series of many worms, a single joint of which will sometimes live when separated from the rest. The round-worms have ascended into the mouth, and have even lived two or three days after they have been discharged. In two patients under my care, there was room for suspecting that the gourd-worm had induced epileptic fits, mania, and idiotism."

Upon this passage it is only necessary to observe, that the long tape-worm, *tænia solium*, or, as Dr. Heberden calls it, *lumbricus cucurbitinus*, is not a series of many worms, as this elegant writer suspected, and as, indeed, is generally suspected at present; and although its different joints, when separated from the rest, are capable of maintaining for a short time an independent life, they neither continue alive long, nor are competent to produce any increase. They have, however, been sometimes found alive at the time of expulsion.

There are mischievous effects other than Dr.

Heberden has here pointed out occasionally to be traced in remote organs, from the sympathetic action of worms lodged in the intestines. Thus the lungs, as well as the brain, have frequently been found to participate in the disease, and at times the uterus; and a profuse hemorrhage has ensued from the one or the other organ, and very frequently from the nostrils, and been repeated at uncertain intervals, in some instances without any suspicion of the real cause, and consequently with an erroneous practice. Mr. Rumsey, of Beaconsfield, has published an instructive paper upon this subject (*Transact. of the Medico-Chir. Soc.*, vol. ix.), in which various cases of sympathetic hemorrhage and pulmonary affection seem to have been relieved by an anthelmintic course.

"In all obscure diseases," says Dr. Swediaur, "attended with symptoms that are chiefly anomalous, the suspicion of the physician should be directed to intestinal worms. I once knew a case in which the patient, who was miserably afflicted with pains in various joints of the body, simulating those of arthrodynia, by taking an anthelmintic, and discharging, in consequence hereof, various fragments of a tænia with a mass of mucus, became perfectly well. So," continues he, "have I known apoplexy and palsy removed by a discharge of worms from the intestines: and had once a patient remarkable for a filthy and fungous excrescence on the nose; who lost the excrescence spontaneously after a successful course of vermifuges."*

[Intestinal worms are sometimes so numerous, that they occasion death. This is not uncommon in children from the effect of lumbrici; † and happens even to adults whose bowels contain tæniæ of extraordinary size.]

There is yet great space for improvement in the mode of treating this complaint. The larger worms unquestionably are found most frequently in young persons, or persons of weakly and inelastic fibres, and dyssthetic habits; and hence our first intention should be to invigorate the system generally, and the stomach and intestines particularly, by bitter and other tonic medicines: for it is not often that they resist a very strong living action. And yet I have sometimes found the long round-worm in persons who have made no complaint of ill health, of regular habits, and in the middle of life.‡ Worms have occasionally infested the alvine channel for years without any serious evil—the ascarides, indeed, as Dr. Heberden informs us, for thirty years, or for even the whole of a long life, without any reason to suspect that they had

hastened its end (*Trans. of the College of Phys. of London*, vol. i., p. 54); whence some writers have been fanciful enough to conceive, that, in animals of most genera, they form a mean of maintaining the general health, and are a regular part of the economy of perfect life. [Dr. Rush conceived, that they might sometimes promote health by diminishing the quantity of redundant mucus in the intestinal canal.] "Worms," says Dr. Parr, "seem to form part of a healthy constitution, and are scarcely injurious but from accidental circumstances."*

This quaint though common paradox, however, is somewhat shaken by the doctrine contained in the next paragraph; in which a very unnecessary and untenable distinction is drawn between the law which in this respect regulates animals and vegetables; and followed up by a remark at variance not only with general observation, but with the import of Dr. Parr's own reasoning upon the subject. "This circumstance," says Dr. Parr, "forms a striking distinction between animals and plants. Parasitic animals attack only debilitated plants: but the healthiest animals are chiefly affected with worms; and the observations which seem to contradict this, arise from a neglect of the distinction between the existence of worms and their *appearing* a source of disease from their *accumulation*. Their formation is assisted by accumulations of mucus; and, consequently, in children,

* Worms have even been conjectured to do good by stimulating the digestive organs, and promoting all the functions. The latter idea was that of Goeze, who, in his admiration of the universe, and especially of man, the chef-d'œuvre of the creation, endeavours to prove that all things have been created for man, because all of them are either directly or indirectly useful to him, as, for instance, even intestinal worms. But, as Cruveilhier observes, though it has often happened that numerous worms have remained in the alimentary canal without producing inconvenience, or even causing any symptom indicating their presence, it has much more frequently been the case, that complaints of greater or lesser severity have ceased directly after the expulsion of a considerable number of worms. But here, he thinks, a distinction is to be made between what is truly owing to the expulsion of the worm, and the good done by the vermifuge medicines on some other principle; for many cases are related in which epilepsy, chorea, convulsions, colic, hysteria, and a variety of other diseases, yielded to vermifuge medicines, though no worms were expelled by them. But Cruveilhier conceives that some doubt will always continue respecting what complaints truly depend on worms, inasmuch as the symptoms caused by them cannot be discriminated from such as arise from concomitant causes. He does not admit that there are any *worm diseases* (properly so called), that is to say, diseases which depend entirely on the presence of worms in the intestinal canal. He acknowledges that there are symptoms of worms, though there is nothing very characteristic in them, all being more or less vague. The certainty of the existence of worms can only be acquired by their expulsion; but, it is one thing to determine their presence, and another to ascertain what influence they have in diseases. —(*Dict. de Méd. et Chir. Pratiques*, art. Entozoaires.)—Ed.

* Nov. Nosol. Meth. Syst., vol. ii., p. 245. Cruveilhier takes a very different view of this subject from that adopted by Heberden, Swediaur, and others; for he has no faith in the doctrine which sets down intestinal worms as the cause of a multitude of obscure diseases.

† See two cases in Corvisart's *Journ. de Méd.*, tom. xii., p. 3.

‡ Dr. Elliotson has seen many individuals, who, to their great astonishment, discharged several feet of tape-worm, not having the least idea, previously, that any thing was the matter with them. —*Lectures in Med. Gazette* for 1832-33, p. 693.

sometimes in cachectic patients, they become *inconvenient*."

Inconvenient is a somewhat gentle term for expressing the fearful host of effects which we have just enumerated from Dr. Heberden, and which Dr. Parr himself has in other places arrayed in form and number quite as appalling. But if this *inconvenience* be mostly promoted by an accumulation of mucus, and if children and cachectic patients be mostly exposed to such accumulation, these worms do not seem, properly speaking, to form part of a healthy, but rather of a weakly constitution; nor can the healthiest be said to be chiefly affected by worms. And the same general law applies equally to animal and vegetable life. In both, the most imbecile are the most affected; and the strongest, when affected, are the least injured, for the very reason that they are the strongest.

The disease called *rot*, in sheep, to which I have already alluded, is a further illustration of this remark. Here the fasciola, or fluke, makes its appearance in prodigious numbers in the liver of the animal, which is sometimes entirely preyed upon and destroyed. Though there is some doubt among physiologists whether this worm be the cause or the effect of the disease, all are agreed, that the malady never appears in a wholesome atmosphere, and a strong and vigorous state of health: and it has of late been sufficiently ascertained, that tonic stimulants, and especially the stimulant property of sea-salt, whether mixed with the food mechanically or chymically, as in salt marshes, is the best and most effectual mode of cure. The food of merinos, in Spain, is therefore constantly enriched with salt; and Lord Somerville justly attributes the health of his flock, of upwards of two hundred merinos, which he purchased in Spain, to the use which he has for years made of this article on his farm. A ton of salt is the proportion employed annually for every hundred sheep.

One means, therefore, and perhaps the most powerful in our possession, of getting rid of intestinal worms, is that of strengthening the system generally, and the alvine canal particularly. Our next means is the use of what have been called anthelmintic medicines, or those which either destroy worms, or drive them from the body by qualities which torment or distress them. Both these intentions may sometimes be pursued simultaneously; and where they cannot, from the weakness of the patient, we should commence with the former. A decisive vermifuge process is yet a desideratum: for, first, worms lie for the most part so low in the intestines, or are so completely involved in viscid mucus or other slime, that oil of turpentine, tobacco-water, and mercurials, which readily enough destroy them out of the body, seldom go directly home to them when within it; and next, most of the medicines that promise to produce this effect, have a tendency at the same time to weaken the action of the stomach and intestines, and consequently to render them a fitter habitation for such unwelcome tenants.

Worms, by their irritation, augment the secretion of mucus, in which also they involve themselves. Brera says they feed upon it, and if deprived of it they die.* By keeping the bowels loose we prevent the accumulation of this slimy material in which the worms burrow: and if we have reason to believe that such accumulation has taken place, the best plan is to give active purges, as calomel, jalap, scammony, gamboge, or an intermixture of these, for its removal: and having thus, as far as we are able, exposed the naked bodies of the worms to the action of ANTHELMINTICS, we should proceed with the latter without loss of time.

The list of these is almost innumerable; and the very length of the catalogue serves to show us how little we can place a positive dependance, even at the present hour, upon any one of them as a specific.

Anthelmintics may be conveniently divided into two classes. Firstly, those that dislodge and drive away intestinal worms by some mechanical or other external action; and, secondly, those that destroy them by some narcotic or other internal means.

In the former we may rank all the drastic cathartics; all the oleaginous vermifuges, as oil of olives, beech-nuts, castor, and turpentine; sulphur, petroleum, and sea-salt; tin-filings; crude quicksilver, or Plenck's gray mucilage of it; the lunar pill of Boerhaave, formed from a preparation of silver, which may be regarded as a mild lunar caustic; and the bristly down of the pods of cowhage. In the latter we may place the male-fern, hellebore, fetid hellebore, cevadilla, tansy, savine, rue, dittany, tobacco, wormseed (*artemisia santonica*, Linn.), bark of the bulge-water-tree (*Geoffroya inermis*), and of the cabbage-tree (*arcea oleracea*); the *spigelias*, and *scabiosa Indica*.

Simple purgatives, even the most active and drastic, seem to have little other effect than that of clearing away the mucus and other viscid materials, in which most of the intestinal worms are fond of burrowing, and thus exposing their naked and tender bodies to the action of other and more direct anthelmintics. Even colocynth, which unites a bitter principle to a cathartic power, and which on this account was for ages regarded as an anthelmintic doubly armed for the field, is now well known to be incapable of poisoning them—as Redi has exposed various kinds of them to a strong decoction of this medicine for four-and-twenty hours without serious mischief.

It is, nevertheless, obvious that these medicines have their use, and are in fact of very great importance; and especially in the case of children, whose bowels are more easily loaded with mucus than those of adults, and who, on this account, bear active purgatives with much less inconvenience. In an attack upon worms, brisk cathartics should always take the lead. They ought not, however, to be too frequently repeated, nor continued through a long series;

* Lezioni sui Principali Vermi del Corpo umano, 4to., Crema, 1801.

as in this case, they will rather augment than diminish the mucus by their own irritation.

Upon the oleaginous vermifuges we can place but little dependence, if we except the terebinthines. Olive and castor-oil may be of slight subsidiary benefit, by mixing with the surrounding slime, and removing it by what purgative power they possess; but their chief benefit, if they be serviceable at all, is probably in greasing the bodies of the worms, and blocking up their stigmata or respiratory pores:* in which view, they are better adapted for the cure of worms that infest the stomach and upper intestines, where they can exert their power at once, and without dilution or chymical change, than for those that take up their habitation lower; and especially for the cure of the long round and the long thread-worms, as these are killed more readily than the tape-worms, which often only perish by single joints. For the cure of vermicular ascariides,† or maw-worms and bots, these oils have been used in the form of injections: but we have no decided proofs of any great benefit that has been derived from their use in either way, in respect to the worms, for which, indeed, they are rarely to be recommended, though they are often useful in taking off the irritation of the mucous membrane itself.

The terebinthinate oils are far better entitled to our attention, and appear to act as purgatives upon the bowels, and as external irritants upon

* This remark does not agree with the conclusion at which Cruveilhier arrives, who reminds us that fixed oils were proved, by the experiments of Arneemann and Redi, to have no specific power against worms, and that castor-oil is efficacious only as a purgative. Human ascariides, immersed in it, lived not less than from forty-four to forty-eight hours. Cold, alcohol, and empyreumatic oils destroy worms instantly. In several instances where worms occupied the great intestines, Cruveilhier found cold clysters successful.—(Dict. de Méd. et de Chir. Pratiques, t. vii., p. 352.)

† Of all the kinds of intestinal worms, the ascariides vermiculares, or oxyures, are the most easy to detect, for their favourite residence is in the folds or the lower part of the rectum, where they produce violent itching, and sometimes excessive pain. When there is reason to suspect them, the lower end of the bowels should always be examined. In several cases mentioned by Cruveilhier, complete relief was afforded by keeping mercurial ointment applied to the anus for a few days. This author has remarked, that ascariides vermiculares very commonly cause inconvenience chiefly in the night-time, after the young patients have been put to bed. He considers it probable, that they only cause uneasiness when situated near the lower end of the rectum; and in this manner he endeavours to account for cases on record, where patients had no ailments, though they passed a vast number of vermicular ascariides.—(Dict. de Méd. et de Chir. Pratiques, art. Entozoaires.) Sometimes these animals get into the vagina, and occasion intolerable itching, and even, as is alleged, nymphomania. In one instance, related by Beck, the injection of a bitter decoction into the vagina brought away a large number of oxyures, and gave prompt relief. A solution of the sulphate of iron is also known to destroy ascariides very promptly.

the worms exposed to them. The vermicular ascariis rarely resists their use when given in a dose sufficiently large to reach the rectum, or when injected into this organ; and has been discharged in great abundance.* The alvine worms, if not equally affected, are nearly so; even the tæniae have yielded to their acrimony.† The rectified oil of turpentine is that in common employment. [Convincing proofs of its efficacy in cases of tænia were published by Dr. Fenwick (*Med. Chir. Trans.*, vol. ii.), of Durham, to whom the merit of its first administration has been erroneously referred, not only by the author of this work, but other distinguished men.‡ Turpentine was recommended for its anthelmintic virtues even by Bartholine (*Epist.* iv., p. 345), and Chabert's celebrated remedy consisted principally of it.—(*Journ. Encyclop.* 1781.)] Turpentine is usually given in doses of from half a drachm to a tea-spoonful to an infant, and from an ounce to an ounce and a half to adults, alone, or with a little peppermint or cinnamon-water; though for infants the best medium is milk. These doses, however, may be considerably increased, and will in many obstinate cases be found insufficient. [In the extraordinary case already quoted, Dr. Pickells gradually increased the dose of common turpentine to six ounces.—(*See Trans. of Assoc. Physicians*, &c. Ireland, vol. v.)] A child of ten or eleven years old may take an ounce without any evil effect in ordinary cases: but, in delicate habits, a full dose sits uneasy on the stomach, and disquiets the system generally, though in different ways; for it sometimes produces a general chill and paleness, sometimes a tendency to sleep, and sometimes an alarming intoxication. It is in small doses alone, as half a drachm or a drachm to an adult, that it enters into the circulation, and proves an acrid irritant to the bladder, often exciting bloody urine.§

* For destroying worms, "one of the best remedies is unquestionably oil of turpentine. In the case of ascariides, which are easily known from their crawling out, from their appearing in the stools, and from the extreme itching which they cause in the rectum, it is best to give the oil of turpentine by injection. You thus send it immediately on the part where the worms reside; you save the patient the trouble of a filthy dose, and you save the stomach from great disturbance. From a drachm to half an ounce may be given to a child, mixed with gruel, and it will often bring away thousands. Adults will take an ounce or more in an injection," &c.—Elliotson's *Lect. in Med. Gazette*, 1832-33, p. 692.

† Diseases of Tropical Countries. By C. Chisholm, M. D., p. 99, Lond., 8vo., 1822.

‡ See Gregory's *Elem. of Physic*, p. 521, 2d edit. In 1792, Mr. Madden, a surgeon at Putney, seems to have mentioned oil of turpentine as a good medicine for worms (*Trans. of Lond. Med. Soc.*), but he was anticipated by others, as explained in the text.—Ed.

§ Dr. Elliotson recommends it not to be given to the patient when he is fasting, lest it create sickness. When it does not operate well downwards, he gives castor-oil, and repeats it every two hours, till the turpentine has found its way

The subject requires further attention than it has hitherto received ; for it is probable that some of the terebinthinate essential oils, while equally deleterious to worms, are less disposed to disagree with the stomach and affect the system, as the Hungarian balsam, or distilled oil of that variety of the *pinus silvestris* which has been called *mugnos* ; or the distilled oil of the green cones of the same tree, formerly called *oleum templimum* ; and at one time sold at a high price, as a great secret, by German itinerants, under the name of *KRUMMHOLZÖHL*.

[In 1823, Dr. Kennedy proposed the exhibition of the oil of croton for completing the expulsion of intestinal worms, after their destruction by oil of turpentine, or other anthelmintic medicines.—(*Lond. Med. Repos.*, Feb., 1823.) In Italy, the oil of croton has been tried by Puccinotte (*Annali Universali di Medicina*, Aprile e Maggio, 1825) as a means of destroying tæniæ, as well as procuring their prompt discharge. One drop of the medicine was exhibited in beef-tea, at intervals of two or three days ; the first dose expelled many fragments of the worm ; and a little perseverance in the plan soon effected a perfect cure.]

The petroleum, pisseleum, and animal oil from horns, all of them highly esteemed as vermifuges in former times, possess like virtues, but in a subordinate degree, and are more unmanageable in preparing them for the stomach. Chabert, Goetze, and Professor Bremser,* of Vienna, who has cultivated this subject more attentively, perhaps, than any other pathologist in Europe, unites some one of these empyreumatic oils with the oil of turpentine, giving a third part of the former with two thirds of the latter : one or two tea-spoonfuls of this mixture being the ordinary dose at night and noon.

[According to Dr. Larini (*Mem. of the Acad. of Turin*, vol. xxv.), the plant called samphire (*Critthum maritimum*) is a powerful vermifuge, especially in cases of lumbrici ; a virtue that seems to depend upon its containing an oil very similar to petroleum.]

The sulphureous and Harrowgate waters, and those of Barèges, appear to act in like manner ; they are double irritants, and probably goad the worms while they stimulate the bowels. [Whether pure sulphur, uncombined with oxygen or the alkalis, has a vermifuge power, is doubted.—(See *Dict. des Sciences Méd.*, l. 57, p. 201).] But the efficacy of all these is far less than that of the essential oil of turpentine.

Concentrated sea-water, or a briny solution of sea-salt in spring-water, has been recommended from very high authorities, and has been found in many instances highly advantageous. It acts upon the same double principle as the preceding, though probably with more energy. The acrimony of sea-salt is troublesome to every variety of intestinal worms. I have already

observed, that it is the best prophylactic against the attack of flukes in sheep, while it gives, at the same time, a healthy stimulus to the visceral organs ; and where leeches, or indeed any of the erratic division of worms or larvæ are suspected, we are nearly certain of its proving a ready cure from its effects on the same animals out of the body. In the case of maw-worms, it is better to throw up the brine in the form of an injection ; but where these are found to be migrating up to the stomach, it should be taken by the mouth. There is a striking example of the benefit of this treatment published by Mr. Leigh Thomas, of Hawarden, Flintshire. The patient is stated to have been reduced to a very high degree of danger, and to have suffered from the disease almost without intermission for five years, perpetually wishing for death to put an end to his tortures. He was cured by the accidental recommendation of this remedy of salt and water, which was stated to have wrought wonders in a similar case. He accordingly swallowed two pounds the next morning, dissolved in two quarts of spring-water : he was vomited and purged violently, but discharged by both apertures a prodigious quantity of ascarides involved in mucus. He suffered at the same time much from the common effects of so large a portion of sea-salt, and particularly from strangury ; but finding that he had now obtained an engine with which to move the invading host, he repeated the same dose a few days afterward, and with the same effects, both good and bad. In a few days, however, he lost every painful symptom, and gradually recovered perfect health.—(*Med. Trans. of the College*, vol. i., art. iv., p. 54.)

On what the anthelmintic virtue of tin-filings depends is somewhat doubtful : nor can they be regarded as an efficient medicine. Yet Dr. Alston was much attached to them, and especially as a cure for the tæniæ, and gave them in doses of from two drachms to an ounce in treacle. He ascribed their benefit to a slight combination with arsenic ; but it is now fully ascertained, that the metal is at least as successful in its purest state ; and its effects are generally supposed to be altogether mechanical. This is certainly the case with crude quicksilver, though not with the gray mucilage of mercury, or the lunar pill, which probably stimulate the tender skin of intestinal worms, and especially those that are fond of burrowing in the mildest mucus, to some spastic and painful retraction. The last was a favourite vermifuge with Boerhaave ; and Baldinger was as fond of the first, and asserts that it is peculiarly efficacious in expelling the long thread-worm.

Perhaps the most powerful and successful of the irritants that act by an external power, is the prickly and pungent down of the pods of the cowhage (*dolichos pruriens*, Linn.), which has long been held in deserved estimation. This plant is a native of India. One of the first accounts, if not the earliest, published of it in this country, is that of Mr. Kerr, at that time a resident at Patna. It was addressed to the Professors of Medicine at Edinburgh, and was

out. In this manner, he prevents the dangerous consequences which turpentine has sometimes produced.—*Lect. Med. Gazette*, 1832-33, p. 694.—Ed.

* Ueber lebende Würmer in lebenden Menschen, 4to., Wien, 1819.

given to the world in the Medical Commentaries.—(*Med. Trans. of the College*, vol. ii., p. 82, 202.) Its powers as an anthelmintic were at the same time detailed by Mr. Cochrane, whose character of it was soon afterward fully confirmed by Dr. Bancroft, from long personal observation in South America.—(*Essay on the Natural History of Guiana*, London, 1770.) After stating the frequency of worms of all kinds in that quarter, and endeavouring to account for it, he adds, that from whatever cause these worms originate, their number is so great, and their power so prolific, that the usual remedies are insufficient for their destruction; for which reason the planters in general have been induced to employ cowhage. "Who first suggested it," says Dr. Bancroft, "I know not, but its efficacy is indisputable. The part used is the setaceous, hairy substance, growing at the outside of the pod, which is scraped off, and mixed with common syrup, or molasses, into an electuary: the dose, a tea-spoonful to a child, and double to an adult, in the morning, fasting, and repeated the two succeeding mornings, after which a dose of rhubarb is usually subjoined." The planters in this manner commonly give it once in three or four months to their slaves in general, and especially to the children of their slaves; and the author tells us, that he has known it thus administered to hundreds, from one year old and upwards. The patients, after the second dose, usually discharge an incredible number of worms, mostly the long round and the long thread-worm, amounting to more than twenty at a time, the stools consisting of hardly any thing else. And irritating as these spiculæ are to our own skin, when involved in the viscid materials with which they are mixed up, they do not seem to form an inconvenient medicine; and Dr. Bancroft never saw any evil produced by it. Of its effects upon the vermicular ascaris, he says he cannot speak, as he has not seen it tried for this variety of invagination. For this last purpose the best mode of employing it is in the form of mucilaginous injections. It was a favourite medicine with Dr. Macbride, who has warmly recommended it.—(*Introduction to the Theory and Practice of Medicine*.)

Of the vermifuges that seem chiefly to operate on worms by attacking them internally, and to expel them by destroying their life, it may be observed, that almost all of these possess great pungency and bitterness; but that those which have obtained this character, and are bitter alone, are but little entitled to it, and are only of use when combined with some acrimonious irritant. We have already remarked, that even the intense bitter of the colocynth does not destroy worms: and Dr. Cullen judged the same respecting the seeds of the *artemisia santonica*, from their repeated anthelmintic power, vernacularly called WORM-SEED, so warmly espoused by Baglivi, and supposed, at one time, to be a specific against the long-worm. "It is said," observes Dr. Cullen, "to be the lumbrici teretes (the long round-worm, *ascaris lumbricoides* of the present system), to which they are especially adapted;" but, from Redi's experiments, it ap-

pears that bitters are not an immediate poison to these animals; and Professor Murray properly observes, "that if the semen santonicum (worm-seed) according to Baglivi's experiments, operates more quickly, it must be by something else than its bitterness that this seed operates. I am uncertain if I have ever been possessed of the best kind of this seed, but must say, that what I have seen has hardly ever appeared to me to be a powerful medicine."—(*Mat. Mcd.*, part i., chap. ii., p. 62.) So far as my own observations extend, I can confirm this opinion. But the seeds are so often adulterated with those of other plants, and especially those of southernwood, that it is difficult to speak with precision.

The same remark may be made in respect to tansy, savine, rue, bastard dittany, or fraxinella (*dictamnus albus*, Linn.), and not the dittany of Crete, which is an origanum, the seeds of the *chenopodium anthelminticum*, or worm goose-foot, angelica, and many other leaves and seeds of slighter efficacy, which have had their day, and are forgotten, some of them undeservedly so. They have all more or less a bitter principle, in combination with some acrid quality, which exacerbates the energy of the bitter, and renders it doubly obnoxious to these internal parasites. And it is to these principles we are to ascribe the efficacy of the pomegranate-root, one of the most common, and, according to Dr. Ainslie, one of the best established vermifuges in India.* Linneus asserts the angelica (*angelica archangelica*) to be peculiarly serviceable in expelling the gordius, or hair-worm; and that it is in common use for this purpose in Lapland, where this variety of vermination is indigenous.

On what ground asafetida is to be held as an anthelmintic, I do not exactly know. Hoffman regarded it as one of the most powerful medicines in the vermifuge class; and Dr. Cullen tells us, that he has no doubt of its being entitled to a place in the class, though he confesses that he has seldom found it effectual; which

* According to M. Deslandz, it is used by the negroes of St. Domingo for the same purpose. The bark of the root may be administered in powder, the doses being from eight grains to a scruple, twice or thrice a day. The decoction employed in India against the tape-worm, is made by boiling ʒij. of the bark in a pint and a half of water, down to ʒix., of which ʒij. are given as a dose every half hour, until the worm is expelled, which generally occurs in twelve hours.—(See Thomson's *Elem. of Mat. Med.*, vol. ii., p. 33.)

A decoction of the rind of the pomegranate is considered to be a poison to the tænia. A broad tape-worm was put by Gómez into a decoction of it, when it instantly became stiff and motionless.—(See *Dict. de Méd. et de Chir.*, t. vii., p. 352, art. ENTOZOAIRE, par Cruveilhier.) Mr. Breton placed live tæniæ in a decoction of pomegranate bark, and also in a mixture of the powder with water, and he found that when the tæniæ were plunged in these preparations, they died in five minutes.—(*Med. Chir. Trans.*, vol. ii.) That their death arose from the influence of the bark is evident, as these worms live several hours after expulsion, when kept in simple tepid water.—(See Thomson's *Elem.*, loco cit.)—ED.

however he imputes to our not having it in so recent and diffusible a state as were to be wished. It is very probable, indeed, that it loses much of its virtue with the loss of its freshness; for Kæmpfer informs us, from his own observation, that a single drachm of the recent juice smells stronger than a hundred pounds of such as is commonly sold in Europe. Like the preceding medicines, therefore, it is not improbable that whatever anthelmintic virtue asafetida possesses when fresh, depends upon a bitter principle combined with a pungent and volatile aroma.

The hellebores, helleboraster, and cevadilla, which is usually regarded as a species of veratrum, or white hellebore, though the specific characters have not been very clearly ascertained, are pungent bitters united with a strong cathartic power, and are hence very active vermifuges; but they are too violent for common use, for they often do more mischief than the disease for which they are a remedy. The seeds of the cevadilla are so pungent as to be caustic in their pure state, for they are usually contaminated with parsley and hellebore-seeds; and are hence often employed in decoction, or some other form externally, to destroy bugs, lice, and other vermin. The dose, for a child from two to four years old, is two grains; at eight, five grains; from eight to twelve, ten. These are all powerful errhines. Tobacco is possessed of all these qualities, and unites with them a deadly narcotic power. It is hence, therefore, a decisive vermifuge; but, from its violence, can rarely be used except in injections, in which form it succeeds admirably against the small ascarides.

Gamboge seems chiefly to act as a drastic purgative, bearing down all before it; for though, when held some time in the mouth, it discovers considerable acrimony, it has few pretensions to bitterness. Yet, as it is said to be peculiarly efficacious in detaching and expelling the tape-worm rather than the other kinds, it probably acts also by some specific power with which we are not acquainted.

Some medicines, however, may be regarded as specific vermifuges; or, in other words, as acting upon worms, and detaching or destroying by some simple quality which proves highly offensive or poisonous to them, without affecting the bowels; and which, therefore, prepare them for rejection by any purge that may be given afterward; the chief of which seem to be the bark of the shoots of the cabbage-tree (*arcea oleracea*, Linn.), the bark of the bastard cabbage-tree (*Geoffroya inermis*, Linn.), and the male fern.

The two former are West Indian and American plants, and the barks are employed in the form of infusion, decoction, syrup, and even powder. Both have a mucilaginous and sweetish taste, and the first a disagreeable smell. Their destructive power depends upon no sensible quality; for though, when given in large doses, they will vomit and purge violently, they prove far less anthelmintic in this proportion than when administered in doses that lie easy

on the stomach and bowels, and do not pass away with rapidity. By such retardation the worms are exposed to their full influence, and are either killed or rendered sickly,—so that it is necessary to take a dose of jalap, or calomel, or both, for their removal. The vermifuge is given in the morning, for eight or nine days in succession, and the purgative on the day ensuing. From the offensive smell of the *geoffroya*, it has also been called bilge-water-tree. It was first brought into notice in our own country, as a common and almost infallible vermifuge in Jamaica, by Mr. Duguid (*Essays, Physical and Literary*, vol. ii.), and afterward more fully described and recommended by Dr. Wright.—(*Phil. Trans.*, vol. lxxvii.) The decoction is made by boiling an ounce of the fresh-dried bark in a quart of water till it acquires the colour of Madeira wine; the syrup is prepared by adding sugar to the decoction. The former has found a place in the extant Edinburgh Pharmacopœia.

The *arcea oleracea* has been long known to the world as a valuable plant for other purposes than the present. Its medulla, or pith, forms an excellent sago; and its green tops are cut and eaten as cabbages; whence, indeed, its vernacular name of cabbage-tree. For a knowledge of its virtues as an anthelmintic, we are, however, chiefly indebted to Dr. Rush, who principally tried it in the form of syrup, which is of a pleasant taste, and which he asserts to be an infallible antidote. It is used, he tells us, very generally by physicians in the West Indies; and he himself has employed above thirty pounds of it, without knowing it to fail in a single instance. It is especially available against the long-worms. It was, antecedently to this, tried at Edinburgh, in the form of powder, but relinquished, as too rough and violent a medicine. In that of a syrup it is sufficiently mild, and neither purges nor vomits, but in an overdose.—(*Edin. Med. Comm.*, vol. i., p. 329.) Dr. Monro has since introduced it into St. George's Hospital, and in various cases found it successful.—(*Edin. Med. Comm.*, vol. ii., p. 97.)

The *filix mas*, or male fern, is not the only species of the ferns whose roots have been employed as simple vermifuges; for the *osmundia regalis* has acquired, with some practitioners, as high a reputation; but the favour of the public has been so much more extensively bestowed on the former as to enable it altogether to eclipse the pretensions of its rival. It is very difficult to say on what the destructive power of the male fern over worms, and especially the tænia, depends; for, to the taste, it discovers but little activity, and has little or no aroma. It is glutinous, sweetish, very slightly bitter, and substringent; may be taken in very large quantities, and appears to be incapable of expelling worms, how much soever it may destroy them, without the aid of active cathartics. And hence many writers of authority, and among the rest Dr. Cullen, are doubtful of its possessing any anthelmintic power whatever.—(*Mat. Med.*, part ii., chap. i., p. 41.) The German writers, how-

ever, give examples of tæniae discharged whole, or in long portions, and perfectly dead, after an exhibition of repeated doses of this medicine, where no cathartic whatever was made use of; and Dr. Parr asserts that he has met with like examples in his own practice. And hence it appears to exercise some poisonous effect on worms, though harmless to the human stomach.

About the year 1770, the male fern was brought into great notice in Switzerland and France, by the celebrated Madame Nouffleur, who, under her own process of using it, boasted of it as a specific, but kept the process to herself. The secret was at length purchased by the King of France, and liberally communicated to the world. The patient, according to M. Baumé's statement,* after being prepared at night by an emollient clyster, and a supper of panada, is, early the next morning, to take three drachms of the fern at a dose, and to repeat it instantly, if the stomach should reject it. Two hours after which he is further to take a bolus, consisting of twelve grains of calomel, twelve grains of resin of scammony, and five grains of gamboge, which, it must be confessed, seems admirably calculated for a triumphant issue in some way or other; for it will probably either kill the worm or kill the patient. It is by no means necessary to give so violent a cathartic.†

It is far less difficult to account for the real or supposed specific virtues of the Indian pinks, or worm-grasses, for there are two species of the spigelia that have been employed for this purpose,—*s. anthelmia*, and *s. marylandica*; and for those of the Indian scabious shrub, called by the natives cattu schiragaam. These are all acrid narcotics; in large doses, as above, two drachms, or two drachms and a half, sometimes purging violently, sometimes producing vertigo, dimness of sight, drowsiness, and clonic convulsions; and sometimes producing all together; and hence, the same violent effects being excited, perhaps, in the parasitic worms as in the patient, it is not to be wondered at that they should fall a sacrifice to them, or endeavour to save themselves by a timely and rapid escape. The scabious shrub, however, seems to act more feebly than the Indian pinks, and is little to be depended upon; while the latter are far too acrimonious for general use.

Before closing the subject, I will just observe that Dr. Friske, of Brunswick, has lately employed electricity as an anthelmintic, or rather with a view of killing the worms in their mucous domiciles, by passing powerful shocks through the abdomen. He thinks he has by this plan destroyed even the tæniae; yet he does not choose to rely upon this practice without the use of active cathartics.

* *Elémens de Pharmacie.—Précis de Traitement, &c., publié par ordre du Roi. Paris, 1775.*

† The method of Bourdier, formerly physician to the Hôtel Dieu at Paris, consisted in giving the patient, before breakfast, ʒj. of sulphuric ether in a glassful of the decoction of the root of the male fern. A few minutes afterward, a clyster, similarly composed, was administered; and, in an hour, ʒij. of oleum ricini. This plan was continued for three days.—Ed.

There is also a much milder remedy, that has been adopted in Germany, upon the efficacy of which I cannot speak from personal knowledge, but which is well worthy of attention; and especially in respect to patients of irritable stomachs and emaciated constitutions; and that is, the use of mare's milk, particularly in cases of tænia.

[Notwithstanding the kind of argument brought forward by Cruveilhier against the reality of worm-diseases, the most experienced practitioners agree that worms frequently derange the constitution, and that if you can free the patient from them, his health will return. But there is reason to believe that, in many instances, worms are induced by bad health. Hence, as Dr. Elliotson explains in his valuable lectures, there are often two indications in the treatment: one is, to expel the worms; the other is, to endeavour, by every possible means, to restore the health; "to take care that the patient has wholesome food, and to put the digestive organs into the best order you can. If this be done, you will frequently find worms disappear, without any other means being employed. Without giving any purgative medicine whatever—without doing any thing to expel or destroy worms, you will find, in a great number of cases, where children have become their prey, they will spontaneously cease. Children are far more subject to ascarides* and lumbrici than adults, and a great number of children have them at a particular time; but as puberty arrives, the constitution is less favourable as a habitation for worms, and they cease spontaneously."]

GENUS XII.

PROCTICA.

PAIN OR DERANGEMENT ABOUT THE ANUS, WITHOUT PRIMARY INFLAMMATION.

THE name of this genus has been taken from Linnæus: Segar and Macbride have formed a like genus, under that of Proctalgia. In the scope in which it is here employed, the author included six species; all of them occasionally met with as idiopathic diseases, though several of them, perhaps, more generally as symptoms or sequels of other affections. [The species proctica simplex, or simple pain at the anus, has now been omitted by the editor as an unnecessary distinction, throwing no light either on pathology or practice. The species are therefore reduced to five:—]

1. Proctica Spasmodica. Spasmodic Stricture of the Rectum.
2. ——— Callosa. Callous Stricture of the Rectum.
3. ——— Tenesmus. Tenesmus.
4. ——— Marisca. Piles.
5. ——— Exania. Falling down of the Fundament.

* Enemata of lime-water, or of lime-water and milk, as recommended by Dr. Eberle (*Practice of Medicine*, vol. ii., p. 350), will be found valuable for removing ascarides.—D.

SPECIES I.

PROCTICA SPASMODICA.

SPASMODIC STRICTURE OF THE RECTUM.

PAIN IN THE RECTUM REMITTENT, SOMETIMES INTERMITTENT; INCREASED DURING EXPULSION OF THE FECES; VOLUME OF THE FECES SLENDER BUT VARIABLE; RIGID GRASP OF THE SPHINCTER ON INTRODUCING THE FINGER; STRUCTURE OF THE BOWEL SOUND.

STRICTURES of the rectum are produced by a spasmodic contraction of its sphincter muscles, or by a thickening and induration of its coats. The first forms the species before us: it is the simplest and least formidable of the two affections, though generally very obstinate; it also occurs by far the least frequently, and has hence attracted but little of the attention of medical writers. The second, which often terminates in a scirrhus disease, will be found to constitute the next species.

The glandular structure of the rectum renders it peculiarly irritable, and the natural arrangement of the fibres of its sphincters gives it an habitual tendency to contract. It is hence easy to conceive, that any undue stimulus may excite an inordinate degree of contraction in the sphincters, which may be propagated to a greater or less degree of ascent through the muscular tunic of the bowel. This inordinate action will, at first, be disposed to cease on a cessation of the stimulating cause; but if the stimulating cause be frequently repeated, or of long duration, the contraction may become permanent, and continue to exist after the cause has been removed.

A like predisposition to inordinate and permanent contraction may take place, as Mr. Copeland has ingeniously remarked (*Obs. on the Principal Diseases of the Rectum and Anus*, sect. iv.), from the peculiar structure or peculiar extent of the sphincter fibres in particular individuals. Anatomists have not come to a unanimous agreement, whether these fibres, issuing from the exterior and the interior surfaces of the extremity of the rectum, and freely decussating and intermixing in its substance, be two distinct muscles, or only a single one. The older anatomists seem to have been of the latter opinion; Dr. Baillie, M. Petit, and M. Portal speak of them, and describe them as distinct sphincters. Be the fact as it may, we sometimes find that the two layers of fibres do not act correspondently, and that the contractile power of the one follows, instead of keeping pace with, that of the other, or evinces some other mode of inaccordancy, so that the entire muscle is seldom left in a state of perfect rest and relaxation. And we also find, that, in some individuals, even where the action is harmonious, the contractile organ is too broad or too powerful to be overcome by the expulsive power of the abdominal muscles; and consequently, that the feces are expelled less frequently and less freely than they ought to be; whence a habit of costiveness is induced, and the confined excrement, becoming

acrimonious by its lodgment, forms a permanent source of irritability, and is constantly augmenting the contractile propensity.

Any other local irritation, under such an irregularity of muscular structure, must have a like effect: as a daily use of acrid purgatives, in small quantities, with a view of counteracting costiveness; irritable caruncles, or excrescences at the verge of the anus; a tumescent and especially a varicose state of the internal hemorrhoidal vessels. And even where there is no such irregular construction of the sphincters as we are now contemplating, any of these accidental sources of stimulus, in a debilitated and irritable habit, or a debilitated and irritable state of the alimentary canal, in which all of them are most prone to occur, may lay a foundation for the same complaint.

Mr. Copeland has favoured the world with some valuable remarks upon this disease (*Obs. on the Principal Diseases, &c.*, sect. iv.); but the only writer who has hitherto distinctly described it, by what may be called a close and full length portrait, is Dr. Baillie (*Med. Trans.*, vol. v., art. ix.); and I shall avail myself of his words, as containing a correct expression of the complaint.

After noticing that strictures of the rectum are almost constantly produced by a thickening of its coats, in the progress of which ulceration very commonly takes place on the inner surface of the bowel, and the patient is ultimately destroyed, as the ulcer has no tendency of itself to heal, and the art of medicine has hitherto failed in communicating to it any healing disposition, this distinguished pathologist proceeds as follows:—

“Another kind of stricture, however, occasionally occurs in the rectum, much less formidable in its nature, which is very rare, and has hitherto been taken little notice of by practitioners. This is not attended with any diseased structure of the coats of the rectum, but depends upon a contraction, more or less permanent, of the sphincters of the anus.

“A good many years ago, a very well marked case of this kind fell under my notice, an account of which it may not be improper to communicate to the college.

“The patient in whom this disease occurred, had been long subject to an herpetic eruption on his right leg. This suddenly disappeared, and a certain quantity of blood was then daily evacuated by the bowels at the time of passing a stool, for five or six months. When the discharge ceased, there came on a good deal of difficulty in having a motion, which was immediately followed by a considerable sensation of pain in the very lowest part of the rectum. This pain generally continued from a quarter to half an hour, and then subsided entirely until the next time of having a motion. When the stools were examined, they were found to be very small in their diameter, to be flattened upon their surface, and to be serpentine or twisted. In the course of the disease, when there was an effort to have a motion, the external sphincter of the anus would sometimes hardly open

itself, so that fluid feces only would escape at such times, and in small quantity; or if any solid feces were allowed to pass, they were so squeezed by the very narrow aperture of the sphincter as to become nearly as thin as a riband. At other times, the sphincter was much more disposed to open itself, and the stools were then of a considerably larger size, and of a less flattened shape. At no time, however, were the motions of the usual size, or of a perfectly cylindrical form. An examination of the rectum was occasionally made per anum, and the rectum was always found to be so much contracted as to admit with difficulty the forefinger. This contraction extended to the upper limit of the internal sphincter of the anus, above which the cavity of the bowel was of its usual size. The internal membrane of the rectum in the contracted part was perfectly healthy. It was soft, not thicker than usual, and moved very readily on the inner surface of the contracted sphincter. The patient was in good general health, looked well in his countenance, was not the least emaciated, and his pulse was of the natural frequency.

"The patient was very averse to the introduction of a bougie, and this instrument was never passed into the rectum. Nothing therefore was done, except keeping the bowels free from costiveness, and pursuing a very temperate mode of living. The disease gradually became very much less, and although it has not altogether subsided, yet hardly any inconvenience is felt from the remaining degree of contraction. It is now nearly seventeen years since the commencement of the disease.

"This case is very different in its nature from the usual stricture of the rectum, and it is of considerable importance that it should be distinguished from it in practice. In the one case, the prognosis would be favourable; and in the other case, it would be generally very much the contrary. Upon a slight degree of attention, the two cases might be confounded; but when accurately examined, they may at all times be clearly distinguished from each other. In both cases, the feces will be found to be flattened in their shape, small in their size, and in some degree serpentine or twisted; but the other symptoms will be found to be very different. In the common stricture of the rectum, the situation of the stricture is generally two or three inches above the outer sphincter, and there is a sound capacious portion of the bowel between the stricture and this sphincter. At the seat of the stricture the coats of the rectum are felt to be more or less thickened, and, not uncommonly in the cavity of the stricture, there is a hard irregular ulcer. Although this disease has in its early stages little influence upon the constitution, yet when it has made a further progress, the powers of the constitution become very much weakened, great emaciation generally takes place, and the patient is destroyed. In the other species of stricture produced by a contraction of the sphincters of the anus, the contraction is found upon examination to be at the anus, or very

lowest extremity of the rectum, the inner membrane of the rectum is discovered to be sound (See *Fr. Salmon on Stricture of the Rectum*, p. 19, Lond., 1828, 8vo.), and the general health is not impaired."

In a particularly obstinate case of spasmodic stricture of the rectum, that fell under the care of our author, bougies of all sizes and descriptions were tried; and some tubercles, which were situated at the verge of the anus, were repeatedly cut away; but without success. He adds: I cannot, however, but regard this as an extreme case; and, in those of less violence, should still recommend the daily use of bougies of as large a size as can at first be borne without much inconvenience, gradually increasing them in diameter: for where the resistance is capable of being overcome, this is the most effectual method. In the meantime, vapour baths, or the warm bath of a bidet, may occasionally be used with advantage; and where there are exacerbations of pain, they may often be taken off by small opiate injections, not exceeding an ounce or an ounce and a half in quantity.

In the case above referred to, little benefit was ever derived from local applications of any kind, whether in the form of vapour, warm water, or cataplasms. It was most unfortunate that opium could not be had recourse to; for in every proportion, whether large or small, it threw out a lichenous rash over the surface of the body, but more especially over the extremities, possessing a heat, itching, and pricking more intolerable than the prickly heat of the West Indies, and which was almost sufficient to excite madness. From the dilatation produced in the orbicular fibres of the iris by a drop or two of infusion of belladonna, I recommended that the bougies, when they were employed, should be smeared with a preparation of the same plant; but no sensible benefit was hence obtained. The belladonna was afterward employed in the form of pills, each containing a grain of the extract. One of these, introduced into the rectum by a small ivory tube with a piston, that thrust it out when it had ascended about an inch high, was at first employed every night alone; in a few days, night and morning; and then one in the morning and two at night. No effect of any kind was experienced till the dose was thus enlarged; and here all the mischievous results of belladonna were produced, and nothing else. The tongue swelled, and lost its power; the head was confused and giddy; the mind wandered; and the sight and hearing were obtunded. Having been warned of such possible effects, and the means of removing them if they should occur, the friends of the patient had immediate recourse to the plan laid down; and, by the aid of copious stimulating and cathartic injections, and cordial draughts, a recovery was accomplished in about twelve hours.

It is obvious, however, that this case was governed by an idiosyncrasy not often to be met with: and hence, notwithstanding the failure both of opium and belladonna in a single in-

stance, I should feel it my duty to try either or both, with unhesitating freedom, in other examples, and should do it with a strong confidence of benefit. Mr. Copeland informs me, that he has often been successful with the latter; and, in some instances, where every other attempt at relief had failed.

I will just notice farther, that, in the above case, after a trial of almost all the aperients in the *Materia Medica*, the most convenient has been found about eight or ten grains of the black sulphuret of mercury, with about two drachms of sublimed sulphur in addition.

I have the satisfaction of adding, that, since the above particulars were written, the disease, though not entirely subdued, has been considerably diminished, and comparatively produces but little inconvenience.

Other cases that have occurred to me of the same complaint, have been less painful and far more easily overcome. In a young lady of eighteen, whom I now see only occasionally, and who could never be persuaded to use a bougie, it has given way, after nearly two years' standing, principally by the use of the hip-bath, for half an hour every morning, before she made an effort to evacuate the bowels.

SPECIES II.

PROCTICA CALLOSA.

CALLOUS STRICTURE OF THE RECTUM.

DIFFICULT AND PAINFUL EXPULSION OF THE FECES; FECES LAX, OR OF INVARIABLE SLENDERNESS; PERMANENT CONSTRICTION FELT BY THE FOREFINGER ABOVE THE SPHINCTER; STRUCTURE OF THE BOWEL THICKENED AND INDURATED IN THE CONSTRICTED PART.

A CAREFUL attention to the pathognomonic characters laid down in the above definition, will easily distinguish this species from the preceding, which, though more troublesome in its commencement, is far less formidable in its issue; since the latter, if not timely attended to, is frequently found to terminate in an ulcerated scirrhus, and sometimes a cancer.

The disease for the most part commences its attack so insidiously, that the patient has no suspicion of the real nature of the case. He feels a troublesome costiveness, which he ascribes to almost every thing rather than the real cause, and endeavours to alleviate it by various kinds of cathartics. These, while they afford temporary relief, add, by the habitual irritation they produce, to the primary and unsuspected malady; and the next symptom perhaps is that of piles, or what is so conceived from a varicose state of the hemorrhoidal vessels, and the natural tendency of all mucous canals to evince most excitement at their extremities.

In the meantime the morbid part of the gut continues to thicken and harden in its coats, its bore diminishes in diameter, and the efforts to expel the recement become more violent. The stools are now of a still slenderer and often of a twisted or serpentine form, and have the appear-

ance of convoluted earth-worms, or butter squeezed by a piston through a confectioner's syringe.

Thus far, however, the constitution suffers perhaps but little; and the patient, to his friends, may appear to be in the zenith of health. But if the rectum be tried by the finger or a bougie, a morbid change of structure will be perceived, that threatens the most alarming results. The sphincters will probably be found pliable and free from disease, and the part of the gut immediately above them, for two, three, or more inches, will be equally healthy; but the stricture, as soon as it is reached, will, perhaps, scarcely admit the passage of the finger, and oppose its entrance by the semblance of a hard cartilaginous ring; or if it be not thus indurated and rendered scirrhus, it may be studded by a circle of tubercles, or intersected by a network of membranous filaments. And if a sound or bougie be passed through the neck of the stricture, another stricture may be found higher up, and again repeated to the sigmoid flexure of the colon; where perhaps the disease originated, and whence it has worked its way downwards; the colon possessing naturally its least diameter at this point, and the feces being here most easily delayed in their progress, not only from this increased narrowness of the passage, but also from the curved line in which they have to move forward into the rectum.

Whether the stricture be thus complicated or not, the narrower its aperture becomes, the greater the difficulty of passing the feces, which necessarily accumulate and distend the bowel above, excite eructations and gripings, and occasionally lay a foundation for that species of colic which we have already described as issuing from this source, under the term *colica constricta*. The feces can now be discharged only in a fluid state; and there is a sanious oozing from the anus, accompanied with a certain degree of tenesmus, which is rather troublesome than severely painful.

"At this period," observes Mr. Copeland, who has admirably described the progress of the disease,* "abscesses very frequently form in the neighbourhood of the anus, and sometimes break into the vagina of the female, and the feces are discharged through the fistulous orifice. In the male, an adhesion takes place to the bladder, and the abscess (*Petit, Œuvres Posthumes*, tom. ii., p. 93) discharges itself with the urine, and sometimes feces and wind are voided by the urethra. But more frequently the matter makes its way through the nates, as in cases of common fistula, for which disease it is not unfrequently treated. The patient often continues a long time in this distressing situation, for none of the vital organs are affected; till, at last, worn out with the pain and the discharge, or perhaps a total obliteration of the rectum, he yields to his fate. This is usually the progress and issue of the disease when it is not early discovered; and, I must confess also, sometimes

* Observations on the Principal Diseases of the Rectum and Anus, sect. i., p. 11.

the termination when it is: that is, when the parts are attacked with cancerous ulceration."

[In one case, however, which the editor attended at Halliford, the tenesmus was particularly severe. The disease, indeed, corresponded very closely to the following description. With the usual symptoms of stricture, there were the most acute lancinating pains in the part, extending through the pelvis to the loins and thighs; and every now and then the pains were followed by a sudden gush of bloody discharge from the bowel. When any feces passed, the suffering was extreme; and for several months previous to the fatal termination of the disorder, there was a peculiarly fetid discharge from the anus. The patient was a gardener, more than seventy years of age; and he did not sink till his stomach became disordered. During the latter stages of the disease, the functions of the bladder were very much disturbed. The passage of a bougie into the rectum could never be endured, and even a clyster-pipe was intolerably painful.

The causes of the present disease are completely unknown. It is generally remarked by writers that it may originate from any kind of irritation of the rectum; yet, without some other circumstances conducive to the changes of structure, forming what is usually called a scirrho-contracted rectum, simple irritation of the bowels will not bring on this afflicting disease. The case is sometimes suspected to arise from a peculiar morbid condition of the mucous glands of the rectum.—(*Salmon, on Stricture of the Rectum*, p. 63.) Dr. Baillie entertained this opinion, which he thought was confirmed by the fact, that such glands are most numerous at the lower part of the gut, where the disease is also most frequent. If this be the case, however, it only refers to the structure in which the disease commences, and throws no light on the cause of its commencement. The probability is, that the complaint is dependant on constitutional causes, like every other form of scirrhus. Desault found the disease to be much more common in the female than the male sex, in the proportion of ten to one: the subjects of it are also mostly advanced in years. This tends to support the opinion already delivered, respecting the operation of constitutional causes. A case was communicated to Dr. Monro, by Dr. Gregory, where the disease was ascribed to the insertion of a fish-bone in the coats of the rectum, as discovered after death.—(See *Monro's Morbid Anat. of the Human Gullet, &c.*, p. 22.) The particulars recorded, however, do not warrant this inference, since the stricture might have occasioned the stoppage of the bone, and not the bone the formation of the stricture. This, at least, is the editor's view of the subject, and it is confirmed by various examples in which cherry-stones or other foreign bodies have been detained in other parts of the intestines by strictures.—(See case by *Salmon*, op. cit., p. 31.) The idea of the disease ever originating from syphilis is now abandoned by every surgeon of judgment. Mr. Salmon refers to two specimens of the disease in an advanced stage:

in both cases the mucous and muscular coats of the bowel have been absorbed, in consequence of the pressure of a new-formed substance, which, in one instance, has made its way into the bladder, and, in the other, into the vagina.—(Op. cit., p. 63.) These two cases, then, present one feature of carcinoma of the breast, namely, that which consists in the substitution of a new-formed substance for the original texture, which is absorbed. The projection of the new mass into the bladder and vagina, however, would rather indicate a character of fungus hæmatodes.]

The existence of transverse filaments, like that of cancer, is generally preceded by scirrhoty, as remarked in the following passage of Dr. Baillie. The scirrhus "sometimes extends over a considerable length of the gut, viz. several inches; but generally it is more circumscribed. The peritoneal, muscular, and internal coats are much thicker and harder than in a natural state. The muscular, too, is subdivided by membranous septa, and the internal coat is sometimes formed into hard, irregular folds. It often happens that the surface of the inner membrane is ulcerated, producing cancer. Every vestige of the natural structure is occasionally lost, and the gut appears changed into a gristly substance." These remarks are strikingly illustrated by well-engraved figures in the author's *Morbid Anatomy*.—(Plate iv.)

In a few cases of irritation, the transverse filaments have been formed before the thickening of the gut has become callous, and have nevertheless been accompanied with all the painful symptoms just noticed. If, in this incipient state of the disease, these filaments be carefully removed, it has often happened that an easy and radical cure has followed in a short period, of which Dr. H. Y. Jameson, of Baltimore, has published a striking and instructive example.—(*American Medical Recorder*, April, 1822.)

Ruysch gives an instance of a scirrhus stricture of the rectum, which produced great agony, and terminated fatally, excited, as he supposed, probably without sufficient grounds, by a stricture of the urethra. On dissection, the pelvis of each kidney, and the middle of the right kidney, were found loaded with calculi; the rectum, through its entire length, was nearly of the thickness of the thumb, and so indurated as to render it difficult to say whether the incrustation should be called flesh or cartilage: the canal was not wider than a straw; and so firmly had the intestine adhered to the sacrum, that it could only be separated by a mallet and chisel, the point of a knife having been previously tried in vain.—(P. 358.)

[When the texture of the scirrho-contracted rectum is considered, it must be confessed that there is not only great difficulty in putting faith in the efficacy of any internal medicines, but also in giving credit to the statements of benefit derived from direct applications to the diseased part itself. Experience must be heard, however, and the authority of Desault can be brought forward in confirmation of the power

of tents and bougies to relieve and even cure this formidable disease. Notwithstanding what was once asserted, pressure will not cure cancer of the breast ; and it is puzzling to understand why it should ever succeed in cancerous affections of the rectum, unless the latter be presumed to be of a different nature from scirrhus affections of other organs. Yet Desault declares that the disease can be cured, and has recorded examples of the successful treatment of what he conceived to be scirrhus of the rectum. It is not every surgeon, however, that bows to this doctrine ; and Professor Gibson delivers his own judgment very unreservedly when he remarks that, whatever may be said to the contrary, genuine scirrhus, or cancer of the rectum, is absolutely incurable.—(*Institutes and Practice of Surgery*, vol. i., p. 293.) A similar prognosis is given by Mr. Salmon.—(*Op. cit.*, p. 64.) In the example which I attended at Halliford, the bougie could never be endured. Some palliation of the sufferings was produced by the exhibition of hyoscyamus, joined with hemlock, opium, or the blue-pill ; and by the occasional use of castor-oil, anodyne clysters, the slipper-bath, and fomentations. Our author, as the annexed remarks show, had confidence in the bougie.]

In the earlier stages of this disease, the steady use of a bougie, firm, but not harsh, and lubricated with oil, of a size adapted to the diameter of the stricture, so that it may press against its sides with a force, short of uneasiness, will afford, in conjunction with gentle laxatives, the best chance of cure, and has in very numerous instances completely succeeded. The bougie may be retained at first for only a few minutes, as, on its earliest use, it will probably give pain, and irritate ; but by degrees it should be borne for a longer period of time, and at length for several hours in a day. The pressure will promote absorption, and consequently reduce the morbid thickness of the coats, and hereby enlarge the diameter of the intestine ; and as this last change occurs and advances, it should gradually be met by a bougie of larger calibre, till the canal is restored to its proper dimensions. And even after this, it will be proper to return to the bougie occasionally, for a few minutes at a time, that there may be no relapse from the existence of a predisposing habit.

Nothing is so well calculated as the bougie, moreover, to break away that network of filaments which, as we have already observed, is sometimes united with an incrustation of the rectum, and spreads from one side of it to another. In this case there will usually be found at first a considerable degree of pain, and sometimes a considerable degree of hemorrhage ; but a courageous perseverance will triumph over these, and amply reward the patient's exertions. And the tubercles, which are so apt to form on the loose and inner coating, will often yield and be carried off by the same means.

When, however, the disease does not yield to this plan, or has reached a more serious stage in its destructive progress, it becomes a direct subject of operative surgery : and a cure may

yet be obtained by a removal of the tubercles by ligature or the knife ; or a division of the thickened ring by a curved and probe-pointed bistoury. When, indeed, the disease is of so complicated a character as to embrace at the same time a contraction of the sphincter, M. Boyer has proposed also to divide this muscle ; and asserts that he has often done it with success. But as it is not the intention of the present work to enter upon the province of practical surgery, I shall not pursue the subject any further.

SPECIES III.

PROCTICA TENESMUS.

STRAINING.

PAINFUL AND PERPETUAL URGENCY TO GO TO STOOL, WITH DEJECTION OF MUCUS ALONE, AND IN SMALL QUANTITY.

WHEN this complaint is idiopathic, it is the result of local irritation, mostly produced by cold ; the passage of acrid stimulating matter from the bowels ; the mechanical pressure of confined enterolithi, or minute scybala ; or an injudicious use of acrid cathartics, especially of aloes, which have a peculiar tendency to stimulate the lower part of the rectum. It is sometimes intolerably vehement, and accompanied with a protrusion of the gut ; the mucous discharge is bloody, and the straining continues long after the intestine has emptied itself of every particle of its contents. And even when the patient has risen from stool, he will still perhaps be tormented with a burning pungent heat, and a perpetual urgency to expulsion. It is this violence of attack, indeed, that chiefly distinguishes this species from the symptomatic straining that occurs in the preceding, which is attended with but little comparative pain, and generally ceases upon the discharge of even a small portion of feces. The constant urgency and torment wear away the sufferer's strength, and sometimes extend the irritation to the bladder.

Most commonly, however, tenesmus is nothing more than a symptomatic affection, excited by some disorder of the bladder, as inflammation in its neck, or a calculus in its cavity ; or by dysentery, chronic diarrhœa, costiveness, piles, worms (especially ascarides), and pregnancy ; or, as just observed, by a stricture of the rectum, or its sphincter.

In all these cases, tenesmus can only be removed by a cure or palliation of the disease on which it is dependant : but where it is an idiopathic affection, a more direct course of treatment may be adverted to. If a lodgment of acrid materials form the cause, these should be freely discharged, and the irritation they have excited be subdued by bleeding with leeches, and a local application of opium, intermixed with soap and wax to prevent its being too quickly dissolved ; or by small doses of ipecacuanha, or of Dover's powder. In very painful extremes, opiate and mucilaginous injections will often alleviate the distress ; or Goulard

water with oil. Laudanum in a solution of starch is frequently employed with great benefit as a clyster; or the extract of opium may be introduced into the rectum as a suppository.

SPECIES IV.

PROCTICA MARISCA.

PILES.

LIVID AND PAINFUL TUBERCLES OR EXCRESCENCES ON THE VERGE OF THE ANUS; USUALLY WITH A DISCHARGE OF MUCUS OR BLOOD.

THIS species has generally been described by modern writers under the name of *hæmorrhoids*, whence *hemerods* or *emruds*, in old English, and *hemorrhoids* in the English of our own day. Now, the literal meaning of *hæmorrhoids*, *αιμορροΐς*, is “flux of blood;” and in this sense the term was used by the Greek and Roman writers, sometimes generally, and sometimes with a special application of it to menstruation, and particularly profuse menstruation, or uterine hemorrhage, but never with a special reference to hemorrhage from the anus, as I have already remarked in the Preliminary Dissertation to the volume of Nosology (page 55), to which I refer the reader; and hence again, Aristotle denominates, by the term *hæmorrhoids*, a serpent, whose bite was said to be succeeded by a violent and fatal flow of blood from the bitten vessels.—(*De Partibus Animal.*, lib. iii.) The name is, therefore, highly inadequate to the purpose of expressing, with any degree of clearness, tubercles, or even discharges from the anus; yet it becomes not only inadequate but absurd, when employed generally to indicate a family of diseases, some of which have a discharge of mucus instead of a discharge of blood, and others no discharge of any kind.

For these reasons, as well as others stated at large in the comment to the volume of Nosology, I have deemed it expedient to adopt the Latin term *marisca* in the stead of *hæmorrhoids*; and to limit the genus to those tumours or excrescences about the verge of the anus, which, under every view of the disease, form its prominent character.

These enlargements commonly, and perhaps in every instance, derive their existence from a turgid and varicose state of the anal or hemorrhoidal veins; for, in their simplest forms, piles consist of nothing more than varices of these veins, covered with a slight thickening of the inner membrane of the rectum, as Dr. Baillie has sufficiently shown in his illustrative plates.—(*Morbid Anat.*, pl. v., fig. 2, 3, p. 78.)

[When piles are discriminated from mere swellings of the veins, termed *hemorrhoidal varices*, to which the practice of excision is dangerous, they are first seen in the form of small fleshy tubercles, generally of a brownish or pale red colour, and either situated within the anus, or descending from the rectum. They have rather a solid and spongy feel, and when cut into, present a surface more or less compact and bloody, from which blood oozes, leaving the texture pale and more relaxed. When

VOL. I.—N

they are more external, they are paler, and generally also more elastic and transparent; and they appear and disappear more quickly than the former. Piles very often contain a central cavity, filled with fluid or coagulated blood, and lined with either a smooth or granulated cyst. By means of fine anatomical injections, a few minute vessels may be demonstrated, through which the blood exudes into the central cavity, but no direct connexion exists with any of the larger vessels. The cavity usually does not exceed the size of a pea; but it is sometimes large enough to hold several drachms of blood. More generally, however, there is no regular cyst, but the substance of the tumour is infiltrated with blood, which eventually becomes dark and coagulated. Common piles subside and return at uncertain periods, and they become larger and firmer, in proportion to the frequency of the attack. Often, however, after some discharge of blood, they collapse, their cavity seems to be obliterated (See *Sir A. Cooper's Lectures*, vol. ii., p. 336), and they leave merely pendulous flaps, formed of stretched skin. But when they have been strangulated for some time by the pressure of the sphincter, repeatedly gorged with fluids, or been of very long standing, they acquire more solidity, and become permanent, varying but little in size, and forming a source of almost constant pain, from protrusion, inflammation, or ulceration; or, by occasioning a distressing prolapsus of the anus. This permanent state of the tumours is referred by Mr. Calvert partly to the development of the capillary vessels, by which the interstices are gradually obliterated, and partly to the coagulation and organization of the effused blood. Hence the production of condylomatous tumours, and what are termed hemorrhoidal excrescences, all of which are solid, and can only be removed by the knife or ligature. With respect to this description the editor begs to observe, that all the several forms of piles are generally conceived, and probably with correctness, to be originally mere swellings of veins, whatever may be the solidity they afterward acquire, or the seemingly small or indirect communication of their cavity with the venous trunks.]

From local irritation, produced by indurated and retained feces, or purgative stimulants, and especially aloetic purgatives; or from an undue determination of the blood to the hemorrhoidal vessels, by excessive walking or riding; or their turgescence, arising from enlargement of the liver or adjoining viscera; from the pressure of the gravid uterus on the pelvic veins; from the irritation of stone in the bladder, and often from a peculiarity of the constitution itself; the extremities of the hemorrhoidal veins are apt to become varicose, and swell into tumours; frequently accompanied with inflammatory action in the surrounding mucous follicles; the swellings enlarge gradually into caruncular excrescences, pea-sized, fig-sized, or of various other figures, sprouting about the verge of the anus, within or without; and are often so painful as to prevent either walking or sitting. Some-

times the caruncles thus produced are hard, florid, incompressible, without discharge, and intolerably sore to the touch. Sometimes irritation induces a secretion of whitish mucus from the neighbouring glands. Sometimes the hemorrhoidal vessels themselves, that form or supply the sprouting tumours, are so distended as to burst and bleed freely. And occasionally the inflammatory action gives rise to the formation of caruncles of different shapes and sizes, sometimes spreading about the perinæum, but mostly existing within the verge of the anus. Whence we obtain four distinct varieties, as follow :—

α Cœca.	Blind piles.
β Mucosa.	White piles.
γ Cruenta.	Bleeding piles.
δ Caruncularis.	Caruncular piles.

We have just observed, that piles in their simplest state consist of nothing more than varicose tumours of the anal veins, covered with a slight thickening of the inner membrane of the rectum : and I have pointed out a variety of causes predisposing to such tumours. The trivial term *cæca*, or *blind*, though not peculiarly expressive of the idea intended to be conveyed, has been applied for ages to the first example before us, which is void of every kind of discharge, whether mucous or sanguineous, and has no *eyelet* or aperture through which such discharge may flow, and carry off the accumulation. Mariscal tumours, Mr. Copeland conceives, are most common in persons who possess a very strong action of the sphincter ani, and are hence habitually predisposed to a spasmodic stricture of the rectum. In such persons he supposes, that on every expulsion of the feces, the internal membrane of the rectum, together with the vessels it contains, is protruded, and caught or detained, and some of its veins strangled by the forcible constriction of the muscle. That this is a frequent cause of piles I have no doubt, though, from their occurring in such numerous instances in persons of lax fibres and debilitated habits, it appears to me to operate less frequently than is suspected by Mr. Copeland.

Mariscal excrescences are likely to be the hardest, the sorest, and the most florid of the whole, when the result of such a cause. Where they proceed from a mere relaxation of the vascular system, or a diseased state of the larger abdominal viscera, they will sometimes acquire a considerable bulk without being highly painful ; but in this case, they are usually soft and compressible.

It will be better and more compendious to take a survey of the other varieties, before we proceed to the curative intention.

In some persons, the mucous follicles of the interior membrane of the rectum are far more easily excited to secretion than in others ; as we see in many individuals the mucous membrane of the nostrils pour fourth a readier and more abundant defluxion. It is in this state that the tumours assume the name of *WHITE* or *MUCOUS PILES* ; and as the excretories thus easily evae-

uate themselves, there is much less soreness and irritation, and the tumours or tubercles are comparatively pale as well as moist ; and, though often not admitting of so rapid a cure as some of the other varieties, are considerably less distressing.

It often happens that, from distention, the walls of the anal varices give way, and form *BLEEDING PILES*. Yet it does not always follow that blood is hereby discharged, or the tumours are diminished. For it occasionally occurs that the surrounding membrane does not give way at the same time, and consequently that the extravasated blood is accumulated in the contiguous cellular substance, and the tumours, instead of diminishing, increase from the size of a pea to that of a pullet's egg, block up the entire passage of the rectum, and are a source of very great evil. If, however, this take place at some distance above the sphincter ani, where the parts yield more easily, the pain may not be excessive ; but if these enlarged tumours be seated on the sphincter, or within the range of its contractile influence, the torment induced is often intolerable.

From this difference of seat, piles from of old have been denominated external and internal ; and it was imagined by Dr. Stahl and his disciples, that the former were produced by a gorged state of branches from the vena cava, and the latter from a like congestion in branches of the vena portarum. No benefit, however, can possibly result from such a distinction ; nor is the distinction itself founded in fact : for all the arteries and veins that appertain to the lower part of the rectum arise so diversely, and anastomose so frequently, that an affection of one must be communicated to another, and the general result be participated by the whole.

In most cases, however, in which the varicose vessels burst, the distended and attenuated membrane that surrounds them bursts at the same time, and the blood flows externally. The hemorrhage is in some cases very considerable : and as this variety, more than any of the others, is apt to run into a habit, the constitution occasionally becomes greatly debilitated, and often dropsical ; and the hemorrhage has, in a few instances, been so profuse as to endanger life. When, moreover, a hemorrhoidal habit is once established, the flux, even if it do not undermine the health by its quantity, often becomes periodical, enters into the chain of constitutional actions, and becomes a regular condition of the corporeal weal ; so that its suppression is attended with serious mischief.

It often happens, and especially during the first variety, which evinces the highest degree of inflammation, that an effusion of coagulable lymph takes place around the marital varix, which terminates in vascularity, and the production of a fleshy substance, that still continues even after the overloaded vessels have recovered their proper diameter and tone. It is these *CARUNCLES*, which are rather the sequels of piles than piles themselves, that constitute the fourth variety. They are of different shapes and sizes, bulbous, soft, and compressible, red or reddish ;

and not unfrequently the base shrivels into a narrow neck, while the body of the caruncle enlarges and elongates so as to assume a polypous appearance.

Caruncles, not very unlike, are frequently found sprouting from the cuticle or cutis that surrounds the anus, often assuming the appearance and having much of the nature of warts; solitary or clustering, with a broad or narrow base; and which are sometimes regarded as piles, but are altogether of a different origin.

In attempting a cure of this complaint, our first attention must be directed to the cause, as far as we can ascertain it. If the bowels be habitually constive, gentle laxatives should be employed daily; and where the complaint has been induced by excessive walking or other muscular exertion, quiet and a recumbent position must be sedulously enjoined. The laxatives in either case may be the cassia or senna confection; oil of castor, where it will sit easy on the stomach, with the addition of a little spirit, which is its best corrective; and sulphur. Sulphur has long been regarded as a specific for piles; but I do not know that it possesses any other virtue than that of being a mild aperient. It seems, however, to be an aperient peculiarly calculated to act upon the large intestines; since, being soluble with difficulty in animal fluids, it dissolves slowly, and does not spend itself till it has descended to a considerable depth in the alvine canal.

Dr. Cullen was in the habit of employing in this complaint the balsam of copayva. After observing that, like turpentine, it provokes aperient, he proceeds as follows:—"Whether a certain effect of balsam of copayva is to be imputed to this operation, I cannot determine; but must observe, that I have learned from an empirical practitioner, that it gives relief in hemorrhoidal affections, and I have frequently employed it with success."—(*Mat. Med.*, part ii., cap. v., p. 190.) His dose was from twenty to forty drops, properly mixed with powdered sugar, once or twice a day.

I have tried this medicine often, and when it has appeared useful, it has been chiefly in the case of mucous piles; I am hence induced to ascribe its salutary effect rather to the common principle, on which it is well known to act in irritations of mucous membranes generally, than to its laxative power.

Where the pain and tension are very distressing, relaxant cataplasms and fomentations are generally advisable. The common bread poultice, with a solution of opium, is one of the best.

The butter of chocolate may be advantageously employed for the same purpose, either as a most mild emollient ointment, in the form of a suppository, with a small portion of spermaceti, or as an exquisitely bland bougie with a nucleus of cotton.

If we can scarcely refer the disease to a gorged or obstructed state of the liver, or any other abdominal viscus, the purgatives we employ may be of a more active kind, and a free use of the lancet should precede them. And if the piles should depend upon a strong entonic action of

the sphincter ani, bleeding from the arm will also be highly useful; but the local application of leeches will answer better.

In every variety, indeed, in which there is much heat, hardness, and irritation, leeches will be found an important remedy; and when these symptoms are hereby removed or mitigated, we should have recourse to local tonics and astringents. The patient may sit frequently in a bidet of cold water, or apply cataplasms of cold water and crumb of bread; or, if the tumours be seated above the sphincter, use injections of cold water. With the water we may often advantageously intermix the earthy or metallic astringents, as alum, sulphate of zinc, or the superacetate of lead. Where the tubercles are not very sore, they will often yield to a layer of gypsum, or, what is better, fullers' earth, which, however, should be rubbed into as soft a paste as possible. This is a remedy which has been long employed on the continent (*Eph. Nat. Cur.*, Dec. iii., Ann. iii., obs. 162); and I have sometimes prescribed it with singular success, and have known piles, when softish and compressible, removed by it in a single night.

Several vegetable astringents are well entitled to our attention for the same purpose; and especially the powder or extract of catechu, which I have known to be serviceable to external tubercles in the form of ointment, and to internal ones in the form of an injection. And Dr. Cullen speaks with equal favour of finely pounded oak-galls, in cases where the disease is not connected with the general habit.—(*Mat. Med.*, part ii., chap. i., p. 46.) A mild solution of the nitrate of silver will, however, often be preferable to any other astringent.

If these should fail, the pressure of bougies should be had recourse to, and especially in piles supposed to be produced by a constitutional entonic constriction of the sphincter muscle; for, in this case, it will have a tendency to remedy both the cause and effect at the same time. Suppositories and bougies for this purpose are of long standing and high recommendation. With a view of uniting the two advantages of pressure and cold, they were formerly recommended to be made of slices of any of the cucurbitaceous fruits, as cucumber, gourd, or melon (*Morgagni, De Sed. et Caus. Morb.*, Ep. xxxii., art. 12; *Lange, Miscell. Verit.*, p. 104); but none of these are sufficiently stiff to obtain an adequate expansile force; and hence the large rectum bougies in common use have been advised. I have sometimes seen them made of very finely polished ivory, of a conic shape, about the length of the forefinger, with a ringlet at the base; and the exquisite smoothness and equality of pressure they possess peculiarly fit them for the purpose. Mr. Bell proposes a bougie or tent formed of a silver tube, wrapped round with soft linen, or a piece of sheep's gut tied at one end, and then pushed to a sufficient height into the rectum, and forcibly distended with water.—(*Surgery*, vol. ii., chap. xvi., p. 259.)

Occasionally nature has effected a cure; and the effused substance has been absorbed without any artificial means whatever (*Marignies*,

Journ. de Méd., tom. xxxii.); but more generally neglect produces the most lamentable consequences, and especially fistulous ulcers of very difficult removal; which have sometimes indeed, as Mr. Gooch has sufficiently exemplified, worn a sinuous path, and opened into the vagina.—(*Cases*, &c., p. 249.) And hence, if none of the preceding means should be found to answer, and especially if the tubercles be extremely painful and distressing, they should be removed with all expedition by ligature, caustic, or the knife. Of these, the use of caustic is by far the most unadvisable, whether actual or potential. Of the other two methods, it is not easy to say which is the preferable; and hence each has been in favour with different practitioners. The chief disadvantage of the ligature is, that, by tying up the surrounding membrane of the intestine along with the immediate substance of the tumour, a very high degree of sympathetic irritation, and even inflammation, has at times been excited over the whole range of the intestinal canal, and even the perineum, and to a degree that has in some instances proved fatal: the ligature appearing to act, as M. Petit observes (*Œuvres Posthumes*, tom. ii.), in the same manner as the pressure of the tendinous rings of the abdominal muscles in cases of strangulated hernia; and producing the same effects of incessant hiccough, vomiting, abdominal inflammation, and gangrene. This, however, rarely occurs except when the ligature is applied round several tumours at the same time, or during their inflamed state; for if only one be operated upon at once, and the rest in succession, the irritation has not been generally extensive, or of longer duration than two or three days. And perhaps even this might be avoided, by denuding the tumour of its external covering, as M. Petit has proposed.

The chief difficulty that attends the operation of excision is a very troublesome, obstinate, and debilitating hemorrhage, which is apt to follow, and which many surgeons have found very hard to restrain; chiefly, perhaps, because the veins of the abdominal viscera are destitute of valves. Sir Astley Cooper has once or twice found it prove fatal; and hence, though in his earlier years an advocate for excision, he afterward gave a preference to the ligature.—(*Lectures*, &c., vol. ii., p. 342, 8vo., 1825.) Excision, therefore, is chiefly calculated for the caruncular variety, and in such cases is far preferable to the ligature; but where we have reason to believe that the varicose vessels are of a large diameter, the knife should not be had recourse to. [Mr. Calvert, whose observations on piles are judicious, makes a practical distinction between the firmer swellings, whose cavity or cells have but a small or indirect communication with the large veins, and other tumours, which he calls hemorrhoidal varices, and consist entirely of dilated veins. The latter are the cases to which the practice is inapplicable. Hemorrhoidal varices are generally of a dark or bluish colour, soft and elastic to the touch, resembling in this respect ripe grapes; and, when compressed by the finger, they are evidently diminished, but return to their former state as soon as the pressure is

removed. Their shape is also very different from that of other hemorrhoidal tumours; being broader at the base, rounder, and sometimes distributed in irregular clusters, like similar affections of the *venæ saphenæ*. Tumours may also be presumed to be of this nature, when they can be traced from the anus far up the rectum.—(See *Calvert on Hemorrhoids*, &c., 8vo., Lond., 1824.)] Cutaneous excrescences about the anus, erroneously denominated piles by the vulgar, may be taken off with a knife or a pair of scissors, in any number, or to any extent, without reserve.

SPECIES V.

PROCTICA EXANIA.

FALLING DOWN OF THE FUNDAMENT.

INVERSION AND PROLAPSE OF THE VILLOUS TUNIC OF THE RECTUM, FROM ENTONY OR RELAXATION OF THE SPHINCTER.

This is a very common and a very troublesome disease: but it is capable of a perfect cure in most cases, and of great relief perhaps in all. There are two varieties of it, proceeding from the two opposite causes of atony and entony, and which demand a very different mode of treatment.

a Atonica.	Relaxed Exania.
β Spasmodica.	Spasmodic Exania.

Where the action of the sphincter is feeble, it collapses readily, and often imperfectly; and the part of the rectum that always descends towards the verge of the anus upon a protrusion of the feces, instead of being retracted with elasticity, remains exposed, or ascends imperfectly. Yet there is little pain or tumour, and reduction is easy. Under such circumstances, exania, or a prolapse of the inner membrane of the rectum, will often occur on the slightest defective effort: but if, at the same time, the rectum be labouring under any morbid irritability from the stimulus of scybalous feces, ascariides, or purgatives, the protrusion will be greatly exacerbated, a much larger portion of the gut will be exposed, and its retrocession will be more difficult. Sometimes, indeed, the portion exposed has been very considerable; for Morgagni relates a case, in which the valvulae of the colon were hereby brought into view (*De Sed.*, &c., xxxiii., lxxv. 6); and Hagen (*In Schroeder Verm. Schr.*, band i., p. 609, 1778) another, in which there was a prolapse of the entire colon itself.

Common, however, as is the disease before us from local or general debility, it is perhaps still more frequent from that habitual or accidental excess of contractile action in the sphincter of the anus.* If the tumour remain down, it

* The correctness of this explanation may be doubted: the case here described, probably, does not arise from excessive action of the sphincter, but rather from a bad habit of sitting long at stool, and from the protracted efforts of straining, in which many muscles tend to propel the rectum and its contents downwards, the sphincter and cellular connexions of the gut becoming thereby

becomes large, irritable, and painful; and, if assistance be not obtained soon, a violent and serious inflammation will be sure to supervene.

In the atonic prolapse, but little aid is necessary, in ordinary cases, to return the protruded part. A simple pressure of the hand against the denuded part of the intestines, or sitting upon a plain and hard seat, will ordinarily be sufficient; and, if not, an introduction of the forefinger up the anus will always succeed. Hence patients, labouring under this variety, commonly return the gut themselves after evacuation; and in many instances it will ascend of its own accord.

The chief difficulty is in effecting a cure; which can only be accomplished in two ways: by invigorating and bracing the loose and relaxed membrane, or giving it an adhesion to the subjacent cellular substance from which it is detached.

The first may sometimes be accomplished by local tonics and astringents; as cold water dashed against the buttocks, injections of cold water, solutions of alum, or sulphate of zinc, or an infusion of catechu, or gallnuts.

The second can only be accomplished by artificially exciting a slight continuous inflammation in the cellular substance, by slipping off a small piece of the protruded membrane, as recommended by Mr. Hey, or passing a ligature through a small portion of it, and letting it remain after the return of the membrane, till the inflammatory action has commenced; by which means a radical cure is often obtained, in the

same manner as a like cure is effected in scrotal dropsy, by hooking forwards and cutting off a small piece of the tunica vaginalis after evacuating the water. Mr. Copeland has employed this method in various instances, and with all desirable success.

Where there is a prolapse of the upper part of the rectum, or of the colon, the disease is of a different kind; for, in this case, the entire parietes descend, and the upper part is invaginated in the lower, as in an intussusception of the smaller intestines; but with less mischief in the present instance, as there is more space for play, and as the intestinal canal evinces less sensibility, and consequently admits of harsher treatment, in its progress towards its lower extremity. In this case, the whole we can aim at is to strengthen the fibres of the relaxed bowel, and restore them to a healthy elasticity by the use of tonic and astringent injections.

In entonic or spasmodic exania, it will be often necessary to apply leeches, and to bleed pretty freely, before a reduction can be obtained. After which, as this is chiefly a result of spasmodic stricture, or depends upon like causes, the mode of treatment already recommended for the one will be the best plan to be pursued for the other.

This complaint is also found occasionally as an effect in lithiasis, proctica marisca, helminthia podicis, scirrhus of the prostate gland, fistula ani, and other affections of the uterus, vagina, bladder, and neighbouring organs.

ORDER II.

SPLANCHNICA.

DISEASES AFFECTING THE COLLAGENOUS VISCERA.

DISQUIET OR DISEASED ACTION IN THE ORGANS AUXILIARY TO THE DIGESTIVE PROCESS, WITHOUT PRIMARY INFLAMMATION.

The order of diseases upon which we now enter, is in the present classification denominated SPLANCHNICA (ΣΠΛΑΓΧΝΙΚΑ), as primarily affecting, and being seated in, the viscera that are directly adjuvant to the function of digestion. The term SPLANCHNICA is thus reduced to its more limited and emphatic sense; for, in a loose and broader signification, it imports, like its Latin synonyme *viscera*, all the larger bowels or internal organs, to whatever cavity they appertain, and consequently includes the brain: but in its stricter and more exact

meaning, it was formerly confined to those of the lower and upper belly, comprising what we colloquially call the ENTRAILS; and more especially those which were consulted by the aruspices, and constituted the chief parts of the sacrifice: in which sense it is mostly employed by Homer, and the Greek tragedians.

The organs, therefore, to which the term is here intended to be applied (for the alvine canal forms the subject of the first order), are the liver, spleen, pancreas, mesentery, and omentum; and, as in the physiological proem to the class before us, we took a general survey of the structure of these organs; and, so far as we are acquainted with them, of the parts they respectively fulfil in accomplishing the economy of digestion; we shall proceed, without farther delay, to a consideration of the diseases which belong to them under the proposed arrangement.

The order embraces four genera:

- | | |
|-------------------|-----------------------|
| I. Icterus. | Yellow Jaundice. |
| II. Melæna. | Black Jaundice. |
| III. Chololithus. | Gall Stone. |
| IV. Parabysma. | Visceral Turgescence. |

Of these, several comprise numerous species, which will be noticed in their respective places.

in time so weakened, that a prolapsus ani ensues. In the production of the first variety described by the author, spasm of muscles has a share, particularly when there is irritation about the rectum from piles, or other cause; though, of course, the repeated protrusions will naturally, at last, weaken the sphincter.—ED.

GENUS I.
ICTERUS.

YELLOW JAUNDICE.

YELLOWNESS OF THE EYES AND SKIN; WHITE FECES; URINE SAFFRON-COLOURED, AND COMMUNICATING A SAFFRON DYE; THE COURSE OF THE BILE OBSTRUCTED.

THIS disorder was by the Greeks denominated ICTERUS (ΙΚΤΕΡΟΣ) as above, and by the Romans, as Celsus particularly notices, Morbus arquatus, or Morbus regius: but on what account either of these names has been given to it, we have no satisfactory information. Arquus means a rainbow, which requires more explanation than has hitherto been given; and the meaning of regius, as expounded by Celsus, will, I apprehend, content very few. "Its cure," says he, "is to be attempted by exertions of every kind, luso, joco, ludis, lascivia, per quæ mens exilaretur; OB QUÆ REGIUS MORBUS DICTUS VIDETUR" (*Medicin.*, lib. iii., sect. xxiv.):—"by play, jests, sports, and dalliance, on which account it seems to be called Morbus regius, or the royal disease." It has also been named by many writers, ancient as well as modern, *Aurigo*, evidently from its golden hue. But, of the origin or meaning of icterus, we are left altogether in the dark by the critics and lexicographers. It appears to the present author, however, probable, if he may venture upon a subject which has hitherto been tried in vain, that all these terms are expressive of a common idea; and, though not derived from a common root, are employed as equivalents to express its meaning. Icterus (*ἰκτερος*), as it seems to him, is the Hebrew term כֶּתֶר with a formative י producing כִּתֶּר or "icter," and importing, as a verb, "to surround, circumsfuse, encompass;" and, as a noun, "a royal crown, or golden diadem." Icterus was a term also given to the golden thrush or golden pheasant, on account of its golden plumage: and hence the bird was fabled to be connected with the disease; and it was believed, according to Pliny, that if a person labouring under the jaundice should look at the pheasant, the bird would die, and the patient recover. Regius, arquatus, aurigo, are not indeed univocal, but very clearly equivalents, and equally import gold, golden crown, golden bow, or circumfusion; the colour of the disease, and its encompassing the body. There are other diseases however that produce or are accompanied with a yellow tinge of the surface, as well as jaundice; as aurigo (Class vi., Ord. iii., Gen. x., Spe. iv.), and sometimes porphyra or scurvy. Frank mentions a case of the latter, in which there was an intense yellowness of the whole skin, chiefly proceeding from broad maculæ, even to the palms of the hands and soles of the feet.—(*De Cur. Hom. Morb. Epit.*, tom. vi., lib. 6.) But in all these cases, the albuginea is little or not at all affected, and the urine does not communicate the saffron dye of jaundice.

There is, however, a far more important inquiry immediately connected with this subject, which I am afraid will be still less easily settled. We are sufficiently acquainted with the seat of

jaundice, which is the liver, and of its proximate cause, which consists in an impeded flow of the bile; but who shall explain to us the real use of the bile, or even the final use of the liver that secretes it? Considering the large size of the liver in all animals that possess it, and, at the same time, how generally it is possessed, being to all red-blooded animals as common as the heart itself, there can be no doubt that it is of great importance in the animal economy, notwithstanding our uncertainty of the part it performs.

Even below the rank of red-blooded animals, we often discover it, and of great extent; as in the snail, oyster, and muscle; and frequently, too, where we cannot trace an organ answerable in structure and appearance to the liver, we are obliged to admit the existence of an organ that supplies its place; for there are many insects, as the larvæ of the *cynips querci*, or gall-fly, and that of the *curculio nucis*, or nut-weevil, that secrete bile in such quantity as to tinge with a brownish yellow the tender branch, nut, or other substance in which they find a habitation, and to give it a taste as bitter as ox-gall.

The direct and obvious office of the liver is the secretion of bile, which, in most animals, is suffered to accumulate in a pear-shaped reservoir, adhering to its concave surface, and denominated a gall-bladder. Yet, in many animals, even of different classes, we perceive no such reservoir, as the elephant, rhinoceros, stag, camel, goat, horse, trichecus, porpoise, rat, ostrich, and parrot: while we do not know of a reptile that is destitute of it. Upon the whole, however, it may be observed, that a gall-bladder is common to all carnivorous animals possessing a liver, and that it seems to be only wanting in those that feed on vegetables alone. Yet, while we see the distinction, we are ignorant of its cause, and incapable of applying it. In the human subject, it has sometimes also been wanting,* of which Dr. Cholmeley gives an example (*Med. Trans.*, vol. vi., art. 4): but such a deficiency has mostly occurred in infants who have perished soon after birth; before which period, as there is no transit of feces through the intestinal canal, and perhaps no peristaltic action, it does not appear to be necessary. Perhaps, indeed, antecedently to birth, there is no bile secreted. In the case related by Dr. Cholmeley, although the whole of the bile, as fast as it was secreted, seems to have been carried back into the system, the sallowness of the skin is not noticed to have occurred till the day after birth; from which time the child exhibited a deeper and deeper hue, till it died of convulsions at the end of five weeks.

[The want of a gall-bladder does not always dangerously impair the health (*Meckel's Anat.*, vol. iii., p. 312); and an example in which a person, with such malformation, reached the adult state, has been lately recorded.—(*Mém. de Méd. Mil.*, tom. xx., p. 406.) Cats bear the removal of the gall-bladder without fatal con-

* Olivier, note sur l'atrophie de la vésicule biliaire, in *Archiv. Gén. de Méd.*, tom. v., p. 196.

sequences.—(*Sir E. Home, Phil. Trans.*, 1813, part ii.)]

It was stated in the physiological proem, that one supposed use of the bile is, to maintain the peristaltic action of the bowels. Yet Sir Everard Home (*Phil. Trans.*, 1813, pp. 156, 157) has given an example of a child that fed heartily, seemed to digest its food well, and had regular stools, and was nevertheless without a gall-bladder, or even a duct of any kind leading from the liver to the duodenum.*

There are also a few other circumstances relating to the bile, that yet stand in need of explanation. The hepatic bile, or that secreted into the hepatic duct, is mild and sweet; the bile found in the gall-bladder is pungent and bitter; whence we might infer, that it is the gall-bladder that secretes the bitter principle. Yet, in children, the gall-bladder bile is as sweet as that of the hepatic duct; and in various insects, as we have already seen, a bile powerfully bitter is secreted without either gall-bladder or liver. Who shall develop the cause of these discrepancies? Who shall unfold to us the use of the bitter principle of the bile, or explain why it is necessary to the animal economy in an adult state, and not necessary in a state of infancy? †

Yet, whatever be the use of the bile, or the office of the liver, we know that the general symptoms of jaundice depend upon an obstruction to the flow of the bile into the alvine canal, and its retrograde passage into the blood. [Thus in animals jaundice may be produced by applying a ligature to the ductus choledochus; and, in the human subject, dissection has frequently proved its origin from the direct or indirect pressure of various swellings and indurations, either of the pancreas, stomach, spleen, omentum, and other organs, against the biliary ducts. The

jaundice occasionally arising in pregnancy, is sometimes ascribed to the pressure of the gravid uterus on the same canal, and sometimes to a plethoric state of the system, and of the liver in particular, in consequence of the suppression of the menses, which last opinion was espoused by Sauvages, Portal, and Powell. Dr. Elliotson has frequently seen jaundice in pregnancy; not however as the result of pregnancy, but of inflammation of the liver, and which subsided under the treatment for common inflammation, while the pregnancy went on.—(*Med. Gazette for 1832-3*, p. 488.) Whatever will produce hepatitis, or great congestion of the liver, will bring on jaundice.] It has been supposed, indeed, that the bile might, after entering into the intestines, be absorbed and carried into the blood, and by this means produce a jaundice, and a jaundiced hue, without any obstruction to its flow into the intestinal channel. But, in this case, it seems impossible that the stools should not be tinged with a yellow, instead of presenting a white hue, which is one of the common characters of the disease.* In order to constitute jaundice, there must generally therefore be some obstruction to the passage of the bile through its proper ducts into the intestinal canal. And this obstruction may proceed from five sources, each of which may be accompanied with peculiar symptoms, and consequently furnish us with the five following species:—

1. Icterus Cholæus. Biliary Jaundice.
2. ——— Chololithicus. Gall-stone Jaundice.
3. ——— Spasmodicus. Spasmodic Jaundice.
4. ——— Hepaticus. Hepatic Jaundice.
5. ——— Infantum. Jaundice of Infants.

The disease is also found symptomatically in pregnancy, colic, and fevers of various kinds; especially *cpanetus icterodes*, or yellow fever. ‡ [It is generally a sporadical complaint, but instances of its being epidemic, particularly at the termination of campaigns, in wet autumnal seasons, and also of its being endemic, are recorded.‡ The disease appears to have been

* The daily escape of a considerable quantity of bile through a fistulous opening in the parietes of the abdomen, has occurred without serious impairment of the appetite, the digestion, or the health in general. This is a curious fact, and deserves to be well considered in every physiological view of the hepatic system. Dr. Abercrombie visited, along with Mr. Lizars, a man, about fifty, who had had a biliary fistula for nearly four years. The complaint began with pain in the region of the liver, accompanied by vomiting and jaundice. After these symptoms had continued about three weeks, a tumour formed in the region of the gall-bladder, which was opened, and discharged much fluid of a mixed green and yellow colour, and some small biliary calculi. This opening closed, but another soon took place, which has continued to discharge ever since. The discharge varies in quantity, but is often so profuse as in a very short time to wet the patient's clothes as far as his knee, and in the night, to soak through his bed. Mr. Lizars at one time collected, in the course of fifteen or twenty minutes, about four ounces of a fluid, which on chymical examination exhibited all the properties of pure bile. The man has every appearance of good health, and except the fistulous opening, there is no appearance of disease in the region of the liver. His appetite and digestion are good, and the evacuations of a natural appearance.—See Abercrombie on Diseases of the Stomach, &c., p. 395.—Edp.

* Exceptions are occasionally met with, in which the feces are not white. Bile passes into the intestines; but so much is secreted, that all does not escape, and a portion goes into the circulation. It is conceivable then, that jaundice may arise from an excess of bile. This view, however, is sometimes regarded as hypothetical: thus, Dr. Abercrombie does not place confidence in morbid viscosity of the bile, spasm of the ducts, overflow of the bile, and what has been termed bilious congestion, as the causes of jaundice.—See Pathol. and Pract. Researches on Diseases of the Stomach, &c., p. 394, ed. 2.

† The colour of the skin in yellow fever is not always regarded as the effect of jaundice. “The yellowness in this case is not universal; it occurs particularly about the neck; and it appears rather to arise from a disordered state of the blood, or an altered condition of the blood as to some of its constituents, exactly as we see it in bruises.”—See Elliotson in Med. Gaz. for 1832-3, p. 487.

‡ See Monro on the Health of Soldiers, 2 vols. 8vo., 1780.—Pringle on Diseases of the Army, Edin., 1810.—Alibert, Nosologie Naturelle, &c., 4to., Paris, 1817, &c.

epidemic at Cronstadt in 1784 and 1785, and at Geneva in 1814. In the latter city, it occurred after the hot weather of summer, being in some cases combined with a bilious fever; in others, not associated with any other manifest disorder. —(*Dict. des Sc. Méd.*, tom. xxiii., p. 414.) Persons who have been in warm climates are more predisposed to the disease than others.]

SPECIES I.

ICTERUS CHOLÆUS. BILIARY JAUNDICE.

THE COURSE OF THE BILE OBSTRUCTED; GENERAL LANGUOR, NAUSEA, DYSPEPSY, AND OCCASIONAL PAIN OR UNEASINESS AT THE STOMACH.

THE specific term cholæus (χολαῖος) is here restored from the Greek writers, among whom it has been common from the time of Hippocrates.

Dr. Cullen has not noticed this species: but it occurs in Bonet, Amatus Lusitanus, Forestus, Sauvages, and most of the later writers. It is easy, indeed, to conceive that bile may become inspissated from various causes, and particularly from an absorption of its aqueous or thinner parts, by the lymphatics of the ducts themselves, or of the gall-bladder; from an augmented secretion of the albumen, or, as Berzelius considers it, the mucus of the gall-bladder dissolved in the bile; and from too viscid a texture of the bile, in its secretion in the liver. And, in effect, there are few observant practitioners but must have remarked, that the evacuations, whether by the mouth or the anus, when the obstruction is just removed, consist at times of nearly pure bile, peculiarly tenacious and high-coloured.

[After the bile is secreted, if the hepatic or the common duct be obstructed, so that the passage of this fluid into the duodenum be prevented, it regurgitates into the liver, and is taken up by the absorbent vessels, and carried into the mass of the circulating blood,* in the serum of which it becomes dissolved, and thus gives it its own yellow colour. The blood, thus

tinged, carries the die with it to every part of the body, and hence the general hue of jaundice is produced. It would seem, however, that the bile, in a liver, distended from obstruction of the ducts, is not only taken up by the absorbents, but it is also forced into the mouths of the hepatic veins. In dissections, Dr. Saunders and Dr. Powell both notice bile in the thoracic duct, and the first of these physicians found the serum of the hepatic veins in a dog, in which jaundice had been a short time before produced by a ligature on the common biliary duct, evidently more loaded with the colouring part of the bile, than the serum in other veins.* When the bile reaches the circulation, the intensity of tinge which different parts receive, will be in proportion to their vascularity, and the quantity of colouring matter thus carried to them; or to the natural hue of the part being more or less calculated to show it, as in the eye, and white of the nails.]

This species is found most generally in the autumn. In many instances, it commences slowly and insidiously; there is felt a general restlessness, diminution of appetite, disturbed sleep at night, and disinclination for exertion of any kind: the urine is of a deep yellow, and deposits, perhaps, a pitchy sediment; the bowels grow sluggish, the dejections are clay-coloured or whitish, and have not the usual feculent smell. In some examples, however, the bowels are loose. The eyes and surface of the body look yellower than usual, and there is a very troublesome itching of the skin. In this species, however, there is little or no pain in the right hypochondrium, and little or no sickness at the stomach, though a frequent sense of nausea.

[In all cases of jaundice, except such as are very suddenly produced by the bites of venomous animals, and other particular causes, the yellowness commonly first shows itself about the inner angles of the eyes, the white of which is tarnished in a very early stage; but the whole cornea soon becomes manifestly yellow. On the temples, light yellow patches are next seen, which daily assume a deeper and deeper tinge. Similar yellow discolorations then appear on the face, neck, and breast, and all at length spread and unite, so as to cause a universal tinge. Yellow semicircles at the roots of the nails make their appearance very early. It is a curious circumstance, however, in the history of jaundice, that the yellow die of the skin should generally first show itself on the upper parts of the body, which are likewise the first to resume their natural colour.

* The actual presence of bile in the blood of jaundiced persons is denied by M. Deyeux (*Considérations Chimiques et Médicales sur le Sang des Ictériques*, 4to., Paris, 1809); and doubted even by M. Thénard. On the contrary, the researches of M. Clarion (*Journ. de Méd.* an 13), Orfila (*Elém. de Chim. Méd.*), Saunders, Alibert (*Nosol. Naturelle*, 1817), and others, tend to prove the correctness of the belief, as ancient as Hippocrates, that the bile passes into the circulation. John Hunter supposed that the mixture of bile with the blood would make it coagulate; but it is known that a quantity sufficient to give a yellow tinge to the serum, does not have the effect in question. We know that the serous secretions assume a remarkable yellowness. If a person labouring under jaundice is blistered, the fluid from the blister is yellow, and the serous fluids within the body are of the same colour. Dr. Cheyne related to Dr. Marsh the case of a lady, affected with jaundice, whose linen was rendered quite yellow by the exhalation from her skin.—*Ed.*

* See Saunders on the Structure, Economy, and Diseases of the Liver; Powell's Obs. on the Bile, p. 56; Bateman in Rees's Cyclopædia, art. JAUNDICE. Where the presence of the yellow matter of the bile in most of the solids and fluids constitutes this disease, we are not to imagine that an impediment to the transmission of bile through the biliary ducts into the duodenum always exists. In numerous persons, who died of or with jaundice, those ducts have been found perfectly free.—Andral, *Anat. Pathol.*, tom. ii., p. 616, and *Chimique Médicale*.

The tongue, palate, and teeth, have a yellow coating, which cannot be washed away. Whatever the patient puts into his mouth frequently has a bitter taste; and, indeed, the bitterness in the mouth is very annoying, even not at mealtimes. A partiality to acids and sourish food is also generally experienced.

In this affection, the pulse is ordinarily feeble. In the beginning, however, particularly if there be any pain in the hypochondrium, it is hard, and even frequent and full. But after the pain subsides, the pulse has been known to sink to only thirty strokes in a minute, some examples of which are reported by M. Andrée.—(See *Diet. des Sci. Med.*, tom. xiii., p. 403.)

In an early stage of the disease, free vomiting is of essential service. During this action, the diaphragm and abdominal muscles contract concurrently; and the whole of the viscera of the abdomen is forcibly pressed upon. Such a pressure must necessarily, therefore, affect the gall-bladder and biliary ducts, and oblige them to pour out their contents very freely; nor is there a more powerful means in our possession of unloading the liver of any viscous or stagnant fluid, or of restoring and invigorating its circulation. For this purpose, the antimonial emetics are preferable to those of ipecacuanha. They are less readily rejected, and excite a stronger stimulus from the first; and hence the vomitings they produce will continue for a longer period of time. To these should succeed a brisk purgative or two, with a copious use of diluting, sub-acid drinks, which, in ordinary cases, will easily remove every symptom. But if the disorder, from the obscurity of its march, be not soon suspected, the impeded passages will become more obstinately obstructed, the gall-bladder and bile-ducts will be distended; there will be a general feeling of fulness in the right side, with great irritation and fever; which last will often continue for a week or a fortnight after the obstructing cause has been removed.

Where the substance of the liver has been free, and the ducts alone obstructed, the quantity of bile that has accumulated in the gall-bladder has sometimes been enormous. In one instance, which terminated fatally, this reservoir was found, after death, to be so considerably dilated, as to be loaded with not less than two Scotch pints, or eight pounds, of this fluid.—(*Edin. Medical Essays*, vol. ii., art. xxx.) [Whether this case ought to be received as a confirmation of the statements of Galen, Darwin, and Powell, that jaundice is sometimes the result of paralysis of the gall-bladder, from immoderate distention of it, is a question not easily solved.] There is often a paresis or hebetude of action in the bile-ducts themselves; and where we have reason to suspect this, it will be most effectually relieved by the blue-pill, or small doses of calomel, or Plummer's pill, which is better than either, continued for two or three weeks at a time.* If the liver partake of this torpitude,

and no acute symptoms occur, the disease is apt to run into the fourth species, and must be treated accordingly.

SPECIES II. ICTERUS CHOLOLITHICUS. GALL-STONE JAUNDICE.

THE COURSE OF BILE OBSTRUCTED BY BILIOUS CONCRETIONS IN THE DUCTS, WHICH ARE AT LENGTH PROTRUDED AND DISCHARGED WITH THE FECES; FREQUENT RETCHING; ACUTE PAIN IN THE HYPOGASTRIC REGION, INCREASED UPON EATING.

This species is the *icterus calculosus* of most of the nosologists. It is so closely connected with the genus CHOLOLITHUS, or GALL-STONE, forming the third in the present order, in its general origin, symptoms, and mode of treatment, that the reader may be referred for almost all these to the latter. Yet it is necessary to give the two affections distinct places: for the yellow die of the skin and urine, which forms a pathognomonic symptom in icterus, occurs often, as we have already seen, without chololithus, even in its passing species and acute state, and very generally in its quiescent state. The liver itself is, in many cases, sound (*Heberden, Med. Trans.*, vol. ii., p. 124); but it is often connected with a morbid condition of this organ, and proceeds, perhaps, in some instances, from a morbid secretion of bile, by which it becomes more disposed to crystallize. Dissection has shown, that the seat of obstruction is most frequently in the cystic duct; next in the ductus choledochus; and then in the hepatic.* The rest will be explained under the genus CHOLOLITHUS.

whether any inflammation exist; whether the case is one of hepatitis; and, if it be, then it is to be treated on principles applicable to the latter disease. He coincides with many other practitioners in considering mercurial purgatives more efficacious in jaundice than any others.—(See *Med. Gaz.* for 1832-3, p. 489.) When jaundice appears to be connected with any affection of the liver of an inflammatory character, Dr. Abercrombie, after subduing the activity of the symptoms by local and general bleeding, blistering, low regimen, and free and continued purging, recommends mercurial friction, and friction with iodine.—*Pathol. and Pract. Researches on the Diseases of the Stomach, &c.*, p. 399.—Ed.

* Jaundice takes place from the presence of a gall-stone in the biliary ducts, when the calculus is a considerable time in passing, so as to produce an obstruction of some continuance in the duct: when it passes in a shorter time, though the symptoms may be equally severe, no jaundice follows.—(See Abercrombie on Diseases of the Stomach, the Intestinal Canal, the Liver, &c., p. 394, ed. 2.) "It has been disputed," says this able physician, "whether biliary calculi are ever formed in the substance of the liver, or in the gall-bladder only. But Morgagni mentions several instances in which they were found in the liver, and even of great size; and, therefore, there is no doubt of another point, which has been disputed, namely, that they may produce jaundice by sticking in the hepatic duct."—*Op. cit.*, p. 396.—Ed.

* In the treatment of jaundice, Dr. Elliotson very judiciously recommends us first to consider

SPECIES III.
ICTERUS SPASMODICUS.
SPASMODIC JAUNDICE.

THE COURSE OF THE BILE OBSTRUCTED BY A SPASMODIC CONSTRICTION IN THE COURSE OF THE BILE-DUCTS; THE DISEASE COMMONLY PRECEDED BY ACRIMONIOUS INGESTA, HYSTERIA, OR SOME VIOLENT PASSION OF THE MIND; AND SPONTANEOUSLY SUBSIDING WITHIN A FEW DAYS AFTER THESE ARE REMOVED.

The general symptoms of this affection are those of the preceding species, or of *chololithus means*, which so closely agree with the preceding; but the causes and mode of treatment are different; and it is necessary to attend to their specific signs, in order that they may be distinguished.

Spasmodic jaundice occurs for the most part in those of irritable habits, or whose liver, from a long residence in hot climates, from an undue indulgence in spirituous potations, or high-seasoned dishes, or from any other cause, is in a state of chronic irritability. So far as I have observed, it occurs more frequently in women than in men, probably from their passing a more sedentary life, and chiefly after menstruation has ceased, and the general form assumes a more corpulent shape.

There is also very commonly, in those who are subject to it, a sallowness of the skin, indicative of irritability and increased action of the liver, and of a larger regurgitation of bile into the bloodvessels than is necessary for the purpose of health. Dr. Heberden has observed that the liver is sometimes perfectly sound; and there is no doubt that this is a fact; for the irritability may originate in, and be confined to, the ducts; but it more generally commences in the liver itself, and is hence extended to the ducts, which, from their structure, are far more irritable, as well as more sensible, than the parenchyma, or general substance of the liver, and consequently far more susceptible of pain and spasmodic contraction.

[Spasm of the common duct is particularly mentioned by Dr. Cullen among the causes of jaundice, and Dr. Powell deems the fact well established, although it has often been denied. Andral enumerates four principal causes of the complete or incomplete, temporary or permanent, obstruction of the biliary passages, viz., the lodgment of a foreign body in them; their compression by membranous adhesions, or some kind of tumour; their spasmodic contraction; and the thickening of their mucous membrane from inflammation.—(*Arch. Gén. de Méd.*, tom. vi., p. 16.) Jourdan and Breschet, however, express their suspicions, that the latter state also prevails in every instance reported to be spasmodic.—(*Meckel's Anatomy*, vol. iii., p. 313, note.) Jaundice frequently accompanies spasmodic diseases. Thus it is said by Sydenham to come on during hysterics, a circumstance which the editor has never seen, and which is denied by Dr. Heberden. According to Dr. Saunders (p. 235), anger not only augments the quantity of bile, but likewise vitiates

it. Hence, flowing into the duodenum in large quantities, and regurgitating into the stomach, it produces the same effects as an emetic; and hence, probably, the term *choleric*, as applied to passionate people. If the ductus communis does not transmit it as fast as it is secreted, and the gall-bladder be already full, then it will return towards the liver, and, by entering the bloodvessels, produce jaundice. Dr. Bateman regarded this as the most probable explanation of the influence of the passions in producing a temporary jaundice, and of course he did not put much faith in the doctrine of spasm.* Among the less common causes of jaundice, a thickening of the biliary ducts is mentioned by Morgagni, who records a case of a total obliteration of the common duct.—(*Op. cit.*, Epist. 37, art. 10.)]

The primary cause of this disease we cannot always trace; but it is easily reproduced in those who are subject to it, by flatulent, acrimonious, or indigestible food, or by violent mental emotion. It is often also reproduced, or even primarily excited, by cold in the feet, drinking cold water when the body is greatly heated, and a transfer of atonic gout from the extremities to the stomach, or any part of the intestinal canal. We have hence a clear proof of the strong sympathetic connexion which exists between the liver and various parts of the body. [The jaundice sometimes produced by corporeal suffering, irritation in the alimentary canal, and the bites of venomous animals, is referred by Hoffmann, Mead, and Bosquillon, to the spasmodic species.] An affection of the brain will also often produce jaundice (*Marsh, in Dublin Reports*, vol. iii.); and hence a frequent exciting cause is a sudden and violent burst of the depressing passions, as terror, jealousy, and despondency. It is, indeed, most probable, that the torpidity induced directly in the organ of the liver, from the exhausting heat of tropical climates, is also greatly augmented by the operation of the same cause on the skin, and the sympathy of the liver with this organ.

The disease is ushered in by a sense of fullness at the stomach, accompanied with great languor and nausea; a violent pain at the pit of the stomach soon succeeds, with an almost incessant sickness, and an utter inability of retaining either food or medicine of any kind. The pain grows intolerable, and shoots towards the left shoulder, or spreads round the loins,

* Rees's Cyclopædia, art. JAUNDICE. Dr. Abercrombie doubts the truth of the doctrine of spasm of the biliary ducts as a cause of icterus (on Dis. of the Stomach, pp. 394 and 400); and Dr. Burder is of opinion that we have no evidence of its existence.—(*Cyclop. of Pract. Med.*, art. JAUNDICE, note, p. 5.) The two following cases are quoted by Dr. Abercrombie, as proving clearly the origin of jaundice from passions of the mind: a woman, mentioned by Hoffman, was affected with jaundice every time that her mind was agitated; and a medical gentleman, spoken of by Mr. Cooke (on Derangements of the Digestive Organs), became jaundiced almost invariably when he had a dangerous case under his care.—Ed.

and girds them as with a cord. The epigastric region is greatly distended, and cannot endure the pressure of the hand; while the pulse exhibits little variation.

The bowels are for the most part costive, and moved with difficulty. [The stools are scanty, of a grayish, or clay colour, and, as long as the urine is of a deep yellow or saffron colour, voided with difficulty. But, when this secretion becomes paler, they assume their natural yellowness again, are more copious, and the patient begins once more to be conscious of the sensation preceding or accompanying their natural expulsion; a sensation, that is lost while the bile continues to tinge the urine in a considerable degree. It should be understood, however, that costiveness does not always precede or attend the first symptoms of jaundice; but as Monro, Pringle, and Powell attest, there is sometimes a considerable looseness, with grayish stools of a faint, or rather sour smell. At first the urine is yellow and quite limpid; but it afterward becomes frothy, saffron-coloured, reddish, and very thick; sometimes almost black, depositing a sediment like brick-dust, or dark blood. In proportion as the yellowness of the skin fades, the urine loses its saffron colour, and becomes clear again.] This colour shows itself the sooner in proportion to the violence of the other symptoms, and especially of the retching; and the surface of the body, and especially the fine sclerotic coat of the eye, assume the same livery. And if the disease become chronic, the yellow die is not confined to the skin, or even to the fluids, but pervades every part of the body, the most compact as well as the most porous; so that the pericardium, the heart, the peritoneum, the meninges, the substance of the brain, the cartilages, and even the bones, are clothed with the common colour. Stoll (*Rat. Med.*, part iii., p. 386, *et passim*), Lieutaud (*Hist. Anat.*, p. 190), Bartholin (*Epist.* iii., p. 419), and Morgagni (*Op. cit.*, epist. xxxvii., art. 7), give various examples of this; though the last observes, that a yellow tinge of the brain is a rare occurrence.

One of the latest fluids that becomes tintured is the milk in icteric wet-nurses; probably in consequence of its rapid passage and elaboration from the fluids introduced into the stomach. Dr. Heberden has remarked, that, in wet-nurses, the milk is never tainted with the bile either in taste or colour; but this assertion is too general, and at variance with the observations of other pathologists. Reidlin lays down the fact more correctly, in affirming that all the humours are *sometimes* coloured yellow.* And hence, indeed, the only reason we can assign for the bilious and bitter taste that is often present in the stomach, inasmuch that every thing the

patient eats or drinks partakes of this quality: while the common bile-duct is locked firm, the intestines are without bile, and the stools are whitish or clay-coloured. The fact is, that the whole mass of blood is so impregnated with bile, that the saliva, and all the other lubricating secretions of the mouth, fauces, and œsophagus, and probably the gastric and pancreatic juices, are loaded with the same material, so that the sense of taste cannot be otherwise than affected.

The jaundiced have, from a very early period, been said to see all objects of a yellow hue, as they appear to us when looking through a yellow object-glass; from which we may judge, that the humours of the eye, like the other fluids of the body, are also tinged, as Celsus observes (*Medicin.*, lib. iii., sect. xxiv.), with the resorbed bile, and communicate the tinge to the picture thrown upon the retina. Lucretius, so far as I know, is the earliest writer, of those that have descended to our own day, who has made this remark, which he introduces (*De Rer. Nat.*, iv., 333) as illustrative of another subject, and appeals to as a familiar fact:—

“*Lurida præterea fiunt, quæquomque teneantur
Arqueatæ; quia luroris de corpore eorum
Semina multa fluunt, simulacris obvia rerum;
Multaque sunt oculis in eorum denique mixta,
Quæ contage sua palloribus omnia pingunt.*”

“The jaundiced, thus, see all things round them in yellow; every object as it flows [clad Meeting new tides of yellow, from their forms Thrown forth incessant; and the lurid eye, Deep, too, imbued with its contagious hue, Painting each image that its orb assails.”

Dr. Heberden, however, affirms, that all the jaundiced patients he has at any time attended have contradicted this opinion, with the exception of two females, whose testimony he is disposed to hold lightly; and Professor Frank is decidedly of opinion, that no such affection takes place. Yet from a single case in my own person, produced, when a student, by long-continued pressure of the epigastrium against the edge of a table in copying my shorthand minutes of medical lectures, I can confirm the general opinion: for, the first suspicion I entertained of my being affected with jaundice, was from the yellow tinge with which every object around me appeared to be arrayed. To produce this effect, however, it is necessary, as already observed, that the crystalline lens, and, perhaps, all the humours of the eye, should be tinged, and acquire the yellow hue of the sclerotic coat. This certainly does not at all times take place; and where the humours are unaffected, objects must certainly be seen in their proper colours; but where they are thus tintured, and form a yellow transparent medium, it seems difficult to conceive how a picture, transmitted through them, can avoid catching their own die; and hence we may see why some persons, labouring under the jaundice, perceive objects coloured with yellow, and others in their proper hues.

[The statement here made by the author, and which agrees with what Morgagni has said

* *Lin. Med.*, 1697, Febr., Obs. 7. In examining the body of a woman who died in the Lock Hospital of Dublin, from protracted disease, connected with jaundice, Dr. Morris found the mammae full; and, by moderate pressure, several ounces of a yellow tenacious fluid, having all the visible properties of pure bile, were discharged from them.

—Ed.

relative to this curious point,* seems to be confirmed. Dr. James noticed this disorder of vision in two old patients affected with jaundice. Hoffmann records two similar cases; and Alibert met with an additional example in a girl who was in the Hôpital St. Louis. Dr. Pemberton met with two instances, and in both the jaundice was not very intense. Dr. Elliotson has also had patients similarly affected; and he remarked that, in these examples, there was either a fulness of the vessels round the cornea, or a degree of inflammation of the conjuncture present.—(*Med. Gaz.* for 1832-3, p. 487.) The rarity of this affection of vision in jaundice corresponds to, and depends upon, the rarity of the extension of the yellowness to the humours of the eye.]

I have said that this species of jaundice, and the remark may be applied to all the species except the last, sometimes assumes a chronic form. In this case the distressing symptoms of severe spasmodic pains, intumescence, and sickness subside; but the bile does not flow freely into its proper channel, and continues in a greater or less degree to be absorbed and carried into the circulation. The cause of this seems to be an insensibility and paresis approaching almost to a paralysis in the biliary tubes, and a chronic irritability in the hepatic absorbents. Under these circumstances, moreover, the bile that thus tardily finds its way into the duodenum must be grosser and more viscous than in a healthy state; and hence another cause of retardation and irregular supply. There is also a change in the colour, as well as in the consistency, of the bile, frequently to be met with in the chronic state of the disease; which may sometimes be the result of a morbid secretion, but is perhaps more generally that of a chymical decomposition, from the joint influence of decay and animal heat. And under these circumstances, the bile has at different times and in different persons been found acid, acrid, saltish, insipid, whitish, black, green, eruginous, and versicoloured. It has been found as dense and dark as elder-rob (*Eph. Nat. Cur.*, dec. iii., ann. iv., obs. 86); as tenacious and limpid as the white of eggs (*Stoerck, Ann. Med.*, i., 124); and as crowded and granular as the spawn of frogs.—(*Eph. Nat. Cur.*, dec. ii., ann. ix., obs. 9.)

In this chronic form, jaundice has sometimes run on for a long period of time, occasionally for a twelvemonth. It has alternated itself with intermittents; proved a salutary crisis to fevers; or has itself been carried off by exanthems of the more violent kind; and especially by miliary and scarlet fever. The general functions, when it has assumed this form, and the constitution has become habituated to it, are sometimes so little disturbed, that we see people of the middling and lower ranks of life who

cannot afford to keep at home, and who would certainly be the worse for it if they could, going about the streets with the jaundice hue covering their hands and faces, and not prevented from engaging in any of the ordinary concerns of life in which no great degree of exertion is required.*

In the treatment of this species, emetics and cathartics, so highly beneficial in *icterus cholæus*, are of doubtful advantage. When, however, the bowels are particularly costive, or there is reason to suspect the lodgment of a small calculus, or of any inspissated bile in the biliary duct, purgatives are indicated in the first case; and both purgatives and emetics in the last. But in all other examples they must add to the disease by increasing the irritation, and should give way to bloodletting, if the patient be in vigorous health, succeeded by opiates, the warm-bath, or warm and anodyne fomentations applied to the epigastrium.† The opiate should be given in pills, for the stomach will often reject liquids of every kind. Two or three grains of the extract of opium may be tried at first, and if this be insufficient, the same or even a larger dose should be repeated half an hour afterwards, and continued till the pain abates. Blistering the seat of pain has been advised by many; and I have often tried it, but without any decided effect. If useful at all, it is rather in preventing a return of the paroxysm, than in shortening or mitigating it when present; and will hence be most advantageously resorted to in the interval.

The ointment of tartarized antimony, so warmly recommended by Dr. Jenner, has a much fairer chance of success; and, in the author's practice, has at times effected a cure where other means had been found useless. A portion of the ointment, equal in size to a hazelnut, should be rubbed every night into the epigastric region till the ordinary eruption appears.

The general soreness upon pressure, and the excitement of the hepatic absorbents, as already observed, continue very frequently for several weeks after the spasm itself has subsided; and

* All men of experience will agree with Dr. Abercrombie on this part of the subject, namely, that long-continued jaundice generally depends either upon chronic disease of the liver, or upon other diseases of neighbouring organs, compressing the biliary duct. Yet, as this judicious and correct observer has remarked, chronic disease of the liver of most extraordinary extent is sometimes unattended with jaundice.—See Abercrombie on Diseases of the Stomach, &c., p. 401.—Ed.

† When jaundice is characterized more by spasmodic pain than inflammation, Dr. Elliotson deems the hot-bath and opium the best means of relief. But if the pulse be quick and strong, he recommends bleeding, as the most effectual antispasmodic that can be employed. He prefers also combining the opium with a full dose of calomel, which will prevent costiveness, and produce a free discharge from the alimentary canal. A poultice over the part, he says, is very useful.—(Lect. at London University, pub. in *Med. Gaz.* for 1832-3, p. 489.) Dr. Good has this eminent physician with him as a believer in the reality of spasmodic icterus.—Ed.

* Aliquando tamen, sed rarissime, fieri potest, ut flava in hoc morbo objecta appareant, nimirum si cornea tunica bile tota saturata sit, neque tum solum, quod et Mercurialis concedit, verum etiam si quando oculorum humores summa flavedine infecti sunt.

consequently there will be great languor, indisposition to labour, and a tawny skin.

For all this, a generous diet, cheerful company, and moderate exercise, and especially riding on horseback, go very far towards effecting a cure; and perhaps farther than any course of medicine whatever. The bowels, however, must be kept open with warm aperients, and the stomach and abdominal viscera invigorated by bitter tonics.

The dandelion (*leontodon taraxacum*, Linn.) has been highly extolled by many writers of established reputation in all obstructions of the liver, and, indeed, in obstructions generally; and has been used in its roots, stalks, and leaves. All these abound with a milky, bitterish juice, which was at first supposed to be saponaceous, and hence warmly commended as a resolvent by Boerhaave. Bergius, Murray, and Dr. Pemberton have since contributed to support this character, and they are consequently in daily use even in the present day.* The plant has no doubt, therefore, deobstruent virtues; but it has not fallen to my lot, though I have many times given it a fair trial, to add my suffrage in its favour. Its most obvious character is that of increasing the flow of urine.

Soap and alkalis, however, seem to have much better pretensions to favour; and have been still more widely employed in this disease, and pretty extensively regarded as general, and hence as hepatic solvents. Yet that they do not act as solvents in hepatic cases, is clear from a striking instance related by Dr. Heberden, who tells us that he once attended a person who, for a stone in the urinary bladder, had been in the habit of swallowing an ounce of soap every day for seven years. His body was opened after his death; and, notwithstanding such an extraordinary quantity of soap had been taken, a great number of stones were found in the gall-bladder, without the slightest marks of having been operated upon by any decomposing power.—(*Med. Trans.*, vol. ii., p. 65.)

Soap, however, and other alkaline preparations, may perhaps be useful in another respect: I mean, in becoming a substitute for the deficient bile, and cleansing the bowels by their possessing something of the same chymical properties. Yet too much stress must not be laid even upon this virtue; for large quantities of acids, as lemon-juice, have at times been taken with so much apparent benefit, as to gain, also, the credit of a cure. There is one drawback against whatever may be the remedial powers either of soap or of the alkalis; and that is, their frequent and easy decomposition in the stomach, in consequence of its containing at all times some quantity, and occasionally a very large proportion, of acidity. We may often, perhaps, introduce so much of these

medicines as shall be more than sufficient to neutralize the acid; but where a large quantity is wanted for this purpose, it is better to employ the alkali alone than combined with oil, as less troublesome to the stomach. And where this is done, the best, because the most manageable preparation of the alkalis, will be that which is the purest and most concentrated, as the liquor potassæ; nor does it appear that the other alkalis would answer better if we had forms for elaborating them in the same manner. The Cheltenham spring has unquestionably been serviceable in the relics or sequelæ of the disease, and where exercise and a tonic plan are decidedly indicated. But where we have reason to believe that the bile is secreted in a depraved condition, and particularly where the disease is connected with a morbid state of the liver, the Bath waters, used both internally and externally at the same time, will be found more beneficial than those of Cheltenham.

Another remedy to be spoken of, which of late years has excited great attention, is the diluted aqua regia bath, invented by the late Dr. Scott. For nearly thirty years he was in the habit of using this preparation, and had tried it in almost every variety of strength, and almost every variety of proportion, which the two acids that enter into the composition may be made to bear to each other. He commenced his experiments in India, where, on account of the greater degree of torpidity the liver is apt to acquire than in more temperate climates, he was in the habit of forming his bath stronger, and making it deeper than he found it proper to do in our own country; and where, nearly thirty years ago, he plunged the Duke of Wellington into one up to his chin, for a severe hepatic affection he was then labouring under, and thus restored him to health in a short time.

In England it was not often that he found it necessary to raise the bath much above the knees, and frequently contented himself with a mere foot-bath or common wash-hand basin alone. In both which cases, however, the attendants on the patient should sponge him at the same time with the diluted aqua regia, over the limbs, and occasionally over the body.

The aqua regia should be compounded of three parts in measure of muriatic acid and two of nitric acid; and in preparing them for use, a pint of the combined acid is to be mixed with the same measure of water. This constitutes the diluted acid, or diluted aqua regia. The acid bath is to consist of three ounces of this diluted acid to every gallon of water. It should, however, be observed, by those who are inclined to form this mixture extemporaneously at their own houses, that if either of the acids be poured immediately on the other, a large volume of very offensive gas will be disengaged; on which account, it will be better to pour them separately and slowly on their proper measure of water.

If the acids be of adequate strength, the mixture subdiluted for bathing will, to the taste, have the sourness of weak vinegar, and perhaps prick the skin slightly, and excite a peculiar rash, if very delicate, but rarely otherwise, after

* The reputation of the leontodon is sustained by the experience of some modern American physicians. The occasional use of the blue-pill, followed by mild aperients, with the alkalis and the infusion of dandelion, has been found efficacious in some long-continued cases of the nature described in the text —D.

it has been applied to the surface for half an hour. But since these acids vary much in their degree of concentration, as distilled by different chymists, there will be some variation in their power. The strength of the bath, however, should not be much greater at any time than the proportion here laid down; for otherwise it may excite a troublesome rash, and give a yellow hue to the nails and skin of the feet, or whatever other part is exposed to its action. A narrow tub for a knee-bath, just wide enough to hold the feet and reach the knees, should contain three gallons of the prepared bath liquor, and consequently about nine ounces in measure of the diluted aqua regia. For a foot-bath, half a gallon may be sufficient, and a common wash-hand basin may be employed as a vessel for the purpose. The feet should remain in the bath for twenty minutes or half an hour; and the legs, thighs, and abdomen be, in the mean time, frequently sponged with the same. In the winter the water may be used warm; but this is not necessary in the summer. The bath may be employed at first daily for a fortnight or three weeks, and afterward every other day, or only twice a week.

Dr. Scott affirms that he has employed this process with decided advantage in almost all cases dependant on a morbid secretion of bile; whether the secretion be superabundant, defective, or depraved. He finds it often, within a few hours of the first bathing, increase the flow of bile, and meliorate its character; and in consequence hereof, excite an expulsion of dark-coloured feces, bright-coloured bile, or bile of a brown, green, or black colour, like tar mixed with oil. He has told me also, that when employed in the midst of a paroxysm of severe pain from spasm of the biliary ducts, or the passing of a gall-stone, he has often known it operate like a charm, and produce almost immediate ease.—(See also *Med. Chir. Trans.*, vol. viii.)

From the rapidity, therefore, with which it acts in some cases, he is inclined to think that it operates, not by the absorbents, but by the nerves; and has made various experiments to show that it is the chlorine of the muriatic acid alone, by the present process decomposed and set at liberty, that produces the benefit of the bath. To prove this, he employed a bath of water saturated with chlorine, obtained from the muriatic acid by mixing it in a retort with the black oxyde of manganese; and the same salutary effects followed: and he has given this saturated solution in doses of half or three quarters of an ounce, three or four times a day, mixed with the same quantity of spearmint, or any other distilled water, with evident benefit, in very numerous hepatic cases of great obstinacy.

This account may be rather overcharged, from the ardent mind of its intelligent inventor: but the process is worth following up, and varying in other proportions, as well as employing in other families of diseases. My own use of it is at present too limited to speak with decision; yet, so far as I have tried it, it has certainly appeared to me to allay irritation and produce a tonic effect. In two or three in-

stances, the advantage has been decisive; and patients who had hitherto been seldom two months without a severe return of the complaint, have entirely escaped, and apparently lost the morbid predisposition. In a few other cases, it has completely failed.

Mr. Wallace has been employing chlorine in the form of gas, obtained by a mixture of muriatic acid with the black oxyde of manganese, as well as diluted with aqueous vapour; and he regards the peculiar eruption brought out by it as a favourable sign.*

SPECIES IV. ICTERUS HEPATICUS. HEPATIC JAUNDICE.

THE COURSE OF THE BILE OBSTRUCTED BY A DERANGEMENT OF THE LIVER FROM SCIRRHUS OR OTHER INDURATIONS; OCCASIONAL RETCHINGS AND DYSPEPSY: LITTLE OR NO PAIN IN THE RIGHT HYPOCHONDRUM.

In the preceding species, the appendages to the liver, as the gall-bladder or gall-ducts, are the chief seat of disease, at least in its commencement. In the species before us, the disease is chiefly seated in the liver itself. It may be a result of the preceding species when they have assumed a chronic form; but, as the liver itself is often affected from the first, it is entitled to be treated of as a distinct species. The course of the bile, indeed, is evidently obstructed, but rather in its secretion, or separation from the substance of the liver, than in its transmission by the biliary tubes.

This species is noticed by Boerhaave, by Sauvages, and by Dr. Cullen in his Synopsis, though he has offered no remarks on it in his First Lines. In Boerhaave, however, it imports altogether a different disease, for it is jaundice produced by hepatitis,† or inflammation of the liver; and is hence a mere symptom, to be removed alone by a removal of the idiopathic complaint.

It is more accurately described by Richter, who confirms and illustrates the opinion of Vogel and Selle; both of whom suppose it to depend upon some peculiar irritation in the liver itself, or in the whole hepatic system; but an irritation not dependant upon or directly leading to inflammation. This irritation is of various kinds, and produces different effects, all of which become causes of obstruction to a free flow of the bile into its proper channels. One of the most common effects which operate in this manner, is a scirrhous enlargement of the whole, or of some particular part, of the liver. Another is an accumulation of calculous concretions in its substance; of which Richter gives a striking and complicated example in a person, who, after death, was found to be without a gall-bladder, and whose liver was filled with whitish calculi of different forms and

* Researches respecting the Medical Powers of Chlorine, London, 1822.

† Van. Swiet. Comment., Hepatitis et Icterus multiplex, tom. iii., § 914.

sizes, from that of a pea to that of a cherry. In this case there can be no question that the bile, whose colouring matter was diffused over the entire body, was not only formed in, but immediately absorbed from, the penicilli, or pores of the liver, in consequence of obstruction, without being collected into a reservoir.

This is the worst state in which jaundice can possibly make its appearance; for, though there is little or no pain, it shows disease in the structure of the liver, and is frequently a mark of a broken-up constitution. It is in fact found rarely in the young and vigorous; but almost always in those who have drunk hard, or lived hard, and especially have been exposed to much labour in hot climates, or have suffered under repeated attacks of quartans or other chronic intermittents.

The art of medicine can here do but little; and we have too often to witness the picture, drawn so feelingly of the Athenians during the plague:—

“— Defessa jacebant

Corpora; mussabattacito *MEDICINA timore*.”*

It is only in an early stage of this disease, if happily we should be so soon consulted, that mercury has any chance of being successful; and it should be given rather as an alterant in small doses pertinaciously followed up, than in large proportions so as to excite a pyalism; for we have here no strength to draw upon without injury. “I think,” says Dr. Baillie, “that many practitioners of the present day have erred in administering mercury too long, and in too liberal doses. When mercury is carried beyond the point that is necessary, it often injures the constitution by weakening it, and rendering the nervous system very irritable.” In some cases, small doses of calomel in combination with opium have been serviceable; and I have certainly found benefit from covering the hypochondriac region with a large plaster of the emplastrum hydrargyri cum ammoniaco. For the rest the patient must be put upon a general tonic plan: his diet should be generous without being highly stimulant; he should use such kind of exercise and in such proportion as best agrees with him; and the chalybeate springs, corrected as those of Cheltenham by neutral salts, form the best mineral invigorant to which he can have recourse. Possibly, in this malady also, the diluted aqua regia bath may be of service, employed as recommended under the last species.†

[In that state of the liver which produces

* *Lucr. De Rer. Nat.*, vi., 1176.

† The Ballston and Saratoga mineral waters of the state of New-York have long been celebrated for their medical qualities, in several of the forms of jaundice or biliary obstruction, provided that general irritation and local inflammation be first judiciously remedied. Dr. Francis states that the sulphurous waters of the Avon spring, in Livingston county, New-York, are extremely useful in like cases, particularly where the tone of the digestive organs is impaired.—See his *Observations on the Mineral Waters of Avon*, in the *United States Med. and Surg. Journal*, No. 1, New-York, 1834. The waters of the yellow and white sulphur

jaundice towards the end of intermittent fevers, mercury is the best and only remedy; and calomel, in small doses, is the form under which it is the most efficient. When jaundice arises from congestion of the vessels of the liver, general bloodletting, or (if the patient's reduced state prohibit it) local bleeding, by the application of leeches, or cupping-glasses, to the right hypochondrium, will be proper; afterward, mercurial and iodine frictions are indicated.]

SPECIES V.

ICTERUS INFANTUM.

YELLOW GUM. JAUNDICE OF INFANTS.

THE COURSE OF THE BILE OBSTRUCTED BY VISCID MECONIUM; WITHOUT PAIN OR DYSPEPSY; EASILY REMOVED BY PURGATIVES.

This is the mildest form under which jaundice makes its appearance, and that which is carried off with least trouble. In ordinary cases, the only symptoms are the pathognomonic colour, and a degree of languor and drowsiness beyond what is common to infants on birth or shortly after.

A yellow hue, however, on the surface of infants, is not necessarily a symptom of jaundice, properly so called; for Lentin,* Cullen, and many others have well observed, that such a discoloration may also be the result of a peculiar yellowness of the serum of the blood, unconnected with bile (*Müller Origine Icteri*, Jen., 1783); analogous to the golden teint which we so frequently find diffusing itself over the surface of a contusion, when the finer and more limpid parts of the effused fluid have been carried off, and the colouring matter of the serum that still remains behind is hereby become more concentrated: as we shall have to notice more at large when treating of this affection under the name of *Aurio*, constituting the fifth species of the genus *EPICHRISIS*.†

A dose of castor-oil, or any other active

springs of Virginia are highly beneficial to invalids suffering from disorders of the digestive organs, chronic affections of the liver, the sequelæ of protracted intermittent fever, &c., and particularly in cases where mercury has been prescribed to excess for disorders of this character.—See *Bell on Baths and Mineral Waters*, pp. 436, 7.—D.

* See Baume's Description de l'Ictère des nouveaux nés, &c., Nîmes, 1788. Cull. Synops. Nosol., Gen. xci., 5, note.

† *Cl. vi.*, *Ord. iii.*, Gen. x. This view coincides with that taken by Andral: sometimes, he says, the icteric teint of the skin seems to be merely the result of an effusion of blood in its texture. Such appears especially to be the nature of the icterus of newborn infants, in whom the red hue of the skin may be seen gradually to change into a yellow teint, which, in its turn, is effaced, and replaced by the natural complexion. In the livers of such children, no constant lesion has been noticed that would account for the jaundice. This organ is said to have been sometimes seen gorged with blood; but it is quite as frequently found in this state, yet uncombined with icterus.—See Andral *Anat. Pathol.*, tom. ii., p. 616.

purgative, will generally be sufficient to remove the obstruction, which in almost every instance proceeds from meconium more than ordinarily tenacious, and consequently will carry off the disease. But frequently the mouth of the ductus choledochus communis is so completely infarcted with this viscid matter, that purgatives are insufficient; and, in this case, an emetic should be given, and in a few days repeated, if necessary.

[Icterus being seldom a disease essentially mortal, and only having, in general, a fatal termination when combined with some serious organic disease, a distinction should be made between persons dying with jaundice, and those dying from it; a distinction first made by the celebrated M. Portal.

The bodies of ictical subjects usually present the same morbid colour which they exhibited in life. However, according to M. Portal, the intensity of the colour is sometimes diminished; while some bodies, which never showed any marks of jaundice previously to death, afterward turn of a very deep yellow. A tendency to anasarca is generally noticed, and, when incisions are made in the cellular membrane, a good deal of serum, which is of a more or less yellow hue, flows out. Whatever fluid is found in the ventricles of the brain, or in the chest, or abdomen, is likewise either of that colour, or reddish. In short, every texture, and even the most compact parts, present a yellow tinge; as the fat, the muscles (which with other organs are softened), the membranes, especially the serous ones; the lining of the arterial system; the tendons; the cartilages; the periosteum; and the very bones.

According to Morgagni, the lungs, heart, liver, spleen, and kidneys are softened, their texture containing a limpid yellow or reddish fluid. Most of the secretions partake of the same tinge.

No part, however, is more frequently affected in jaundiced subjects than the liver. Sometimes dissection demonstrates it to be either in a state of chronic inflammation,* or of preternatural volume or smallness, or converted into a fatty matter resembling tallow. Abscesses, ulceration, biliary concretions within its substance, and numerous close adhesions of it to the neighbouring parts, are likewise occasionally discovered after death.†

The state in which the gall-bladder is found

* In jaundice, an inflammatory condition of the liver, in an obscure form, and often of small extent, may be suspected, when the disease is attended with pain, or tenderness in the region of the liver, though without fever, or any symptoms of active inflammation. The cases of more decided inflammation of the liver are alleged by Dr. Abercrombie to be attended with jaundice only when the inflammation is seated chiefly on or near its concave surface.—On Diseases of the Stomach, &c., p. 397.

† Dr. Stokes (*London Med. and Surg. Journal*, March, 1834) has seen an instance of jaundice arising from an aneurism of the hepatic artery, and also mentions the accumulation of fecal mat-

ter is extremely diversified; very often it contains calculi, of which there may be only one or many. The single one is occasionally very large; the numerous ones, sometimes amounting to hundreds, are usually of diminutive size.* At the same time, the gall-bladder may contain no bile, or be prodigiously distended with it. Van Swieten speaks of a case, in which the gall-bladder reached from the liver to the crista of the ileum, and had more than a pint of bile in it. In some cases this fluid has been found viscid, almost black, and to contain gritty particles like sand. Dr. Bostock (*Bright's Reports*, 4to., Lond., 1827) has given the analysis of the fluid of the gall-bladder in a case of protracted jaundice, accompanying tubercular liver and dropsy. It had an orange colour and thin consistence; the animal matter in it was almost entirely albumen, with a little colouring matter different from that of the bile; and, in fact, it contained none of the usual biliary principles. In particular examples, the gall-bladder exhibits traces of the effects of inflammation, its coats being thickened and indurated. In one instance Bonnet (*De Ictero*, obs. 13) found excrescences within its cavity. Sometimes the gall-bladder is adherent to the neighbouring organs. In one patient who died with jaundice, the gall-bladder and cystic duct were altogether wanting.—(*Bourgeoise, De l'Ictère*, 4to., Paris, 1814.)

At various points of their course, the hepatic, cystic, and common biliary ducts frequently contain calculi of different sizes. When these concretions lodge either in the hepatic or common duct, they completely block it up; and hence it is often found considerably dilated above the obstruction, and containing a large quantity of bile; a circumstance that does not occur when the foreign body lodges in the cystic duct. Sometimes these several canals are so contracted, that a small probe cannot be introduced into them. Stoll met with the common duct in what he calls a cartilaginous state. Cabrolus has recorded a case of jaundice, in which there was a malformation of the common duct, its end towards the liver being very wide, and its communication with the bowels as minute as the extremity of a capillary vessel. The biliary ducts are often found compressed, and even more or less obliterated by various kinds of tumours formed in their vicinity. A most remarkable enlargement of the biliary ducts, in consequence of the pressure of a scirrhus pancreas on the common duct, is recorded by Mr Todd. After death, more than a quart of bile was found in them. The patient's face is represented to have been quite of an orange colour.

ter in the intestines as another cause of this complaint.—D.

* Calculi in the biliary ducts are not unfrequent causes of jaundice. "Their mere presence in the gall-bladder does not usually seem to produce either local or general inconvenience. Out of nineteen instances of biliary calculi, which occurred to Morgagni, besides four to Valsalva, in post-mortem examinations, not one had experienced jaundice."—Dr. Burder in Cyclop. of Pract. Med. Also Andral, *Précis d'Anat. Pathol.*, tom. ii., p. 614.

—(*Dublin Hospital Reports*, vol. i., p. 325.) Dr. Eliottson states, that jaundice has arisen from the lodgment of a lunbricus in the duct of the liver (*Med. Gaz.* for 1832-3, p. 488); and, if this be the case, the opinion entertained by Andral and Cruveilhier, that worms only pass into this situation after the patient's decease, would appear to be incorrect.

When the common duct is rendered completely impervious by the lodgment of a calculus, and yet no jaundice takes place (a fact that has sometimes been noticed), the possibility of the existence of a second biliary duct has been suggested as an explanation of the circumstance. This preternatural arrangement is even admitted as possible, both by Morgagni and Portal, whose statements rest upon several cases in which it had been traced.

In some individuals who had been free drinkers, and died with jaundice, Stoll found the pylorus contracted, and a considerable portion of the stomach hard and almost cartilaginous.—(*Ratio Medendi*, pars tert.)

Sometimes the duodenum around the termination of the common duct has been found scirrhus and ulcerated. Dr. Marsh has related several instances, proving that jaundice may arise from an inflammatory state of the mucous membrane of the duodenum, whereby the mouth of the common duct was obstructed.—(*Dublin Hospital Reports*, vol. iii.)

Dissections prove that the compression of the biliary passages may be the result of disease and enlargement of the pancreas or spleen. A case of black jaundice is recorded by Zacutus Lusitanus, as having taken place in a person in whom the spleen was entirely wanting.

Sometimes the vena portæ has been observed to be very considerably enlarged, not merely in its trunk, but its ramifications. Any cause producing an obstruction of the circulation in this vessel may give rise to a species of jaundice very difficult of cure. In one subject which was opened by M. Honoré, the vena portæ was almost impervious in consequence of a tumour formed in its parietes. The patient had been afflicted with jaundice, and the stomach was cancerous.—(*Archiv. Gén. de Méd.*, Septembre, 1823.)

Among other causes of jaundice, dissection, as well as clinical experience proves, that collections of fluid in the abdomen, and abscesses of the liver, deserve to be particularly mentioned. In a woman whom the editor opened some time ago at the request of Dr. Pinckard, and whose gall-bladder had been nearly annihilated, there were abscesses occupying at least two thirds of the interior of the liver.

Jaundice is not an uncommon attendant also on organic diseases of the heart and lungs. When connected with those of the heart, it probably arises from the impeded return of the blood from the liver.—(*Abercrombie's Path. and Pract. Researches on Diseases of the Stomach*, &c., p. 399, ed. 2.)

Though the above account corresponds to what is commonly established by dissection, it is curious that sometimes all the foregoing mor-

bid changes exist unaccompanied by the slightest degree of jaundice. And sometimes jaundice prevails in subjects in whom no organic disease whatever can be traced after death. Here Hoffmann and Morgagni have recourse to the suspicion of spasm of the biliary ducts, which are supposed to become relaxed after death.]

GENUS II.

MELÆNA.

MELENA.

THE COLOUR OF THE EYES AND SKIN YELLOW-GREEN, FULGINOUS, LEADEN, OR LIVID; THE DEJECTIONS DARK-COLOURED, GRUMOUS, PITCHY, OR CONSISTING OF BLOOD; BILE AND THE INTESTINAL SECRETIONS MORE OR LESS ALTERED; ANXIETY; DEPRESSION OF SPIRITS.*

This is the Melæna, or *Μελaina νόσος* of the Greeks: a name given to it by Hippocrates, who has been followed up by the Latin writers; among whom, with a mere translation of the term, it is called MORBUS NIGER, or the *Black-disease*, whence the name of BLACK-JAUNDICE.

The colour of the skin under this disease is always dark, but differs considerably in its shades, and even in its hue, in different individuals.—(*Lib. xiii.*, obs. 23.) It sometimes approaches to a green; whence by Forestus, Razouz (*Tables Nosol.*, p. 129), and other writers, it has been called icteritia, or icterus *viridis*; on which account, it has of late been described under the name of *Green-Jaundice* by Dr. Baillie.

This versatility of colour is not to be wondered at; for I have already had occasion to observe, that the bile, under different states of a diseased liver or its appendages, exhibits very different appearances. In respect to consistency, it has sometimes been found watery (*Biachi. Hist. Hep.*, p. 129; *Sebez. Exercit. Méd.*, p. 93), viscid, or flaky; in respect to colour, green (*Augen. Hor.*, tom. i., lib. xi., ap. 5), muddy, pale-white (*Eph. Nat. Cur.*, dec. i., ann. iv., obs. 194; *Cent. iii.*, ix., app. 9), pitchy-black, eruginous (*Stoll, Rat. Med.*, part i., p. 292), and versicoloured; in respect to internal properties, insipid, salt, acid, or acrid and effervescent. In the disease before us it is always of a dark, and often of a black or pitchy hue. The stools are dark-coloured, and occasionally almost black; but the urine is sometimes pale, and generally clear.

Dr. Cullen seems to have been doubtful how to dispose of the genus MELÆNA. In his Synopsis, he has omitted it altogether: in his First Lines he has briefly noticed it, first under hæmatemesis, and again under diarrhœa, as though melæna were a variety of both these. But not satisfied with this distribution, he afterward introduced it into his "Catalogue of Diseases omitted, but which ought not to have been omitted" in his Nosology.

* The pale colour of the evacuations, formerly mentioned by Dr. Good in his definition, is here omitted, as inconsistent with the etymology of the term, and the opinions generally entertained of the nature of the disease.—Ed.

With these occasional dejections of viscid and pitchy bile, and sometimes even without them, there is also frequently a discharge of dark, grumous, chocolate-coloured blood, accompanied with or preceded by a considerable pain in both hypochondria.

[Our author adopted Hoffmann's belief, that, in melæna, the liver and spleen were diseased, and their bloodvessels ruptured. Dissections do not prove the constancy of these circumstances. Dr. Cheyne has known two instances in which inky blood was vomited up, in consequence of long-continued sea-sickness, where no reason existed for suspecting tumour, or obstruction in any of the solid viscera of the abdomen; facts proving, in his opinion, that melæna may depend solely upon an excitement of the inner surface of the stomach. In the melæna cholæa, referred to a flow of ill-conditioned bile, though this fluid may really deviate very much from its healthy quality, this may depend entirely on some modification of secretion quite unconnected with structural disease. Thus, as Andral particularly states, no relation can be established between those alterations of the liver which dissection reveals, and the changes of the bile as detected by various tests. In the great number of diseased states of the liver, attended with change of structure, noticed by this author, the bile in the ducts and the gall-bladder was neither altered in its quantity or qualities. While, in other examples, where anatomy can discover no trace of any change in the parenchyma of the liver, the bile is either more abundant or more scanty than usual, or of a different quality from what it is in the healthy state. "I have," says he, "been surprised at the enormous quantities of bile distending the digestive tube, where scarcely a slight hyperæmia existed in this canal, and the liver seemed in no way changed."—(*Andral, Précis d'Anat. Pathol.*, tom. ii., p. 611.) However, in cases of melæna cholæa, the liver may be diseased, and in the examples which have fallen under the editor's notice, it has generally been so; though it is proper to add, that the subjects of them had all been hard drinkers. In Dr. Markland's case, the liver was smaller than usual, and had a rough shrivelled appearance, with fissures one eighth of an inch in depth. It contained neither blood nor bile, and was of a natural consistence. The spleen contained little blood, but was of the natural size and appearance.—(*See Edin. Med. Journ.*, No. 79, p. 301.) In the third case, recorded by Portal (*Mém. sur la Nature, &c. de plusieurs Maladies*, tom. ii., Paris, 1808), no visceral disease was discovered after death; however, in two other examples described by him, the liver and spleen were diseased. They were also found diseased, as well as the stomach and small intestines, in a case published by Dr. Cheyne (*Dublin Hospital Reports*, vol. i., p. 263), who particularly mentions, that the vessels of the liver and spleen appeared to be destitute of blood. In a curious example of sixteen pounds of melæna found in the colon by Mr. Geoghegan, there were tubercles of the liver, and a stricture of the rectum.

—(*Trans. of the Assoc. Physicians of Ireland*, vol. i., p. 197.)

The above symptoms have been accurately distinguished by Hippocrates, who in consequence hereof has noticed the two following species of the disease, which I have copied with little variation into our Nosological Synopsis, as forming the best arrangement, and giving the best view of melæna that I am acquainted with.

- | | |
|-------------------|-----------------|
| 1. Melæna Cholæa. | Black Jaundice. |
| 2. ——— Cruenta. | Green Jaundice. |
| | Black Vomit.* |

SPECIES I.

MELÆNA CHOLÆA.

BLACK JAUNDICE. GREEN JAUNDICE.

OCCASIONAL DEJECTIONS OF DARK OR PITCHY BILE, INTERMIXED WITH THE FECES; OCCASIONAL VOMITINGS OF YELLOWISH-GREEN AND ACID COLLUVIES; GREAT LANGUOR, OFTEN VERTIGO; HYPOCHONDRIA FREE FROM PAIN, BUT TENDER UPON PRESSURE.

THE liver is here generally diseased in its structure, and a morbid deep-coloured bile, fulvous, greenish, or fuliginous, is discerned instead of the natural excretion; the finer part of the fluid is first absorbed, and afterward the grosser; and what remains becomes still more viscid, more stagnant, and of a deeper hue.

"In the ordinary use of the term," observes Dr. Marcard of Hanover, "black jaundice means nothing more than yellow jaundice of a more than usually deep die; yet when the real disease exists to which this name ought to be

* Dr. Goldie has taken some pains to ascertain precisely what is said about *Melæna vomens* in the treatise ascribed to Hippocrates, and he notices, as a remarkable circumstance, that the ancient description contains not a word respecting the black discharges by stool, which Sauvages and the moderns mention as characterizing melæna. Dr. Goldie states, that our author was evidently mistaken in supposing the two species, melæna cholæa and melæna cruenta, to have their derivation from Hippocrates; and he does not approve of Dr. Good's generic definition, inserted in the former editions, as seeming to rest wholly on the dark hue of the skin, and not that of the discharge from the alimentary canal. The editor certainly prefers Dr. Goldie's description, which runs thus:—"We mean, therefore, by melæna, the occurrence, as a symptom, in any disease, of very dark-coloured, grumous, pitchy, often highly fetid evacuations by stool, commonly joined with sanguineous vomiting; or, we use the word as the name of a disease, in which such evacuations, with or without vomiting of blood, constitute the characteristic symptom. In these two senses authors speak of symptomatic and idiopathic melæna; but even where the latter phrase is with most propriety employed, the hemorrhage may generally be traced to some constitutional disorder, or local organic disease, as its primary cause."—*See Cyclop. of Pract. Med.*, art. MELÆNA.) One objection perhaps may be made to Dr. Goldie's definition, namely, that the discharge, when blackish, generally has no smell, and has not that highly fetid quality which he has specified.—ED.

limited, no practitioner, who closely examines the very dark colour of the skin and of the defluxions, and especially the danger that accompanies it, can avoid concluding that it has something peculiar in its nature, and cannot be merely an intense degree of yellow jaundice. It is highly probable," he continues, "that a part of the dark colour may depend upon the hue of the bile itself in a state of morbid secretion; but, along with this, there is also a very great structural decay in the biliary organs as well; a decay which gives the chief character to the disease; prevents so frequently all beneficial effects from the best medical treatment; and consequently renders the disease so often fatal."—(*Med. Versuche*, &c., Leipsic, 8vo., 1779.)

The green jaundice is sometimes to be found in young persons, but far oftener in the middle and more advanced periods of life. In men it occurs more frequently than in women, probably on account of the greater wear and tear of their constitution, as more exposed to all weathers and all climates; and appears to be less connected with intemperance than the yellow jaundice; and less disposed to terminate in abdominal dropsy.

In many instances, the hardness and enlargement of the liver extend through its entire structure, but are perhaps more frequently confined to some particular part of it. Upon pressing the region of the liver, the patient is commonly sensible of some degree of tenderness, but otherwise he feels no pain whatever, though he has the same distressing itching of the skin which I have already noticed in yellow jaundice; and sometimes a troublesome sensation of heat in the palms of the hands and soles of the feet.

The pulse, as observed by Dr. Baillie, continues "natural, both with respect to strength and frequency, unless some circumstance may have occurred to irritate the constitution for the time." In the more striking cases, however, that have occurred to myself, the pulse has been peculiarly slow, in some instances not amounting at any time to more than fifty beats in a minute, and occasionally to not more than thirty. The stools are generally pale; but, from some irregular excitement of the liver, appear sometimes tinged with bile of a peculiarly dark and pitchy hue; a part of which, from its overflow, rushes into the stomach, and is discharged by the mouth. The urine is deeply loaded with the same, and tinges the linen of a dark tawny hue; it flows freely, and sometimes deposits a pinky sediment.

The appetite varies, not only in different persons, but even in the same. Some patients eat with a pretty good habitual inclination. In others, the stomach is extremely capricious; at one time without any desire for food of any kind, at another only relishing particular kinds; and, perhaps, a few days afterward, evincing a general taste for whatever is introduced upon the table.

In the preceding species, jaundice is not a dangerous disease, except where the substance

of the liver is very generally affected, so as to make an approach to the species before us. In green jaundice the patient rarely recovers. The progress of the disease is always slow, and the patient may labour under it for three, four, five, or even seven years. I have lately lost a patient, who had suffered under it for this last term of time, and was not more than forty-two at his death. He was a captain in the royal navy, of regular habits, who had seen hard service, and been severely tried by a change of climates.

Contrary to what occurs in all the modes of yellow jaundice, the morbid hue is here so deeply rooted in the system that it never quits it. If the patient recover, it may become a few shades lighter, but it never leaves his person altogether, and is always visible in the countenance.

When the pulse has been very slow, I have commonly found it connected with some affection of the head, and particularly apoplectic or epileptic fits.

As there is much obscurity in this disease, its medical treatment is indecisive. Mercurial preparations, which so often aid us in the first species, are rarely of service in the present. Dr. Baillie thinks he has found neutral salts, taken daily as an aperient, of palliative use; but of a radical cure he seems altogether to despair. It has appeared to me, that, though mercury fails when employed alone, combined with antimonials, it is often highly beneficial; and of all preparations of this kind, I have by far preferred the form of Plummer's pill, or, in other words, the submuriate of mercury in union with the precipitated sulphuret of antimony, with a warm stimulant of gum-resin. I have also found unquestionable benefit from a union of alkalis and bitter tonics, particularly the liquor potassæ with infusion of columbo. The aqua regia bath is another tonic well worth trying. I think I have found it serviceable, but have not yet employed it on a scale that enables me to speak peremptorily. Here also, as in spasmodic jaundice, the counter-irritation of the tartar-emetic ointment has occasionally proved highly beneficial. [A medicine, now found to be highly worthy of trial in melæna, is the rectified oil of turpentine, recommended by Mr. Adair (*Medical Facts and Obs.*, vol. iv.), as will be further noticed at the end of the next section.]

SPECIES II.

MELÆNA CRUENTA.

BLACK VOMIT.

OCCASIONAL VOMITINGS AND DEJECTIONS OF GRU-
MOUS BLOOD, INTERMIXED WITH DARK-COL-
OURED BILE; PUNCT, TENSIVE PAIN IN
BOTH HYPOCHONDRIA; COMPRESSIVE PAIN AT
THE PIT OF THE STOMACH, AND FAINTING.

In this species, the organs subservient to the formation of bile are generally in a more decayed condition than in the preceding: and it may hence be contemplated as a disease com-

pounded of *melæna cholæa* and *hæmatemesis atonica*, or passive hemorrhage from the vessels of the liver, spleen, or both; sometimes from those of the stomach.

Little as we know of the exact part performed in the animal economy by these organs, we see enough to convince us, that the functions of the liver and of the spleen are intimately connected; the blood in both is highly carbonated, as even the natural colour sufficiently indicates; and the closest alliance subsists between them. On which account Hippocrates calls the spleen the *left*, and Aristotle the *bastard* liver. It is a singular property of the blood of the spleen, that, like the catamenial discharge, it does not coagulate.

Dr. Home took a like view of this disease: and affirmed it to be produced, not by a mere effusion of bile of a darker colour, as in black or yellow jaundice, but by an effusion of blood also, which, however, he imagined to proceed from the meseraic veins. He relates three cases, in which the disease appeared to be carried off by a critical discharge; the first by a diarrhœa, and the other two by an efflux of sweat and thick urine.

[The preceding observations require some comment. The doctrine, that the disease is invariably connected with a morbid change of the liver and spleen, has been already refuted by a reference to dissections performed by M. Portal and Dr. Markland. The hypothesis also of ruptured vessels in these organs being the source of the blood in the intestinal canal, is very repugnant both to the plain truths of anatomy, and to the facts disclosed in the dissection of persons carried off by the complaint. According to Portal, three kinds of matter are vomited up in *melæna*; blood not changed; blood so changed as not to be recognised; and bile, which may also be of a deep black colour.—(*Mém. sur la Nature des plusieurs Maladies*, 8vo., Paris, 1808.) When the stools are inodorous, and present a yellow colour on being diluted with water, Dr. Brooks sets down the case as a bilious *melæna*, in opposition to the sanguineous.—(*Trans. of Assoc. Physicians of Ireland*, vol. i., p. 148.) Anciently the liver was fancied to secrete a yellow, and the spleen a black, bile; and the inky matter, which is sometimes vomited up, or discharged by stool, was supposed to pass from the spleen into the stomach through the *vasa brevia*. Dr. Home and M. Portal, however, have proved, that the black matter may transude from the minute arteries of the inner surface of the stomach and intestines; and that it frequently is nothing more than blood altered from its natural appearance by some peculiar action of the vessels.]

Dr. Baillie has, in a few cases, found this cocoa-like fluid thrown up in great abundance, where the stomach alone has seemed to him to have been solely affected, and the liver to have been apparently unconnected with it, though he admits the concurrent action of both viscera in other cases. But, in these special instances, there has been a peculiar obscurity or uncertainty, which is sufficient to justify us in not

placing much reliance upon them. In certain cases, Dr. Baillie tells us, the patients were in some months restored to tolerable health; and here it is difficult to speak with precision as to the extent of the disease. In one case, this distinguished practitioner tells us, the stomach was examined after death; it appeared very capacious; but no structural disease, "so FAR AS HE RECOLLECTS," was found either in the stomach, the liver, or the spleen.—(*Lectures and Observations on Medicine, Posthumous*, 8vo., 1825.)

Intemperance, but especially habitual drinking, is the common cause. Besides the symptoms noticed in the definition, it may be observed, that the countenance is chlorotic, and usually full of anxiety; the pulse is quick and feeble; the skin hot and dry; the strength greatly impaired.

As a symptom, this disease is met with in severe attacks of dysentery; but more frequently in those of yellow fever,* and especially that variety or stage of it which by some writers has been distinguished, though perhaps unnecessarily, by the name of *Bulam fever*. In this case, the black matter is often formed in a few hours, and at once thrown in great abundance from the stomach before it has had time to be absorbed and enter into the circulation, so as to produce the true atrabilious tinge upon the skin, which distinguishes the idiopathic malady.

In the case described by Dr. Markland, the whole line of the intestinal canal, in its villous coat, appears, on dissection, to have been more or less gangrenous; and half a pint of black grumous blood was found in the stomach. The liver, as already noticed, was of a pale brown colour, smaller than usual, with a shrivelled fissured surface, without either blood or bile.

In so worn out and exhausted a state of the affected organs, or perhaps of the constitution generally, as this disease indicates, little benefit is to be expected from medical treatment. Our first duty, however, is to clear the impeded passages of the grumous matter that obstructs them; and our next, to prevent as much as possible a fresh flow of it. For the former,

* Black vomit has been repeatedly observed by American practitioners, as occurring in yellow fever as it has prevailed at different seasons, and in various parts of the United States. Dr. Cothveall supposed it to arise from causes connected with a derangement of the biliary secretions (see *Am. Phil. Trans.*, vol. v.); but Dr. Physic concludes more justly, from morbid examinations, that it is a secretion from the inflamed vessels of the stomach and intestines (*New-York Med. Rep.*, vol. v., p. 130); in which opinion Dr. Barton, of New-Orleans, coincides.—(*Am. Journ. of Med. Sci.*, No. xxix., Nov., 1834.) Dr. Lyons, however, thinks (*Lond. Med. and Phys. Journal*, Feb., 1828) that the matter of black vomit is identical with altered blood, and he has produced a fluid perfectly similar to it, by adding muriatic acid diluted with water to blood. Drs. Hosack, Francis, Townsend, and others, have witnessed this species of cœliaca in individuals of depraved habits who have been violently attacked with yellow fever. Sometimes a similar matter is vomited in the acute attacks of marsh fevers.—D.

gentle means, whether in the shape of purgatives or emetics, or both, will answer best; as we have a shattered fabric to work upon, and violence will only add to its weakness. For the second purpose, the alkalis have very generally been had recourse to, sometimes alone, and sometimes in the form of soap; but I have rarely found them of decided benefit. For these I have often substituted acids, and have preferred the vegetable to the mineral, particularly where the constitution has appeared to be broken down generally; as the patient is able to take a much larger proportion of the former than of the latter, because of the corrosive quality which the latter possess; and of the vegetable acids, the fermented or acetous have answered better than the native. Mercurials seem to be of as little service as in the preceding species; except where we have reason to expect a fresh accumulation of the morbid material, in which case they may be employed as a purgative. But between the paroxysms, bitter tonics, as colombo and simarouba, with such gentle exercise as may be engaged in without fatigue,—a light but generous diet, and the use of the Cheltenham waters, are what should chiefly be insisted upon, as best calculated to postpone the fatal issue.

[Our author conceived *melæna cruenta* to be a hopeless case, and when the liver and other viscera are much diseased, the prognosis must certainly be very unfavourable. It is rather extraordinary, however, that he should not have noticed the occasional efficacy of the oil of turpentine. Besides the observations of Mr. Adair and other practitioners in its favour, two cases of *melæna cruenta* cured by it are recorded by Dr. Brooks,* and another by Dr. W. Nicholl.—(Op. cit., vol. iii., p. 274.) The latter prescribed it as follows:—℞. Ol. terebinth. ʒss; syr. papav. alb. ʒj; aq. menth. vir. ʒj. This draught was given five or six times in the first twenty-four hours, and the annexed clyster twice:—℞. Ol. terebinth. ʒj; mucil. acaciæ ʒiiss; decoct. avenæ ʒxii. Afterward twenty drops of turpentine, with four black drops, were given every four hours, and five grains of the blue-pill at night. In addition to the preceding authorities in favour of turpentine, I may add those of Dr. Cheyne and Professor Elliotson. The editor has seen many cases of this disease in the great prisons, where he officiates as surgeon; and in some instances much benefit has resulted from calomel combined with opium, blistering the right hypochondrium, and giving small doses of the sulphate of magnesia in the compound infusion of roses.]

GENUS III. CHOLOLITHUS. GALL-STONE.

PAIN ABOUT THE REGION OF THE LIVER CATERING WITH PAIN AT THE PIT OF THE STOMACH.

* Trans. of Assoc. Physicians of Ireland, vol. i. The following is Dr. Brooks's formula:—℞. Olei terebinthinæ guttas xxv; aq. cinnamomi ʒj; syr. aurantii ʒj. M. Fiat haustus ter die sumendus.—Ed.

ACH; THE PULSE UNCHANGED; SICKNESS; DYSPPEPSY; INACTIVITY; BILIOUS CONCRETION IN THE GALL-BLADDER OR BILE-DUCTS.

In the preceding species we have had occasion to observe, that the bile is frequently found peculiarly viscid or tenacious, either from original secretion in this state, or from an absorption of its finer and more attenuate parts in the gall-bladder or appended ducts. In the disease before us, we find certain portions of it indurated, and assuming a concrete form, often of a crystallized, sometimes of a laminated structure, and perhaps most commonly of both,—evincing a tendency towards crystallized rays in the centre, with concentric laminæ towards the surface.*

[They have generally been considered as closely resembling spermaceti; are soluble in boiling alcohol; in ether; and also very slowly in oil of turpentine. The substance, like spermaceti, was regarded by Chevreul as a peculiar animal principle, and named by him cholesterol. There is, however, another kind of biliary calculus, resembling inspissated bile, but not, like it, soluble in alcohol and water. The two compositions are frequently blended together, forming biliary calculi of intermediate characters.†]

These concretions were supposed by Fourcroy to consist of a resinous matter combined with a peculiar oil, and a certain quantity of albumen, forming three of the constituent principles of bile. All these principles, however, have of late been denied by Berzelius, who has discovered that the bile becomes resinous only in the process of experiment, by supersaturating it with acids, while the material, hitherto regarded as albumen, is nothing more than a small portion of mucus, furnished from the gall-bladder.

In all instances, perhaps, gall-stones are inflammable; and when dry, blaze like wax in the flame of a candle. And in some instances Dr. Darwin suspects them to dissolve in the matter of the feces, and to pass away invisibly. It is possible, however, that the cases here alluded to were only examples of spasmodic jaundice; for nothing but the actual appearance of bilious concretions in the feces can fully prove their existence; while the general symptoms may be produced by other causes. Gall-stones differ in specific gravity: some have been found heavier than water; others a little lighter, bearing the proportion of nine to ten. In colour they are mostly dark brown; a few are white externally, though still brown within.—(Heberden, *Med. Trans.*, vol. ii., p. 137.)

It is possible that minute biliary concretions

* Baillie, *Morbid Anatomy*, fol. 5, pl. vi., p. 109-113. "C'est d'un changement dans la proportion des principes qui composent ordinairement la bile que résulte la formation des calculs biliaires."—Andral, *Précis d'Anat. Pathol.*, tom. ii., p. 614.

† See Brande's *Manual of Chymistry*, vol. iii., p. 187. Professor Orfila first proved that some biliary calculi are essentially composed of picramel.

may be occasionally formed in the penicilli, or the pores of the liver, perhaps in the ducts; but the gall-bladder is the common seat of their origin; and they are here found of every diversified size, from that of a mustard-seed to that of a pullet's egg; often, indeed, not only completely blocking up the cavity, but distending the bladder far beyond its natural dimensions; and the passing such large concretions shows what wonderful efforts nature is capable of making towards freeing herself from a morbid encumbrance; for the natural size of the ductus communis choledochus scarcely exceeds that of a goosequill. The change thus occasioned is often very slow, and consequently accompanied with less derangement of the general health than we should expect; but as the bitter of the bile is produced in the cavity of the gall-bladder, and this cavity is hereby generally obliterated, the bile loses a considerable proportion of its bitter taste; and, possibly from the want of bile in the intestines, the evacuations are very irregular. The gall-stone, thus closely impacted, will sometimes remain quiet, and without being detached, for many years, with only occasional uneasiness in the hypogastric region.

[The circumstances leading to the formation of gall-stones are very imperfectly known; but a life of indolence is remarked to bring on a disposition to them. They are much more frequent in women than men, and are chiefly met with in persons who have passed the middle and active period of life.—(See *Gregory's Elements*, p. 488, ed. 2.)]

"In some patients," says Dr. Heberden, "the jaundice will disappear in two or three days: in others I have seen it continue near a twelvemonth before the gall-stone could pass into the intestine, or fall back into the bladder: nor will this long obstruction of the natural course of the bile have any lasting ill effects, or hinder the patient from being soon reinstated in perfect health after the removal of the obstruction." And as little real inroad upon the constitution takes place, in many instances, from a continuance of the concretion in the gall-bladder; "for many," observes the same excellent writer, "have been opened after their death, in whom a very large stone, or many small ones, have been found, without their ever having had in their lifetime any complaint which could certainly be imputed to this cause. A gall-stone weighing two drachms was found in the gall-bladder of the late Lord Bute, though he had never complained of the jaundice, nor of any disorder which I could attribute to this cause."—(*Med. Trans.*, vol. ii., p. 134.)

The irritation of a gall-stone has occasionally excited inflammation, and, where the gall-stone has existed in the liver, a large abscess; and the inflammation in the latter case assuming the adhesive form, the abscess has opened externally, and the calculus been discharged in this direction, of which a curious example is related by Mr. Blagden.—(*Op. cit.*, vol. iv., art. xvi.) The calculus, on examination, weighed nearly an ounce and a quarter, and was of an

oblong shape. The patient, who was a lady of sixty-six years of age, gradually recovered. [Sometimes a biliary calculus of very large size will produce an adhesion of the gall-bladder to the duodenum, followed by ulceration, by which means the foreign body passes into the bowels, and is voided with the stools. A case satisfactorily exemplifying this fact, is recorded by Mr. Brayne.—(*Med. Chir. Trans.*, vol. xii.) In other examples, however, biliary calculi of enormous size have made their way into the intestinal canal, through the ductus choledochus, of which instances have been published by Mr. Thomas, Dr. Craigie, and others.—(*Edinb. Med. Journ.*, No. 81.) Instances are related by Andral and others, in which one of the biliary ducts, or the gall-bladder itself, gave way, in consequence of the lodgment of a calculus in one of these organs, and the result was a rapidly fatal peritonitis, from effusion of bile in the cavity of the peritoneum.]

From the absence or presence of pain, the rest or transit of the gall-stone, which give rise to a considerable diversity of symptoms, as well as modes of treatment, the genus is divisible into the two following species:—

1. Chololithus Quiescens. Quiescent Gall-stones.
2. ————— Means. Passing Gall-stones.

SPECIES I.

CHOLOLITHUS QUIESCENS.

QUIESCENT GALL-STONE.

PAIN ABOUT THE LIVER, AND AT THE PIT OF THE STOMACH, OBTUSE AND OCCASIONAL; THE BILE LESS BITTER THAN USUAL; THE DEJECTIONS IRREGULAR.

In the quiescent species, the gall-stone remains usually at rest in the gall-bladder or the liver; and whatever be its size, the growth takes place, and the containing organs dilate so gradually as to produce little or no inconvenience. In Dr. Baillie's plates, there is an example of a concretion of the size of a pullet's egg, which filled up the whole of the fundus. Yet so perfect was the adaptation of nature to the case, that the bladder not only became sufficiently enlarged at its base to hold the concretion, but was also sufficiently enlarged immediately above it to form a new reservoir, and contain very nearly the usual quantity, which the gall-bladder is capable of holding in its healthy state.

At times, however, even in this quiescent form of the disease, we meet with some degree of pain; occasionally, perhaps, produced by a sudden deposit of fresh concretescent matter; occasionally, by abrupt starts of some propulsive power which it is difficult to explain; and occasionally by some peculiar and temporary irritation in the coats of the surrounding organ, by which the bowels are apt to be considerably affected.

In this species, however, little medical treatment is necessary: for we have only to correct

the commotion of the alvine canal when thus excited, or to quicken its motive power when sluggish; and to have recourse to anodyne fomentations and narcotics internally, if there should at any time be severe pain. And, by palliatives of this kind, many a patient, as I have already observed, has been enabled to possess a comfortable enjoyment of life to old age, whose gall-bladder has, after death, been found loaded with concretions which, there has been good reason to conclude, had been gradually accumulating for thirty or forty years.

[An interesting case of death from inflammation of the gall-bladder, caused by the presence of a biliary calculus, was published by Dr. Scott of Cupar-Fife.—(*Edinb. Med. Journ.*, No. 83, p. 297.) On dissection, the coats of the gall-bladder were found to be half an inch in thickness; in its cavity was a stone, of about the size and shape of a green olive, with a few ounces of a thin blackish fluid, similar to very black-roasted coffee grounds, or rather to ink diffused through thin mucilage. A similar fluid was vomited up during the patient's indisposition.]

SPECIES II. CHOLOLITHUS MEANS.

PASSING OF GALL-STONES.

PAIN AT THE PIT OF THE STOMACH ACUTE, EXTENDING TO THE BACK; FREQUENT VOMITINGS: DEJECTIONS WHITE, AND AT LENGTH LOADED WITH ONE OR MORE BILIOUS CONCRETIONS.

It is not a little singular that, during the great anguish sustained in the transit of a gall-stone, the pulse is rarely or never quickened. "Inso-much," observes Dr. Heberden, "that this natural state of the pulse, joined with the vehement pain about the pit of the stomach, affords the most certain diagnostic of this illness. I have seen," says he, "a man of patience and courage rolling upon the floor, and crying out through the violence of this pain, which I was hardly able to lull into a tolerable state with nine grains of opium given within twenty-four hours, to which he had never been accustomed: and yet his pulse was all the time as perfectly quiet and natural, as it could have been in the sweetest sleep of perfect health."

Together with the pain at the pit of the stomach, which is acute in almost every instance, there is sometimes a pain also in the region of the liver; and not unfrequently it commences here. For this it is not difficult to account. Membranous canals, with a very few exceptions, are most sensible at their extremities; and an irritation excited in either extremity acts by sympathy upon the other. A stricture in the prostate gland produces pain, while making water, in the glans penis; and, notwithstanding the comparative insensibility of the rectum, which forms one of the exceptions to which I have just referred, faintness at the stomach is almost always accompanied with a relaxation of the sphincter ani, so that the stools issue involuntarily. Now, as a gall-stone is passing, the pain

is greatest on its first entrance into any one of the ducts, or on its reaching the extremity of the ductus communis just before it is disgorged into the duodenum, in consequence of the greater sensibility of these parts. In the former instance, its direct seat is in the origin of the canal, near the liver; in the latter, in its termination towards the pit of the stomach: but as the one extremity acts by sympathy on the other, both these organs must be affected in a greater or less degree; and as the duodenum and stomach possess a finer sensibility than the liver, we perceive readily why the pain is more pungent in the former, than in the latter region. When the concretion has fairly entered the ductus communis, the pain remits, but generally returns with sudden violence on its reaching the duodenal point: and we hence see the reason of that additional attack of severe agony which a patient often sustains, after having flattered himself that the disease was completely subdued. The calculus, when voided, has sometimes been found to measure nearly two inches in its long diameter, and upwards of three inches and a quarter in its widest circumference.—(*Brayne, Medico-Chir. Trans.*, vol. xii., art. 21.)

In the treatment, all that we can accomplish is to ease, and, as far as possible, accelerate the course of the gall-stone. Formerly, when the gall-bladder was suspected to be completely gorged, its walls thickened from long-continued irritation, the concretions too large to be forced forward, and the pain permanent and severe, attempts were made to remove them by a section into the cyst. Bloch (*Medic. Bemerkungen*, No. v.) gives a singular case of this kind, in which not fewer than sixty-two distinct calculi were taken away with success. But in general the operation has not answered, or has been followed by a formation of other crops of concretions; so that Morgagni and many later writers* of eminence have strongly reprobated the use of the knife, and it is rarely or never had recourse to in our own day. In reality there seems to be no just cause for its use. At the time that the gall-stone is in the bladder, to whatever extent it enlarges, the progress of enlargement is slow, and the capacity of the gall-bladder will, in most cases, without much irritation, and sometimes with very little inconvenience, expand to meet its growth: while the moment it has quitted the cyst, and has entered into the duct, it is in vain to attempt to follow it up to any particular spot.

Our best and wisest exertions, therefore, must be of a palliative kind, with a view of easing and quickening the passage of the gall-stone. We have no direct means, however, of doing the last: and all we can hope to accomplish is that of rendering a little collateral assistance to the expulsive efforts which are made by nature herself. The duct becomes dilated by the circumambient pressure of the concretion as it gradually passes forward, urged on by the same action

* De Sed. et Caus. Morb., Ep. xxxviii., art. 52. Sharp's Critical Inquiry, ch. vi. Le Dran, Consultations sur la plupart de Maladies, &c.

that propels the bile in a state of health. Vomiting, therefore, by compressing the whole abdominal viscera, and, particularly, the full and distended gall-bladder and biliary vessels, may afford one means of pushing forward the concretion: but a gentle force, and consequently gentle vomits, will promise fairer than those which act violently. Dr. Darwin affirms, that, in two instances, he saw from thirty to fifty gall-stones voided after taking only an oil vomit. If the patient be of tolerable vigour, and inflammation be apprehended, bleeding should precede the exhibition of emetics. Cathartics, by exciting the action of the intestines, and directly stimulating the mouth of the common bile-ducts, contribute, also, to excite action through its entire range, and thus farther favour the expulsion of the concretion. And as we often find its passage evidently opposed by spasmodic constriction, opium given very freely, and repeated every hour or two, and relaxing the skin by fomentations or the warm-bath, will in such cases be of essential service. Horse-exercise cannot always be made use of: but where it can be submitted to, it is one of the best auxiliaries we can recommend.*

We know of no solvent of biliary concretions worth attending to. The essential oil of turpentine was at one time regarded as a very powerful medicine of this kind; and, as such, was strongly recommended and very generally employed by Van Swieten (*Constit. Epid., Lugd. Batav.*, p. 102), Bloch (*Bemerkungen*, No. v.), Durande (*Obs. sur l'Effi. du Melange d'Ether Sulph. et d'Huile Vol. de Térébinth.*, &c., *Strab.*, 1790), and many other celebrated characters, sometimes alone, but more generally combined with alcohol, or the sulphuric or nitric ether. More recent practice, however, has not justified its possession of this virtue; and if it were ever serviceable, it must have been as an antispasmodic rather than as a solvent. Durande, indeed, seems to have acted upon this view; for his formula consisted of three parts of sulphuric ether to one of the oil. Yet, where there is danger of inflammation, such a medicine must be always too stimulant; and Dr. Percival has good grounds for remarking, that its internal use is productive of mischief.—(*Essays*, ii., p. 232.) It is not often that this disease proves fatal, or even essentially injures the constitution, except where there is an habitual predisposition to the generation of gall-stones, and the frame is worn out by a chronic succession of irritation and pain. [Such predisposition is, perhaps, best

counteracted by the exhibition of alkalis, soap, nitric acid, taraxacum, and the Cheltenham and other mineral waters.]

GENUS IV.

PARABYSMA.

VISCERAL TURGESCEENCE.

KNOTTY OR UNEQUAL INTUMESCENCE OF THE ABDOMEN FROM AN INDURATED ENLARGEMENT OF ONE OR MORE OF THE VISCERA CONTRIBUTORY TO THE DIGESTIVE FUNCTION; DERANGEMENT OF THE GENERAL HEALTH.

This genus is intended to comprise a natural and extensive division of diseases, consisting in an infarcted protuberance of one or more of the collatitious organs of digestion.

The name under which the disease has been described by Hippocrates, is *megalosplanchnus* (*μεγαλόσπλινχνος*) or "big-bowel:" which Cusson and others, on account of its length, have exchanged for *PHYSCONIA*, a word literally importing "inflation;" and so used by both Greeks and Latins. For dismissing the former, there is, perhaps, sufficient reason; but *physconia* ill supplies its place, as conveying no correct or definitive meaning; whence it has been employed by different writers in so loose a manner, as to comprise a variety of organic tumours that have no relation whatever, in origin, position, properties, or mode of cure. The word, therefore, is not worth preserving, either in respect to its primary or general sense: and it is on this account I have ventured to exchange it for *PARABYSMA* (*ΠΑΡΑΒΥΣΜΑ*), from *παράβω*, a genuine Greek term, in use among the Greek classics, and distinctly signifying morbid *congestion*, *coaccervation*, or *infarction*, which is the prominent character of the genus.

All the viscera of the abdomen are subject to an indurated enlargement of this kind from various causes, of which some are common to the whole, and others peculiar to themselves; among the former should be especially noticed that destitution of valves in their veins, and consequently that want of support to the returning column of blood which belongs to the veins that are distributed to more superficial parts. The local causes will be noticed when treating of those enlargements in their respective order. The species are numerous, and may be arranged under the following heads:

1. *Parabysma Hepaticum.* Turgescence of the Liver.
2. ——— *Splenicum.* Turgescence of the Spleen.
3. ——— *Pancreaticum.* Turgescence of the Pancreas.
4. ——— *Mesentericum.* Turgescence of the Mesentery.
5. ——— *Intestinale.* Turgescence of the Intestines.
6. ——— *Omentale.* Turgescence of the Omentum.
7. ——— *Complicatum.* Turgescence compounded of various organs.

* For the treatment of this affection, Dr. Stokes says (*Lond. Med. and Surg. Journal*, March, 1834), "bleed first, then leech, next employ purgatives, and when you have emptied the bowels, have recourse to opium." He remarks, that the employment of emetics is not free from danger, as instances have occurred where their exhibition was followed by rupture of the gall-bladder and fatal peritonitis. "Were I to hazard a conjecture," says he, "I would say, that emetics can be employed with safety only in the early stage of the disease, when there is no obstruction from organic disease; and again, you should never use them when there is evidence of a distended gall-bladder."—D.

SPECIES I.

PARABYSMA HEPATICUM.

TURGESCENCE OF THE LIVER.

HARD TUMOUR IN THE RIGHT HYPOCHONDRIUM, VERGING TOWARDS, AND SOMETIMES APPEARING AT, THE PIT OF THE STOMACH; GENERAL LANGUOR; PALE OR YELLOW COUNTENANCE; DYSPEPSY; DEJECTIONS IRREGULAR, OFTEN WHITISH.

It is necessary to observe, that the word tumour is used in different senses by different writers; commonly importing a morbid, and mostly a circumscribed swelling or enlargement of any organ; but limited by Mr. Abernethy to "such swellings as arise from some new production, and which make no part of the original composition of the body."—(*Surg. Obs.*, p. 68, 8vo., 1804.) This sense, however, he admits to "trespass against the usual import of the word;" and seems even too restricted for his own use; since he is soon afterward obliged, as he confesses, to extend it to enlargements of glands while they still continue to make part of the original composition of the body, and even to perform their function. In the limited sense here aimed at, TUBER would be a far better word than tumour, as less likely to produce confusion, and as already in some degree known to the language of medicine, in a restricted sense, by its diminutive TUBERCLE. In the present work, the term tumour is employed in its ordinary signification.

There is still much difficulty in accounting for the morbid growth of tumours of any kind, and especially of those which constitute the

genus before us; which sometimes are found, on dissection, to consist of an enlargement or extension of the general structure of the affected organ; and sometimes of distinct lumps or tubers of a very different structure, imbedded in the body of the organ, seated on its surface, or merely attached to it by a narrow neck or footstalk.

The simplest mode of conceiving their origin, is by the deposite of some living fluid into a cell of the cellular structure, or the follicular gland of a mucous membrane, possessing an increased excitement by the pressure of the surrounding parts, or from some other cause of irritation. Mr. Hunter believed, as we shall have further occasion to remark when treating of phthisical tubercles, that "the living fluid which has the greatest tendency to assume a vascular structure when thus collected or effused, is the coagulable part of the blood," for which opinion there seems to be great reason.* And hence, those who have chiefly supported his doctrines in our own day, and especially Sir Everard Home (*Trans. of a Soc. for the Im. of Med. and Chirurg. Knowledge*, vol. i., p. 231) and Mr. Abernethy, confine the origin of vascular tuberculous growths to the sanguiferous system, and especially its coagulable part alone; while Dr. Baron has still more lately restricted them quite as absolutely to the absorbent system: contending that "our hopes of being able to avert or cure such maladies must rest upon some other means than those which are merely calculated to subdue vascular action."—(*Inq. into the Nature of Tuberc. Secretions*, &c., p. 122.)

Either of these views appears to be too narrow. Mr. Hunter has sufficiently shown, that a

* To this opinion many pathologists would object. Mr. Abernethy's explanation of the origin of tumours seems to Mr. Lawrence to have been suggested by the statements of Mr. Hunter respecting the production of vessels in coagulated blood, the supposed agency of this process in effecting the union of wounds and fractures, and its occurrence in effusions of blood into serous cavities. "We now know that the adhesion of wounds, and the union of broken bones, are not accomplished in this way; moreover, that these processes take place most readily where no coagula are present. I have never seen any satisfactory proof of blood becoming organized when effused in wounds, bruises, or into serous cavities, or when deposited in aneurismal sacs."—(Lawrence, in *Med. Chir. Trans.*, vol. xvii., p. 8.) Neither is Mr. Lawrence satisfied with the doctrine, that the growth of tumours depends upon the effusion of lymph, from inflammation. "Nothing," says he, "is more common, than the interstitial effusion of lymph, in consequence of inflammation; the substance thus poured out is not formed into tumours; it is absorbed as the inflammation subsides, or its partial organization causes the enlargement and condensation of the affected structure. None of the phenomena usually considered as characteristic of inflammation, are observed to precede the formation of tumours. These growths occur insensibly, and often arrive at a considerable size before persons are aware of their existence."—(Vol. cit., p. 9.) In the Museum of the Royal College of Surgeons are some preparations put up by Mr. Hunter, in proof of coagulated blood becoming vascular, as the vessels appeared to him

filled with fine injection; but, in a conversation which the editor once had with Sir Astley Cooper upon this subject, the latter explains the appearance by the coagula having had lymph effused under and around them, and that the vessels had really extended themselves into the lymph, and not the coagulated blood itself. This view agrees with some experiments related by Gendrin.—(*Hist. Anat. des Inflammations*.) Professor Carswell sees various objections to Mr. Abernethy's view. The latter, we know, "referred all adventitious formations to the coagulable part of the blood as their origin, and fixed their seat in the cellular tissue, in the parenchyma, and on the surface of organs. This plastic substance was supposed by him to be effused under one or other of these circumstances, to become organized, and to derive the materials of its growth from the vascular system of the surrounding parts. It will readily be seen (says Dr. Carswell), that this view of the seat and origin of adventitious formations is both imperfect and inaccurate. Many of these formations are not organized, not tissues, as he believed, and as they were described to be about the same time, by Laennec, but *amorphous* masses, all the changes which they undergo being dependant on the influence of external agents." It is further argued, that Mr. Abernethy's doctrine assigns fictitious characters to these formations, and confounds under the same head diseases of an entirely opposite nature. Various reasons are also given against other theories promulgated by Andral and Cruveilhier.—(See Carswell's *Illustrations of the Elementary Forms of Disease*, p. 2.)—Ed.

living principle appertains to almost all the fluids of the living body that are formed for its accretion, though the animal oil seems to possess less than any of the rest. He has shown it to exist in the chyle; it is known to every one to exist in the semen, and is transferred to the egg when it first drops from the body of the mother, and before a single particle of blood is elaborated. It is this, in truth, which is the instinctive principle of healthy living matter, whether animal or vegetable: instinct itself being nothing more than the simple law of life, or of such living principle in a state of activity or operation, directed to the definite end of completing single organs or the general system, preserving them in health, or reproducing them for future use.

It is hence probable that most, if not all the living fluids, and not merely those of the coagulable part of the blood, or the semen, have a tendency to produce new forms and tissues, and will do so under a particular state of excitement, and if duly supplied for this purpose. So long as a state of health, or the natural law of the instinctive principle, influences them, these productions will be uniform and definite; but if the healthy power decline, and the natural law dependant upon it cease, the action still continuing without a modifying guide, the productions must be indefinite and anomalous in every possible diversity, according to the contingencies by which they are surrounded. And hence, alone, as it appears to me, can we account for the elaboration of all those infinite varieties of fluids or of fabrics which different tumours present to us; and those monstrous attempts at organization which we occasionally meet with in organs of every description, sometimes simulating or even elaborating hair, sometimes flesh or muscular fibre, sometimes brain, sometimes suet, sometimes honeycomb or other cells, sometimes a tooth, or a nail, or various organs of a fetus in a nidus where we should least expect to find it, and marvel with all our might how it could possibly get there. "The tumour," says Mr. Abernethy, "derives its supply of nourishment from the surrounding parts: it seems to live and grow by its own independent powers; and the future structure which it may acquire, seems to depend on the operation of its own vessels." All this is quite correct; and it is the object of the preceding remarks to show from what source it is possessed of such independent powers, and by what means they are rendered subservient to such an infinite variety of sportive and anomalous effects.

We have thus far supposed the morbid growths before us to have issued from the cellular texture, or the serous or mucous membranes of organs. But there is no difficulty in applying the whole of this argument to the substance or parenchyma of organs, as well as to their surface; for effusion may take place in any part of their structure, and the tubercle of the future tumour may consist of a minute drop of such effused fluid within the organized wall, or whatever it be that surrounds or imbeds it. And hence the morbid turgescence may consist either in an enlargement of the general sub-

stance of the viscus, or in parasitic tubers more or less closely connected with its surface. "There seems every reason to believe," observes Dr. Abercrombie, "that the peculiar deposition which constitutes it (tubercular disease) may take place from any tissue of the body: in some cases slowly and gradually; in others, the result of a low inflammatory action of a peculiarly unhealthy character."*

The organ hereby becomes weakened in its healthy action, and consequently is more disposed to fall a prey to whatever vermicles or their eggs are by any means able to obtain an entrance or a deposit in it: and hence it is nothing uncommon to meet with worms of various kinds, as we shall presently have occasion to notice, that have converted one or more tubercles into a nest, or other habitation; and to propagate their kind with great rapidity: and hence more especially the origin of flukes and hydatids in hepatic parabysma. Some constitutions are far more predisposed to such morbid changes than other constitutions; and some animals than other animals. The swine genus more perhaps than any of the rest. It is not, however, easy, and at times is perhaps impossible, to distinguish between simple limpid tubercles in their first formation, and hydatid worms. Dr. Baron has withdrawn himself entirely from the question, and employs the terms almost, if not altogether, synonymously, without venturing to determine upon the animalcular life of what are ordinarily called hydatids, under any form or magnitude. [According to Dr. Baron, the tubercle commences as a vesicle, and is nothing more or less than a hydatid. Dr. Armstrong finds, however, that the vesicular appearance of the tubercle is simply an accidental occurrence, dependant on the texture of the part in which it is placed. Tubercles, he says, may have the vesicular appearance in the lungs; but, if minutely examined, they will be found to be the extremities of the bronchial tubes, or air-cells, into which the peculiar deposit, constituting tubercle, often takes place.†

* On the Nature and Origin of Tubercular Disease. Trans. of the Medico-Chir. Soc. Edin., vol. i., p. 687. The following, as Dr. Carswell conceives, is a correct definition of tubercles, or rather of the tuberculous matter which constitutes the essential anatomical character of those diseases, to which the term tubercular is now exclusively restricted. "Tuberculous matter is a pale yellow, or yellowish gray, opaque, unorganized substance, the form, consistence, and composition of which, vary with the nature of the part in which it is formed, and the period at which it is examined." Dr. Carswell sets down the mucous system as by far the most frequent seat of tuberculous matter; as for instance, the mucous system of the respiratory, digestive, biliary, urinary, and generative organs. It is also formed on the secreting surface of serous membranes, and in the numerous minute cavities of the cellular tissue. One of Dr. Carswell's plates represents tuberculous matter in the substance of the brain and cerebellum, in accidental cellular tissue, and in the blood.—See Professor Carswell's Illustrations of the Elementary Forms of Disease, p. 1.—Ed.

† This statement is confirmed by Professor

On the serous membranes, Dr. Armstrong has never found them to be, strictly speaking, vesicles. He regards tubercles as secretions from the ultimate ramifications of the arteries.—(*Morbid Anat. of the Bowels, &c.*, p. 16, 4to., Lond., 1828.)] Dr. Jenner seems at times to have carried the animalcular hypothesis too far, even admitting that it has a real foundation; and the following passage which contains a valuable piece of natural history, may at the same time form an illustration of this remark. It occurs in a letter to Dr. Baron:—"Nothing is more common than tubercles in the liver, and among other viscera, of the pig: but these for the most part arise from the common hydatids with thin coats, while those which give birth to the term *measley*, are of a different kind. They pervade almost every part of the animal, the heart, the diaphragm, the serous and the mucous membranes, the eyes, &c. The disease proceeds not unfrequently to such great lengths, that from a fourth to an eighth part of the animal is infested with them. The inferior part of the neck and haunches now becomes œdematous, and effusions take place into the cavities. These hydatids differ from the hydatids of the liver, in being of a more diminutive size; they are for the most part not larger than ordinary shot, and to the feel are almost as hard; they differ too in having thicker coats, and consequently have less fluid within them. I have rarely seen them so large as middle-sized peas. Similar to this species of hydatid is that which pervades the interior of the brain of sheep, and appears to be generated on the coats of the ventricles. I have found them adhering to it, and also swimming in the fluid which had been let loose into these cavities, occasioning hydrocephalus internus, vertigo, and death."—(*Baron on Tuberc. Accrctions*, p. 131.)

Now the character of this last hydatid, the *tenia cerebralis* of Leske, has been sufficiently ascertained to admit its animalcular origin; it is rarely larger than a grain of sand, and is furnished with from thirty to thirty-six hooks, by which it fixes itself firmly to the substance of the brain or of its coats, and especially in yearling lambs, producing that staggering or vertiginous disease which is provincially known by the name of *dunt*. It is also highly probable that the first kind of hydatids here referred to are equally entitled to an animalcular classification; but the measley tubercles that form the second seem rather to be an idiopathic disease of the constitution itself, propagating new

growths of the same kind from organ to organ through every part of the animal; and in the pig, as well as in other quadrupeds, well ascertained to be induced in many instances by innutritious food as an exciting cause.

It is conceived by many pathologists, that the intumescences we are now considering necessarily require an inflammatory action of the organ for their production; and that they are, in fact, for the most part, merely results of what is called chronic inflammation. M. Bichat has with great justness controverted this opinion in his remarks on membranous tubercles, that "*foule de petits tubercules blanchâtres qui est si fréquent sur ces membranes*" (*Anat. Gén.*, tom. iv., p. 517); and has said that we must look to another quarter than that of phlegmasiæ for their origin: although he seems manifestly to err in regarding tubercles of this kind as solely capable of originating from serous membranes, and never existing in the subjacent substance of an organ, except towards the last stages of the complaint, in which they are propagated by the cellular texture: being, in his estimation, "*une affection propre à ces membranes; comme les éruptions milières le sont à la surface cutanée, comme les aphtes le sont aux surfaces muqueuses.*" The nature of many of the morbid growths belonging to the present genus will abundantly show that tubercles of all kinds may take their rise from the interior as well as from the surface of organs; as their history will also, that they may originate without any sense of heat or pain, without any augmentation of the pulse, or any other sign of inflammatory action. A certain but low degree of such action may indeed accelerate their growth and augment their number, as one kind of exciting cause; but congestion from weak action is a cause far more frequent; and accidental irritation not much less so. The subject, however, is still a source of controversy; the opinion of M. Bichat that inflammation is not a necessary source of tubercles in any case, being powerfully supported by MM. Bayle, Laennec, Rostan, Louis, Velpeau, and Armstrong; while their origin from inflammation alone is as warmly contended for by M. Broussais and his numerous adherents.

[In particular, the latter is the doctrine adopted by Professors Andral (*Clinique Méd.*, tom. iii.) and Cruveilhier (*Bibl. Méd.*, Sept., 1826); and, as Dr. Alison observes, the testimony of Andral is the more valuable, as his previous opinion in regard to the formation of tubercles appears to have been nearly the same as that of Laennec. The paper and facts by Dr. Alison himself, in support of the same doctrine, are highly interesting.—(See *Edin. Med. Chir. Trans.*, vol. iii., ed. 1828.)

Carswell's researches. "Encysted tubercle has generally been described as existing in the lungs, but I feel perfectly satisfied that the term encysted, whether applied to pulmonary tubercle, or to tubercle in any other organ, is almost always incorrect. In the lungs, encysted tubercle is a deception, the distended walls of the air-cells having, in all probability, in almost every case, been taken for cysts. In the like manner, the dilated bulbous extremities of the biliary system have been described as cysts of the liver containing tuberculous matter."—See Carswell's Illustrations of the Elem. Forms of Disease, p. 1.—Ed.

Dr. Armstrong, who inclines to the opinion of Bichat, has observed, that against the idea of tubercle being simply the effect of inflammation, many facts might be adduced. In numerous instances where tubercular points are scattered over the pleura or peritoneum, the serous membrane is transparent up to these points, and only becomes reddened or opaque when the

tubercle has become progressive or enlarged, so as to act as a local irritant. He considers it probable that tubercle is connected with fibrinous effusion, but that the latter is not necessarily connected with inflammation. He admits that tubercle and inflammation are often co-existent, and so are the hydatid and tubercle occasionally; but co-existence does not imply a direct dependance or relation.*]

This disease originates from different causes, and is marked by symptoms and effects of very different kinds. The diversity of the symptoms however, is not always sufficient to point out the real nature of the swelling, which, in many instances, can only be determined by a post-obit examination. Yet the following varieties may be noticed as frequently distinguishable during life:—

- | | |
|-----------------------|-----------------------------|
| a Coactum. | From simple parenchy- |
| Atonic turgescence. | matous coacervation. |
| β Scirrhusum. | Accompanied with a |
| Scirrhus turgescence. | hard and scirrhus feeling.† |

* Armstrong, Morbid Anat. of the Bowels, &c., p. 17, Lond., 1828.

† Excluding from present consideration chronic hepatitis, treated of in another part of this work, many of the different conditions of the liver seem to be intended to be comprised under these two first divisions; as, for instance, 1. Simple enlargement of the liver, without change of texture; 2. Tubera of the liver, without disease of its structure; 3. The pale degeneration of the liver, consisting of change of colour, without remarkable alteration of texture; 4. Pale colour of the liver, with induration; 5. Dark induration of the liver; 6. Tuberculated disease of the liver; 7. Tubercles and tubera of various characters, diffused through its substance, with disease of the intervening structure. These and other morbid states are excellently described by Dr. Abercrombie.—(See Path. and Pract. Res. on Diseases of the Stomach, Liver, &c., ed. 2, p. 364, et seq., 8vo., 1830.) The black ramollissement or disease, in which the liver is reduced to a dark-coloured mass, of very little consistence, could not, of course, be comprehended under Dr. Good's general definition; neither could the soft, flabby, fatty degeneration of it; but the white encephaloid disease of this organ, corresponding in its nature to fungus hæmatodes, would belong to this place. In considering chronic diseases of the liver, it is necessary to recollect, that this organ consists of a sanguineous or red part, and of a white or yellow, containing bile. Sometimes it is only the red portion that is hypertrophied, so that the organ is enlarged and red; and sometimes the biliary portion, with the bile-tubes in a state of hypertrophy, and then the liver is enlarged and pale. Sometimes without being enlarged at all, it will be pale. The red part is atrophied, the vessels shrink, and the biliary part is either hypertrophied, indurated, or not changed at all. The whole of the liver is sometimes affected in these ways; and, in other instances, only spots, or parts of it. In some situations there may be hypertrophy of the red substance; in others, of the biliary; so as to cause a mottled appearance of the organ when a section is made of it. In what is termed the *gin-liver*, white lines are seen traversing it, and sometimes granules, varying in size from pins' heads to hazelnuts. Professor Elliotson, from whom the editor has borrowed these valuable remarks, adopts Andral's

| γ Chololithicum. | Accompanied with an |
| Gall-stone turgescence. | occasional discharge |
| δ Helminthicum. | of bilious concretions. |
| Vermicular turgescence. | Accompanied with an |
| | occasional discharge |
| | of worms or larvæ. |

The FIRST of these very generally paves a way to one or other of the three ensuing; and is found most frequently in feeble children who secrete little bile. It is also found very frequently in intemperate eaters, and in foreigners who reside in hot climates; a considerable degree of atony being produced in the liver from the exhausting stimulus of the rays of the sun, and an excessive use of spirituous potations.

In a scrofulous habit, a liver thus enlarged and infarcted, is apt to become SCIRRHOUS in children, if not early attended to, as it is also in the gormandizers just alluded to, who have long habituated themselves to the luxuries of the table. Sometimes the scirrhus is confined to a part of its margin; sometimes it appears partially on its surface; sometimes it runs through one or the other, or both its lobes: and sometimes also, the portion that becomes scirrhus evinces a tubercular structure, and consists of clusters of simple tubercles before the scirrhusity takes place.

It is not always, however, that a scirrhus, or even a tubercular structure of the liver occasions its enlargement. In many instances, indeed, it does so; but Dr. Baillie has given examples, illustrated by plates, in which the liver has hereby shrunk into a size considerably below its natural proportion.* This disease may be generally detected by an accurate examination of the hypochondrium with the hand.†

belief, that the free use of ardent spirits induces a chronic change of the biliary portion of the liver, in which it becomes both hypertrophied and indurated. Sometimes the liver is hardened in particular parts of it; but, on the whole, diminished in size. A gin-liver is mostly of a bright yellow colour, and attended with a degree of ascites, and an opacity and hardness of its peritoneal covering.—See Medical Gazette for 1832-3, p. 484.—Ep.

* Morbid Anat., pl. ii., fig. ii., p. 102. In the disease of the liver, described by Laennec, under the name of *Cyrrhose*, from the part looking like a mass of yellow wax, and thought by Cruveilhier to correspond to a tuberculated form of liver disease, spoken of by Dr. Baillie, there is a diminution of the organ, and much deviation of it from its natural shape. It is beautifully illustrated by coloured engravings, in Cruveilhier's Anatomie Pathol., douzième livraison. This pathologist finds that cancerous tumours in the liver are most disposed to form towards its surface, and refers to a case, in which sixteen out of twenty were so situated. The name he assigns to this affection is, "Cancer du foie par masses disséminées." These masses vary in size from that of a milary seed to that of the head of a full-grown fœtus. He includes, however, in his observations, not merely scirrhus tubercles and tumours of the liver, but those of the fungus hæmatodes kind; and what will seem extraordinary to English pathologists, asserts that he has met with both varieties in the same liver.—Ep.

† This shrunken condition of the liver is not

Almost all the affections of the liver appertaining to the division before us appear to owe their origin to atony or hebetude in the organ: and hence the common rise of that VARIETY of turgescence which is accompanied with **BILIOUS CALCULI**. These are sometimes diffused like granules over the substance of the liver, or among the biliary pores; they are sometimes confined to, and load one or more morbid cysts existing in the liver; and are sometimes naked, concrete, and crystallized; of which I have referred to various examples in the volume of Nosology. These are occasionally to be found in the dejections.

In the variety distinguished by the existence of **GRUBS AND WORMS**, the fluke is, perhaps, sometimes to be found even in the human liver. Doever and Clarke, as already observed, assert this, and Darwin confirms their assertion. That they are found in almost all other animals is admitted by every naturalist; although Dr Harrison, of Horncastle, has lately ventured to deny that they are to be traced in sheep in the well-known disease called the rot. But the vermicles chiefly observable in the variety of parabysma before us, are hydatids.

"These," says Dr. Baillie, "consist of spherical bags of a white or light amber colour, more or less transparent, and are lodged in cartilaginous cysts. The cysts are lined with a brownish pulpy membrane, resembling very much the coagululum of the blood; but this membrane is more or less distinctly marked in different cases. The cysts are sometimes surrounded on every side by the substance of the liver, and sometimes are formed at the surface so as to be partially seen without dissection. The hydatids themselves contain a transparent fluid, which is capable of being coagulated by heat and by acids, and sometimes contain also smaller hydatids floating in this fluid. On many occasions very small hydatids are found adhering to the coats of the larger hydatids, and appear to the eye like small pearls. Hydatids of this species seem to be animalcules of a very simple structure; and although they are not often formed in the liver, yet they grow more frequently in this gland than in any other of the body."*

uncommon in those who have long indulged in the use of ardent spirits. Dr. Hosack (*Essays*, vol. ii., p. 332) has related such to have been the fact on inspecting the viscera of the celebrated tragedian Cooke.—See also Francis's Cases of Morbid Anatomy, in the *Trans. of the Lit. and Phil. Soc. of New-York*, vol. i., p. 534. Dr. Francis informs me, that he has repeatedly observed the liver greatly diminished, and of a firm and scirrhous state, in the bodies of gross inebriates, who have died suddenly, and have been dissected for municipal purposes.—D.

* *Morb. Anat.*, p. 107, pl. 6. The kidneys and the liver are the two organs of the body which are most subject to the formation of hydatids. In sheep, they have been observed to have a contractile power; but this has not been noticed in the human subject. They sometimes lie within one another, like pill-boxes; sometimes they are attached to each other by peduncles from within, hanging one within the other; and sometimes they grow to the outside of each other. Sometimes they are attached to the liver externally; but

The hydatids die in process of time like other animal forms, and their place is supplied by their progeny. When they die, the bags and cysts are often broken up, and become frittered into minute tatters and filaments, fragments of which pass occasionally by the biliary ducts into the duodenum; and, being rejected with the feces, are at times mistaken for portions of the villous coat of the intestines.

As this species of parabysma depends almost entirely on an atony of the liver, the intumescence increases in many instances in proportion to that atony, and particularly where debility of the liver is combined with a general debility of the entire system. And hence the liver is frequently known to enlarge in proportion as every other organ becomes torpid and decays. On which account the liver is often found of an enormous size in dropsical patients. Mr. Gooch gives a case in which, during dropsy, it acquired the monstrous weight of twenty-eight pounds.—(*Med. and Surg. Obs.*) Bal-dinger reports another instance in which it reached twenty pounds (*N. Magaz.*, band. vii., p. 275); and Bonet a third in which it weighed only two pounds less.—(*Sepulcr.*, lib. i., sect. xviii.)

In recent stages, and especially in children and young persons, this disease may often be successfully attacked by warm purgatives and tonics, and especially by those valuable alterants that change the action of both the excretory and absorbent system, diminishing the irritability of the first, and restoring the power of the second, and thus reinvigorating them alike.—(*J. Kaemph., Abhandl.*, &c., 8vo., Leips., 1736.) Many of the metallic salts and oxydes have a tendency to do this, and especially those of zinc, copper, iron, and silver. But those of mercury are, for the present purpose, far more valuable than any of the rest. This mineral should be given in mild forms and gentle doses only, so that it may be persevered in for a considerable period of time. The black or red sulphuret of mercury, or the blue mercurial pill, has been employed indiscriminately; but small divisions of calomel, as a grain or a grain and a half a day for an adult, or the compound

generally speaking, are enclosed in a cyst.—(See Elliotson's Lectures, *Med. Gazette* for 1832-3, p. 496; also Cruveilhier's *Anat. Pathol.*, livr. 3.) The editor attended a man in the King's Bench, about two years ago, whose abdomen was occupied by a cyst containing several gallons of hydatids, the size of which varied from that of an orange to that of a pea. As the swelling was attended with fluctuation, a trocar was introduced into it, when nothing was discharged but a trivial quantity of glutinous matter. The cyst, which was found after death to be attached to the liver, is placed in the Museum of the London University. Dr. Elliotson attended a curious case of this kind, in which an ulcerated communication was established between the cyst and the air-passages, through the diaphragm; and consequently the patient used to cough and spit hydatids until she died. For some interesting remarks on encysted tumours of the liver by Mr. Cæsar Hawkins, see *Med. Chir. Trans.*, vol. xviii.—Ed.

calomel pills, in the proportion of five or six grains a day, will often answer much better. In the meantime, an occasional purging must be persevered in; and if worms be suspected in the intestines, they must be removed by the treatment already laid down. I have also found benefit from an application of the emplastrum hydrargyri cum ammoniaco, large enough to cover the entire hypochondrium, or the use of the tartar-emetic ointment, as already recommended in certain conditions of dyspepsy; and, where particular circumstances have prevented me from using this, from sponging the abdomen daily with aqua regia, diluted with about forty times its measure of water, which, as already observed, reduces it to the sourness of weak vinegar.

As far as my own experience goes, I have had so much reason to be satisfied with the good effects of mercury, that I have rarely employed any other medicine; and, though I cannot say, with Dr. Cullen, that its effects are to be ascribed solely to the stimulus it gives "to the excretories, and not at all to any change produced in the state of the fluids," yet the following remark of the same distinguished writer is entitled to general attention: "Universally mercury, in its active state, seems to be a stimulus to every sensible and moving fibre of the body, to which it is immediately applied; and, in consequence, it is particularly a stimulus to every excretory of the system to which it is externally or internally applied. Besides its noted effects upon the excretories of the saliva, it seems to operate upon the whole of those of the alimentary canal. It proves often diuretic; and I have particular proofs of its reaching and acting upon the organs of perspiration. Although it may sometimes operate more upon certain excretions than upon others, it may be presumed that, when any tolerable quantity is thrown into the body, it is in part distributed over the whole; and therefore its medicinal effect is, that it is the most universal aperient and deobstruent known."—(*Mat. Med.*, part ii., chap. xvii., p. 443.)

I have not, however, found that it gains much advantage, at least in the disease before us, by being united with sulphur, or sub-doses of nitric acid, as in the pulvis mercurii cinereus of the late Edinburgh Pharmacopœia; but the sulphurets of antimony seem to increase its effect. M. de Sauvages relates a singular case of this disease, in which this compound effected a cure, upon the authority of M. Broussonet, in whose practice it occurred.—(Class x., Ord. ii., Gen. ix., Physconia, § 3.)

When the disease exists in feeble children, repeated emetics have been of service, by rousing the torpid absorbents of the liver into fresh action. As the use of the prussic acid has of late been revived for several kinds of visceral affections, I ought not to omit stating that, in the form of an infusion of laurel-water (*prunus laurocerasus*), it is said by various writers to have been serviceable in the disease before us, some of whom have tried it externally, others internally, and a few in both ways (*Baylie's*

Pract. Essays; Percival's Pract. Essays, vol. i., p. 36); but, as I know nothing of it from my own experience, I limit myself to giving this hint.

The preparations of iodine have a far better claim to our attention, not only in respect to the present, but to all the species of parabysina, from their peculiar tendency to promote absorption in morbid growths in general. Dr. Baron (*Illustrations of the Inq. respect. Tuberculous Diseases*, 8vo., 1822), who has extended and enlarged on M. Coindet's experiments, thinks there is no medicine that can rival their salutary powers. But we shall have occasion to notice them still further when discussing bronchocele, in which they seem especially efficacious. In every trial, however, whether external or internal, they require more caution than is ordinarily exercised, and should be commenced in very small and circumspect doses.

There is also another remedial plan, which has been greatly praised at various periods, and especially of late, for its certainty of success, and that is, a protracted nausea. In many cases this has been unquestionably, and even eminently, serviceable; and tuberosities of extensive range, and in some instances when seated on the surface of the body, or the extreme membranes, occasionally even those of bronchocele, have been wonderfully diminished, or even entirely removed, in a few weeks.

It is only, however, when the general habit appears good, and the general strength pretty firm, that we can reasonably expect any advantage from protracted nausea; and hence, comparatively, but rarely in the present disease, which, as already observed, is for the most part an effect of laxity of structure, or hebetude of action. Weakly infants and children are far more subject to abdominal enlargements of the kind before us, than those in health; and it is well known that we may at will produce any extent of tubercles in the liver of rabbits, by feeding them with poor or insalubrious food.*

* Under the name of "parabysma hepaticum," Dr. Good seems to have brought together various structural diseases of the liver, the morbid anatomy of which are more particularly described by Laennec, Andral, Abercrombie, Cruveilhier, and other pathologists. "These are diseases," as Prof. Elliotson has observed, "in which you can do nothing more than treat the patient upon the common principles of inflammation, and endeavour to excite absorption by means of iodine and mercury, and support the patient's strength. As to the greater number of them, you cannot, of course, distinguish them during life. You can tell that there is organic disease, by feeling that the liver is very large; and sometimes you find there are tubera, bumps in the region of the liver; but very often it is impossible to say what exact structural disease there is. If you have seen fungus hæmatodes, or scirrhus in other parts of the body, you may suppose the disease to be of the same nature."—(*Med. Gaz.*, 1832-3, p. 486.) Dr. Abercrombie is not so much an advocate for mercury as the generality of practitioners are: for those chronic affections of the liver which are beyond the reach of any human means, he thinks that the treatment should be entirely palliative, consisting of a careful regulation of the diet and

SPECIES II.

PARABYSMA SPLENICUM.

TURGESCENT OF THE SPLEEN.

INDURATED TUMOUR IN THE LEFT HYPOCHONDRUM, VERGING TOWARDS THE SPINE; PALE COUNTENANCE; GENERAL DEBILITY.*

ENLARGEMENT of the spleen is, for the most part, less mischievous than enlargement of the liver; and there is hardly any organ that either nature or art may take so many liberties with, without seriously affecting the general health. It has been found wanting (*Pohl. Pr. Casus anatomicus*, &c., *defecta Lienis*, Lips., 1740); it has been found double (*Schenck*, observ., lib. iii., N. 84; *Cabrolus*, observ., N. 15), and even treble (*Schenck*, loc. citat.);† and, when in a state of disease, in a few rare instances, it

the bowels, with mild tonics, &c. This he conceives to be a point of much practical importance, because these affections often exist for a long time, without materially injuring the health of the patient; and, by treatment entirely palliative, his life may be perhaps prolonged, and certainly rendered more comfortable. But, when such cases are treated actively by courses of mercury, the strength, he says, uniformly sinks in a very rapid manner, and the patient's life is often evidently shortened. In several cases of chronic affections of the liver, accompanied by jaundice, he has seen very good effects from the external use of iodine, 3ss. to ʒj. of hog's-lard.—(See *Pathol. and Pract. Researches on Diseases of the Stomach, Liver, &c.*, p. 386.) Where the liver is enlarged by the growth of acephalocysts in it, the frequency of more than one cyst is a consideration against undertaking any operation for their discharge, and we must agree with Cruveilhier, that the attempt would only be justifiable, when the cyst became adherent to the parietes of the abdomen, or was disposed to make its way outward, and burst of itself. The success which M. Recamier had by puncturing a tumour of this nature, and then employing caustic potassa and injections, is justly considered by Cruveilhier as an exception to what would generally be the result of such practice.—(See *Anat. Pathol.*, livraison 3, p. 3.) The bilious discoloration of the fluid in these cysts, often noticed, is ascribed by this eminent pathologist to the biliary tubes not being obliterated in the part occupied by the disease, the consequence of which is, that they effuse bile into the cavity where the acephalocysts are contained. In the case which he has related, the patient did not die of the disease of the liver, or the ascites, but of a gangrenous affection of the lower extremities, arising from an anasarous distention of the cellular membrane, and the irritation of scarifications.—Ed.

* The spleen sometimes produces an external swelling, without being enlarged; as when fluid in the pleura presses the diaphragm towards the hypochondrium, and forces the spleen from its usual situation. Enlargement of the left lobe of the liver, or of the left kidney, or certain tumours of the peritoneum itself, may have a similar consequence. See Andral, *Anat. Pathol.*, tom. 2, p. 423.—Ed.

† Heusinger, in his *Mem. sur les Monstr. de la Rate*, &c., p. 62, alludes to the existence of seven spleens in a subject; and Otto, in his *Hand. der path. Anat.*, p. 302, mentions a case where twenty-three accessory spleens existed.—D.

has been utterly extirpated without injury,* or has continued of an enormous size for thirty years and upwards.—(*Darw.*, i., ii., iii., 18; *Saur.*, loc. citat.) [But, though the spleen cannot be regarded as a vital organ, or one of much sensibility, it appears, as Dr. Abercrombie has correctly remarked (*Edin. Med. Journal*, No. 80, p. 1), to exert an important influence upon the functions of the stomach. It may, however, only have this influence when diseased, for, according to numerous experiments performed under the inspection of Baron Dupuytren, the spleen may be removed from dogs, and yet such of these animals as recover from the operation, live afterward, without the slightest impairment of their digestion, absorption, circulation, respiration, power of barking, secretions, nutrition, locomotion, sensibility, sensations, instinctive faculties, and generative functions.—(*L. et P. P. Assolant, Recherches sur la Rate*, 8vo., Paris, 1802.) In general, however, in the human subject, the more the spleen exceeds its natural size, and the longer it continues in this state, the greater is the emaciation of the individual, and the impairment of his health. Respiration, digestion, and the functions of the intestinal canal, must, indeed, unavoidably be disturbed by any considerable enlargement of this organ.

The spleen is liable to acute and chronic inflammation (splenitis); to suppuration; † mor-

* Valisneri, *Opp.* iii., p. 123. Bartholin., *Hist. Anat.*, Cent. iv., *Hist.* 51. Ferguson, in *Phil. Trans.* for 1738.

† According to Andral, pus is found sometimes in the form of separate little drops in the midst of the coagulated blood of the splenic cells, and sometimes in more ample collections, constituting true abscesses. Some of these are separated from the parenchyma of the organ by a pseudo-membrane; while around others, nothing of this kind is remarked; the pus and blood having no partition between them. Andral has seen one case, in which about three fourths of the parenchyma of the spleen contained nothing but pus; the fibrous tissue, in contact with it, being in some places unaltered, but in others softened, pulpy, and in progress to destruction. Where the pus had approached the capsule, this was considerably weakened; and it is conceived that if the patient had lived a little while longer, the pus might have escaped into the cavity of the peritoneum. In fact, abscesses of the spleen, having such a termination, are recorded; while others have burst into the stomach, colon, thorax, or urinary organs, or outwardly through the muscles of the abdomen, or back. One fact, well deserving of recollection, is, that the formation of pus in the spleen seems frequently to be simultaneous with suppuration in other viscera. In an example recorded by Andral, the original disease was in the uterus, in the substance of which, and also in its veins, collections of matter were found after death; but abscesses were likewise noticed in the veins of the pelvis, the spleen, lungs, liver, and brain: examples in which pus is observed only in the spleen, are considered by Andral as less frequent. One case of this description is mentioned, which took place in a child three years of age, the spleen being converted into little more than a pouch of matter, with hardly any vestiges of its parenchymatous texture remaining. During life the symp-

tification; tubercular disease, and the slow suppuration usually following that affection. Inflammation may affect either its external peritoneal covering, or its substance, or, as Andral would say, its fibrous tissue.* The first case may be restricted to the investment of the spleen; but, in almost every instance, the peritoneum of the adjacent organs participates in the affection. In peritonitis, also, the external coat of the spleen is inflamed as well as the rest of the peritoneum. Dr. Abercrombie had an opportunity of seeing a spleen that was studded throughout with innumerable tubercles, all in the solid state, in the body of an infant, aged eight months, who died of extensive disease of the bronchial glands. In a more advanced stage, this tubercular affection presents numerous small abscesses, resembling the vomica of tubercular lungs. The disease, however, is usually complicated with tubercular disease in other organs, so that it is impossible to ascertain the symptoms which arise from the affection of the spleen.—(*Abercrombie*, op. cit.) Perhaps the tubercular enlargement may be more disposed to occur in scrofulous constitutions; but it is less frequent than other chronic swellings of the spleen.]

Parabysma splenicum, as a species, is traced under the following varieties:—

- | | |
|-------------------|---|
| α Coactum. | From simple chronic enlargement. |
| β Scirrhusos. | Accompanied with a scirrhus feeling. |
| γ Cartilaginosis. | Accompanied with a cartilaginous induration of the coats. |

The FIRST VARIETY occurs sometimes as a consequence of menostation, or of a peculiar kind of rheumatism; but chiefly after obstinate remittents or intermittents, in strumous or other weakly constitutions, or which have been previously debilitated by intemperance.† [It gen-

erally arises from intermittent fever, but it may take place from other causes, as from suppressions of the menses, or hemorrhoidal discharge. It is also met with, especially in warm climates, in feeble, unhealthy children, and seems to be produced by damp situations and bad nourishment.—(*Abercrombie*, op. cit., p. 411, ed. 2.)] When agriculture was in a ruder state than in our day, and the land left in many parts swampy, and undrained of its stagnant waters; and, consequently, when tertian and quartan intermittents were far more common than they are at present, this disease was also far more frequent and more obstinate. An injudicious and immoderate use of the bark is said also to have contributed to this affection, and very generally to have increased it. And although we meet with no such mischievous

which are far more common, and of higher importance, are situated in the matter itself contained in the splenic cells. Although this matter, this coagulated fibrine, has no distinct organization, it is perhaps more alive than the fibrous tissue around it. More frequently than it, then, it may be affected by irritation; its nutrition may be so altered, that various morbid products are separated from its own substance; and pus, worms, &c., may be generated within it. The primary cause of several of these changes is quite unknown; but there are some others, in which the cause is entirely physical, and more easy of estimation. Thus, certain modifications of colour and consistence, sufficiently remarkable to obtain the name of cancers of the spleen, appear to be simply connected with obstruction of one of the venous branches running more or less directly into the splenic vein. In this case, the detention of a little fibrine in the cells of the spleen would seem, according to Andral's views, to be adequate to lead to such modifications of this fibrine, as may give it a carcinomatous, tubercular, or other morbid appearance, &c. Softening of the spleen he refers to the blood in its cells being fluid; induration, to its dense consistence: change of size, he ascribes to the blood not being returned by the veins with due quickness, or to its deposition in the cells by the arteries, and its subsequent organization and enlargement. Even the formation of pus, he conceives, may arise from changes in the blood, and in the cells of the spleen. In a part of these doctrines, we recognise the Hunterian opinion concerning the vitality of the blood, and its power of producing vessels within itself, when extravasated or stagnant in living textures. Yet, attentively as these opinions have been examined, and compared with the facts disclosed by morbid anatomy, they are far from being confirmed to the extent which Hunter, and especially Andral, would go. When the fibrine of the blood, or coagulated lymph, becomes vascular and organized, it is now most generally believed, that the vessels shoot or grow into it from the adjacent ones. Indeed, Andral, after all, does not quite disregard the co-operation of the surrounding vessels in the work of disease; for, says he, the blood in the cells of the spleen, in consequence of having lost its wonted qualities, may act as a foreign body, and irritate the surrounding parts. Then in the latter may commence a process of reaction, the result of which may be sometimes the adhesion of a morbid part, and its separation by a partition from the rest of the spleen; sometimes its explosion.—See *Anat. Pathol.*, tom. ii., p. 419-426.—Ed.

toms had been, acute pain in the left hypochondrium, continued fever, and some symptoms of irritation of the membranes of the brain. The latter organ, however, as well as the digestive canal, was quite healthy. In some soldiers who had suffered from Walcheren fever, Mr. Wardrop found the spleen reduced to a cyst, full of puriform matter.—See *Baillie's Works*, ed. by Wardrop.—Ed.

* Exclusively of lymphatics and some nerves, only the following elementary parts are found in the spleen:—1. A fibrous tissue forming externally the capsule, and divided internally into a multiplicity of filaments, among which the blood is effused. 2. A vein, which, in the whole of its course, communicates with the cells by large openings, or perforations in its parietes, and whose cavity is at length confounded with the cells themselves. 3. An artery that splits, directly after its entrance into the spleen, into an infinite number of small branches, which cannot be traced far, but appear to be distributed to the parietes of the cells. See Andral, *Anat. Pathol.*, t. ii., p. 416.

† Andral entertains peculiar opinions respecting the origin of diseases of the spleen: some rare ones, he observes, are seated in the parietes of the internal cells, or in the capsule. The others,

effects in the present day, there can be little doubt that there was much ground for such a charge formerly. In intermittent fevers, Peruvian bark, copiously administered, is not an idle medicine; for if it do not assist, it will be sure to injure. And as it was formerly given in large and frequent doses, in districts where the patient was daily exposed to the operation of the same swampy miasm that produced the disease at first, it is difficult to conceive how it could produce any benefit.*

"In enlargement of the spleen," observes Dr. Vetch, in an excellent essay upon the subject (*Medical and Physical Journal*, 1824), and whose professional employment among the British army at Walcheren afforded him a large field for observation on the disease before us, "the patient seldom or never complains of much pain in the situation where it might be expected: his appetite is generally good, yet his powers of assimilation are obviously deficient: he loses flesh, and is incapable of any muscular exertion. His features have a peculiar, dark, bilious, or mahogany hue; but the conjunctiva preserves its white and healthy appearance. Perspiration is in time wholly suspended, and the skin acquires the appearance and feel of satin; the lips are pale, and there is generally much wasting of the gums; the urine is limpid, and secreted very rapidly, but contains little or no urea. The patient's mind is generally morose and desponding." The extremities are commonly colder, and the pulse quicker, than in health, especially towards the evening. [Dr. Abercrombie states, that the bowels are generally irregular, and the motions dark-coloured. There is frequently a dry cough, and, in protracted cases, hæmatemesis, and, at last, general dropsy.†]

One of the most singular facts in the pathology of the spleen, adverted to by the same physician, is the very rapid manner in which enlargement of it sometimes takes place, and the equally rapid manner in which it may subside. Several years ago he saw, along with Dr. Combe of Leith, a seaman who had contracted ague a few weeks before: there was a firm defined tumour in the situation of the spleen, and projecting downwards several inches; in about a week after this visit, the fever had subsided, and the tumour was entirely gone.

* A remarkable case of enlarged spleen, occurring in the practice of Dr. W. M. Lee, of South Carolina, is recorded in the *Am. Jour. of Med. Sc.*, No. xxiv. The spleen, when removed, weighed five pounds and a half, and the disease was not preceded by intermittent fever. The doctor states that his treatment is alternative doses of mercury at night, aided by frictions of tinct. of iodine, or cataplasms of stramonium, as recommended by Dr. Cunningham, of Arkansas.—(*N. A. Med. and Surg. Jour.*, vol. v.) He adds also, that he has cured several cases of splenitis by Fowler's mineral solution.—D.

† On Diseases of the Stomach, &c., p. 412. In other cases, the general health is not much disturbed, though the patients have a sallow appearance; and thus the disease may continue for many years.—Ed.

VOL. I.—P

Probably this variety of parabysma splenicum never depends upon tubercles, though enlargements of the organ, from this cause, are not unfrequent.* Dr. Abercrombie has seen an immense bag of hydatids covered by the peritoneal coat of the spleen, the substance of which was little altered (*On Diseases of the Stomach, &c.*, p. 414); but this also is an affection that has no connexion with ague.]

When this variety of parabysma has occurred in feeble children, it has often been dispersed by emetics given repeatedly, which stimulate the absorbent vessels into increased activity, and act with considerable success, where a persevering nausea might prove highly mischievous.

Cataplasms that excite vomiting have, for the same reason, in many instances, had the happiest effects. They have commonly been made of tobacco; and Mr. Stedman gives instances of its proving an effectual remedy in both the varieties now adverted to, and in an old man as well as in a boy.—(*Ed. Med. Essays*, vol. ii., art. v.) The former had in the first instance been attacked with a general numbness, in consequence of sleeping in the open air in the West Indies, while the serenadas, or night-dews, were gathering around him. This was succeeded by a jaundice, and the jaundice by a parabysma of the liver, in which the spleen also appears to have catenated; the turgescence continuing to increase for five years, in spite of the medicines prescribed for him. A tobacco poultice was at this time applied, and renewed daily for a month. It produced frequent vomitings; but, at the end of the month, the patient was cured. The quantity employed at a time was six ounces: for a child, one ounce is sufficient. Cataplasms of common groundsel (*senecio vulgaris*, Linn.), the erigeron of the dispensaries, are said to prove equally useful by exciting a like effect.

Dr. Vetch, from an extensive experience of

* Andral describes tubercles of the spleen as very rare in adults, but more common in children. They hardly ever occur without presenting themselves also in other parts. He has often noticed them in the spleen of horses; and in monkeys they are said to be even more common than the tubercles to which their lungs are so notoriously liable.—(*Anat. Pathol.*, tom. ii., p. 431.) Besides hydatids, various other kinds of cysts may be formed in the spleen, and chiefly, according to Andral, within its cells. The most simple are small vesicles, full of serum, which are sometimes dispersed very numerous within the spleen. In some instances they are detached from one another; in others, they are in clusters. MM. Andral and Reynaud found them not only in the cells, but also in the veins of the spleen; some of them being loose, while others were connected to the parietes of the cells and vessels by a slender pedicle. Others, again, were contained in the very substance of those parietes. Certain cysts of the spleen are far more complex: Andral has seen a fibro-serous cyst, which was filled with fatty matter, in the midst of which some hairs were observed. In another instance, a serous cyst presented itself, the contents of which resembled honey.—Ed.

its utility in the Island of Walcheren, strongly recommends a weak infusion of the leaves of the *arbutus uva ursi*, which operates beneficially both as a tonic and a diuretic.—(*Med. and Phys. Journ.*, *ut supra*.) An attack of epistaxis, or an appearance of moisture upon the skin, is generally a sign of returning health.

[For an enlargement of the spleen, accompanied with the state of the constitution described by Dr. Vetch, or anæmia, Professor Tomassini has found preparations of iron the best medicines. "It is now generally admitted," says Dr. Abercrombie, "that mercury is uniformly and highly injurious, producing mortification of the mouth and rapid failure of the strength. In the earlier stages, when there is any considerable degree of tenderness, repeated topical bleeding should be employed, followed by blistering or a seton. In other respects, the chief reliance of those who have seen most of the disease, appears to be upon free and continued purging, and especially purgatives combined with tonics. The spleen powder and spleen mixture of Bengal are combinations of rhubarb, jalap, scammony, and cream of tartar, with columbo powder and sulphate of iron. About 20 days are stated by Mr. Twining (*Calcutta Trans.*, vol. iii.), as the period which is generally required for reducing by this treatment a very considerable tumefaction of the spleen, if the case has been recent. Others employ nitric acid with aloetic purges. "The natives of India employ the actual cautery, and a combination of aloes, garlic, and vinegar. They also employ aloes, combined with sulphate of iron. It is probable the external use of iodine might be useful."—(*Abercrombie on the Stomach, Liver, &c.*, p. 412, ed. 2.)]

IN TURGESCENT OF THE SPLEEN, whether originating from the preceding, or produced by a strumous diathesis, the organ sometimes assumes a scirrhus hardness; and, in consequence of this symptom, is often felt more distinctly than in the first variety. It acquires, in some instances, a very large size, though often not so large as the turgescent spleen without scirrhus. Sauvages quotes from Bonet a case, in which, after death, it was found to weigh thirty-three pounds, and to fill the whole of the abdomen. The complaint had lasted seventeen years before the patient died, during nearly the whole of which time she pursued her usual avocations.—(Class x., Ord. ii., *Bonet. ex Hypol. Bosco*.) Dr. Baillie has given other singular examples; in one of which the spleen was three times its ordinary size, of a hard, but uniformly solid texture; not tuberculated, nor disposed to suppurate.—(*Morb. Anat.*, Fascic. vi. Pl. iii.) When suppurating, however, takes place, the abscess is sometimes very bulky; and the quantity of pus lodged in it has amounted to fifteen pints.—(*Hist. de l'Acad. des Sciences*, 1753, p. 196.)

The coats of the spleen are occasionally converted into a soft cartilage, and exhibit a change which is rarely, if at all, found in other viscera. The enlargement in this case, beyond the natural size of the organ, is in general but trifling; and Dr. Baillie records an instance in

which there was a diminution of size; the coats, though sometimes evincing irregularities on the surface, are usually smooth and uniform; and it is by these characters that we can alone judge of the nature of the disease during life. [Littre and Morgagni have seen the peritoneal investment of the spleen partially ossified, and Andral* met with one case, in which this organ was merely an osseous shell, with internal bony partitions, between which there was a small quantity of reddish fluid, resembling turbid wine.—(*Anat. Pathol.*, tom. ii., p. 433.)]

With regard to the treatment of scirrhus spleen, it is not necessary to add to the remarks already offered under the preceding species.

[The whole substance of the spleen is sometimes reduced to a soft mass of a dark colour, resembling a mass of coagulated venous blood, and breaking down under the slightest pressure after its peritoneal coat is laid open. In certain cases it is still softer, and of a pulaceous consistence, or even like a reddish mucus or pus. This change of the spleen is chiefly met with in old persons, or such as have passed the age of forty. Its exact cause is not known; but it has been met with in persons who died with scurvy, or of continued or intermittent fevers; or who had been afflicted with melancholy; had experienced violent pain in the hypochondria and epigastric region; or had had symptoms of melæna; or laboured under ascites. Dr. Abercrombie† suspects, that it arises from inflam-

* In Hecker's *Litterarische Annalen*, Dr. Hackmann has presented his views on spleno-malacia, or softening of the spleen, which has frequently attended epidemic fevers in the north of Germany. Dr. Hackmann thinks that softening of the spleen depends on over-congestion or venous inflammation, which presents two stages, one of irritation or congestion, and one of true softening. The symptoms of the former are fever, vomiting of a clear fluid often mixed with bile, præcordial distress, great lassitude, pains in the limbs, vertigo, and extreme thirst, which, if satisfied, increases the præcordial distress: the abdomen is swelled, soft in the umbilical region, but not tender; pain however is felt when the body is bent and the stomach or spleen is pressed. Pulsation is very sensible in the epigastrium, and as the disease advances, this pulsation extends to the region of the spleen. The stage of softening is shown by the access of typhoid symptoms, and death ensues as in cases of fever, or follows a state of coma resembling apoplexy; this apoplectic state frequently occurs in softening of the spleen. The disease is generally rapid in its progress, and softening may take place in eleven or twelve days; but it is sometimes chronic. In the more severe forms of softening, the spleen bursts spontaneously, without any previous violence, the matter comes into the abdominal cavity, and death speedily ensues. In softening of the spleen, the bulk of this organ is not always much increased, unless the patient have suffered from endemic or remittent fever. Dr. Hackmann mentions eight cases of acute spleno-malacia.—D.

† *Edin. Med. Journ.*, No. 80, p. 2. Andral's reference of this state of the spleen to the condition of the blood in it, has been already noticed; and, in support of his belief, that it does not arise from inflammatory action, he asks whether it ought not

matory action. He has observed it, as the only morbid appearance in some obscure cases, which were fatal, with symptoms referable to the stomach; or frequent vomiting, loss of appetite, tendency to costiveness, &c., the pulse remaining undisturbed.*]

SPECIES III.

PARABYSMA PANCREATICUM.

TURGESCEENCE OF THE PANCREAS.

HARD ELONGATED TUMOUR, RUNNING TRANSVERSELY IN THE EPIGASTRIC REGION; DYSPEPSY; GENERAL LANGUOR.

THE following are the chief varieties under which the species shows itself:—

- | | |
|------------------------|---|
| a Coactum. | Chronic induration or enlargement. |
| Atonic turgescence. | |
| β Calculosum. | Accompanied with calculous concretions. |
| Calculous turgescence. | |

Diseases of the pancreas occur but rarely. [In many points it resembles the salivary glands, to which it is also analogous in the rarity of its morbid affections. This truth is confirmed by

rather to be considered as an emblem of a general change in the whole mass of blood? Hence its common occurrence in scurvy and typhoid fevers. M. Baillie noticed it in the pernicious intermittents of the Campagna of Rome. What, inquires M. Andral, is the cause of these fevers? Is it splenitis? Or rather, is it not the poison of a miasm, which, by changing the mass of blood, must also modify that which is contained in the spleen?—Ed.

* All the diseases of the spleen which have fallen under the observation of Cruveilhier, have exhibited a character of remission, or intermission; a circumstance which he refers to the remission, or intermission, in the functions of this organ. "If," says he, "on the first accession of intermittent fever, it may be questionable whether the spleen has any concern with the disorder, no doubt can exist at a more advanced period. I have attended many of these cases, where each febrile attack was marked not only by the patient's sense of oppression, swelling, and even pain in the spleen, but by an enlargement of it, very manifest to the physician." According to this distinguished pathologist, the induration of the spleen is always accompanied by an increase of its size and specific gravity, and various degrees of fragility, which eventually subside, and are followed by a state of cohesion and compactness, that he has never noticed in any other tissue, excepting the fibrous transformation. In the *ramollissement*, or softening disease, the spleen never becomes so large as when it is indurated; it is not unusual to meet with it above thrice its natural size, though occasionally, in the softened state, it has weighed seven or eight pounds. As for organic diseases of the spleen, such as tubercles, the black degeneration of it, cartilaginous transformation, scirrhous, &c., they are completely irremediable. The same remark applies to collections of hydatids, as far as medicine is concerned; for the only chance of relief must here depend upon their being voided externally, or through some communication formed with the alimentary canal.—Ed.

extensive observation, and when the surrounding viscera are found variously altered by disease, the texture of the pancreas often continues quite healthy. To say, however, that this organ is never diseased, would be incorrect.

Inflammation of the pancreas seems to be a rare disease; but several cases of it are recorded by Barbette, Greizel, Tulpus, and Bartholine, where it was found suppurated and gangrenous. Pain, generally referred to the back, but sometimes resembling colic, attended the disorder. In a few cases, there was vomiting; but it does not appear to have been a common symptom. Guido Patin found an immense abscess occupying the whole of the pancreas. Portal met with a similar case in a man, who died suddenly after two or three attacks of vomiting, followed by syncope. The same pathologist found the pancreas gangrenous in a man who died with obscure pain in the abdomen, accompanied by wasting and occasional nausea and diarrhoea. A gentleman mentioned by Dr. Perceval (*Trans. of the King's and Queen's Colleges*, vol. ii.), had jaundice and bilious vomiting; a tumour appeared in the epigastrium; his strength failed; blood and fetid pus were discharged by stool; and in three months he died, gradually exhausted. The pancreas was found much enlarged, and contained a considerable abscess. The ductus communis was obliterated by the pressure.*

The pancreas sometimes contains calculi. De Graaf found seven or eight in the pancreas of a man, who had long been liable to vomiting and diarrhoea. In one enlarged pancreas, Portal found twelve calculi, some of which were as large as nuts. In a case seen by Dr. Baillie (*Works by Wardrop*, vol. ii., p. 239), the calculi consisted of carbonate of lime; in some other instances, their composition has been phosphate of lime.

Dissections prove, that the pancreas is sometimes changed in its texture, size, and figure, in consequence of chronic diseases; but the symptoms are so vague and uncertain, that those which might serve for discrimination, have not yet been pointed out by the most intelligent physicians. No doubt the chief causes of this difficulty depend upon the deep situation of the pancreas, its inconsiderable size, its little sensibility, and the very important organs by which it is surrounded. The valuable researches of Dr. Abercrombie show the remarkable diversity of symptoms in chronic diseases of the pancreas. Of twenty-seven cases, which he found described by various writers, six were fatal, with gradual wasting and obscure dyspeptic complaints, without any urgent symptoms. In eight there was frequent vomiting, with more or less pain in the epigastric region; and thirteen were fatal, with long-continued pain with-

* Abercrombie, Edin. Med. Journ., No. 79, and Pract. Researches on Dis. of the, Stomach, &c., p. 418, ed. 2. A case in which, on examination after death, the pancreas was found in a state of active inflammation, has been recorded by Mr. Lawrence.—See Med. Chir. Trans., vol. xvi., p. 367.

out vomiting. In some of these, the pain extended to the back; and in others it was very much increased by taking food. In several of the cases, there were dropsical symptoms; and, in three or four, there was jaundice, from the tumour compressing the biliary ducts. In the morbid appearances also there was great variety, the pancreas being in many of the cases much enlarged; in others in a state of scirrhus hardness, with very little enlargement. No distinct relation could be traced between the urgency of the symptoms and the degree of enlargement, which was very considerable in some examples in which the symptoms were slight and obscure; while hardness, with little or no enlargement, was noticed in some other cases, where the symptoms were defined and violent.]

Of the diseases appertaining to the present species, Dr. Baillie never met with more, than the modifications specified at the commencement of this section.

All the ordinary causes that produce ATONY in the liver and spleen may affect the pancreas; but there is one that is peculiar to itself, and that is, an habitual excitement of the excretories of this organ by the daily use of tobacco, whether chewed or smoked, probably from a sympathetic action between the pancreatic and salivary glands, whose functions so closely co-operate, and whose secretions are so nearly alike. Dr. Darwin relates a case of this kind, which terminated in the death of the patient, who had been for many years a great consumer of tobacco, chewing it all the morning, and smoking it all the afternoon.—(*Zoonom*, Cl. i., Ord. ii., ii. 8.) The substance of the gland is generally hardened, though not determinately scirrhus; and its lobular appearance is preserved.*

[With respect to the treatment of enlargements of the pancreas, general and local bleeding, the exhibition of purgatives, the application

of a blister to the epigastrium,* and a course of alterative medicines, especially Plummer's pill, or iodine, afford the best chances of benefit.]

In the calculous variety, the concretions are chiefly, and sometimes altogether, found in the excretory duct of the gland and its branches, which, in consequence, are often very much distended, and occasionally filled with them. They are usually of a white colour and very irregular shape, and by these characters, when discharged by the rectum, may be distinguished from gall-stones. As the duct is less sensible than those of the liver, the kidneys, or the bladder, it is not often that much pain or uneasiness is complained of, even when the passage, upon an examination after death, seems to have been long blocked up, and upon a stretch.

Emetics, and such exercise as gives a general jar to the animal frame, as riding a hard-trotting horse, will contribute towards dislodging the pent-up concretions; and a free use of acids, acidulous drinks, and especially acidulous mineral waters, will have a tendency to dissolve them.†

SPECIES IV.

w PARABYSMA MESENTERICUM.

MESENTERIC TURGESCECE.

INDURATED AND IRREGULAR MASS OF TUMOURS BELOW THE STOMACH, YIELDING TO THE PRESSURE OF THE HAND; PALE, BLOATED COUNTENANCE; ATROPHY; THE APPETITE SELDOM DIMINISHED, OFTEN VORACIOUS.

THIS species shows itself under the following modifications or varieties:—

- | | |
|---------------------------|------------------------------|
| a Helminthicum. | Accompanied with |
| Vermicular turgescence. | hydatids or other worms. |
| β Strumosum. | Accompanied with |
| Scrofulous turgescence. | scrofula; mostly tubercular. |
| γ Scirrhusum. | Accompanied with |
| Scirrhus turgescence. | scirrhus. |
| δ Sarcomatosum. | Accompanied with |
| Sarcomatous turgescence. | fleshy excrescences. |
| ε Steatomatosum. | Accompanied with |
| Steatomatous turgescence. | adipose excrescences. |
| ζ Fungosum. | Accompanied with |
| Fungous turgescence. | fungous excrescences.‡ |

* See Crampton's case, in *Trans. of King's and Queen's College*, vol. ii., p. 138.

† In some Observations on Diseases of the Pancreas and Duodenum (*Med. Chir. Trans.*, vol. xviii.), Dr. Bright mentions, that, in the only three instances of a discharge of matter like adipocire from the intestines, where he had had an opportunity of opening the bodies after death, there was a scirrhus state of the head of the pancreas, and fungoid ulceration of the duodenum. Yet, on other occasions, he had seen similar states of disease of these organs, in which no such fatty evacuation had been observed.—*Ep.*

‡ In one case Mr. Wardrop found the mesenteric glands much enlarged, and converted into a soft

* Dr. Sewall has published (*New-Eng. Journ. of Med. and Surg.*, vol. ii., p. 22) many interesting remarks on the diseases of the pancreas. Scirrhus and inflammation with its terminations in abscess and ulceration, are the most prominent ones. This organ is sometimes much enlarged, and approaches a state of induration, without any sensible derangement of its organization. This, however, seems to Dr. Sewall to be only the commencement of a process by which the natural structure is lost entirely, and the pancreas becomes truly scirrhus. Dr. S. states further, that the most remarkable indications of an enlarged and scirrhus spleen are pain in the epigastrium, vomiting, and acidity of the stomach. Dr. Valentine Mott, in his reflections on the pulsation in epigastrio, considers this affection as arising, among other causes, from enlargement or disease of the pancreas.—(See *Trans. of the New-York Physico-Medical Society*, vol. i., p. 341.) The late Dr. Warren, of Boston, considers a tumour in epigastrio with a strong pulsation as generally attending a scirrhus condition of this gland. This pulsation has not been much noticed; among those who have recorded it we may mention Baillie, Burns, Monroe, and Francis.—(*Trans. of the N. Y. Phys. Med. Society*, vol. i. p. 349.)—*D.*

These varieties are often complicated by a union of one of them with several others. Thus the strumous modification is sometimes found to have sprouted with fungous caruncles; the sarcomatous evinces a scirrhus or indurated texture; and vermicles are occasionally found in most of them. It is chiefly a disease of infancy, and debility is the proximate cause; but the predisposing causes are numerous. Innutritious food, a chronic and exhausting sickness, invagination, an impure atmosphere, a scrofulous diathesis, may all pave the way. And when the chylipoietic organs are hereby weakened, the weakness will soon extend to the mesenteric glands, which will become tumefied, and exhibit a tubercular or other irregular surface to the feel. The symptoms grow daily more manifest; because, as the lacteals which enter them are now obstructed and impervious to the chyle, the whole frame becomes emaciated, the superincumbent fat and muscles waste away, and the coacervated glands rise towards the surface, occupy their place, and are covered with a meager shrivelled skin alone. And hence, any of the varieties of the present species may become a cause of atrophy or tabes; though both these species may also exist without such effect.

A total obstruction, however, to the course of the chyle from a parabysma of the mesenteric glands, does not often occur, certainly by no means so often as is suspected. Mr. Cruikshank admits it to be "possible that children and grown persons may sometimes have died of such obstruction; but," he adds, "in such enlargement of the glands, if they ever take place, we should meet with the stagnation of the chyle in the first set of lacteals; yet I never saw such stagnation on any occasion whatever: but as stagnation of the lymph from obstructed lymphatic glands of other parts is said to have been seen, it may be possible that the chyle, from the causes mentioned, may sometimes have been prevented from getting into the blood-vessels."—(*Anat. of the Absorbing Vessels*, part i., p. 115.)

That a total obstruction to the course of the chyle does not necessarily follow very great enlargements of the mesenteric glands is certain, because many patients exist under this disease for a considerable number of years, in some instances not less than ten (*Sauv.*, cl. x., ord. ii., ix., 6, § 3); and seem, even at last, to be carried off by hectic fever, or some other cause of irritation, rather than by actual innutrition. In perfect quiet, and freedom from exercise of all kinds, and where the form has acquired its full range of growth, it is astonishing to see how very small a portion of food entering into the system is capable of supporting life; a subject we have already touched upon under *limosis ex-pers*; and hence Morgagni and Dr. Hunter are inclined to believe, that in old people the glands

of the mesentery become obliterated; while Ruysch contended that, in the latter part of his life, he lived without his lacteals, and that old people in general do the same.

In most of the varieties before us the tumours are often very bulky and conglobated; and at times composed of, or accompanied with, cysts filled with a limpid fluid. In one instance, related by M. de Sauvages, these amounted to twenty of various sizes; one as large as a child's head, six as large as a man's fist, and the rest equalling hens' and pigeons' eggs. Hence the whole abdomen is in some cases so generally tumefied as to give a semblance of pregnancy, for which the tumefaction has sometimes been mistaken. This is particularly the case with the last variety; and as the appetite, state of the bowels, and bladder are often unaffected, or only affected casually and to appearance capriciously, there is not unfrequently some difficulty in determining between the two. Sometimes the parabysma is peculiarly complicated in its texture, which is glandular, tubercular, scirrhus, and ossific; the glands or tubercles appearing like clusters of walnuts, interspersed with glands of less magnitude, of the size of peas, beans, or filberts; for the origin of which the reader is referred to the remarks under the first species. Dr. Donald Monro gives a case of this kind in a young woman who died of hectic fever in St. George's Hospital in 1771. Upon laying bare the mesenteric glands after death, they were in some places found to resemble spongy carious bones; not consisting of one large firm piece of bone, but of a number of small pieces united by membranes.

The general outline of the medical treatment will run parallel with the plan already laid down for the cure of *parabysma hepaticum*. If worms exist, the course recommended under the genus *HELMINTHIA* should be carried into effect, according to the kind of worm that discovers itself; a light, nutritious food, substimulant with salt and acid or aromatic condiments, should form the daily repast, with a free exposure to pure air, and such exercise as the patient is best able to take without fatigue. Our chief dependance, however, must be on small doses of mercury; a mercurial plaster with gum ammoniac, large enough to cover the entire seat of disease; or a small portion of mercurial ointment rubbed over the abdomen every night and morning with the friction of the hand, continued for at least half an hour or an hour at each time; in which case the friction will be of almost as much service as the mercury. A salivation is not desirable, for it will only add to the general weakness; and hence whatever preparations are made choice of, they should fall short of producing this effect. The less stimulant and heating of the gum-resins will often also be found serviceable; and especially myrrh, either alone or in combination with the fixed alkalis; and especially with some form of iodine, which, whether used externally as an ointment, or internally in the mode of pills or tincture, has a tendency to afford more relief, and prove a better deobstruent in this species of parabysma than

medullary pulp. The patient had died of a large fungus hæmatodes of the thigh. In very rare examples they have been found to contain earthy matter.—See Baillie's Works, vol. ii., p. 180.

in any other. The aperients employed should be gentle; and where calomel is not thought advisable from any particular circumstance that may occur, rhubarb alone, or in union with some of the neutral salts, will usually be found the best medicine we can have recourse to.

Yet, it is only in recent and uncomplicated cases that we can fairly hope for success, let our medical plan be what it may. In the scirrhus, sarcomatous, steatomatous, and especially the fungous modifications, and more especially still, where several of these are playing their parts simultaneously, the art of medicine may possibly retard, but can never entirely ward off, the fate that is approaching, with perhaps a slow, unperceived, and insidious, but, at the same time, with a certain and irresistible stealth of footstep.

SPECIES V.

PARABYSMA INTESTINALE.

INTESTINAL TURGESCENT.

TUMOUR HARD OR CIRCUMSCRIBED, ROUND OR ELONGATED; MOVEABLE UPON THE PRESSURE OF BOTH HANDS; IRREGULAR DEJECTIONS; OBSTINATE VOMITING; PYREXY; AND FOR THE MOST PART EMACIATION.

IN this species the coacervation exists in the coats of the intestines, and consequently is moveable with them. Almost always, however, a slight degree of adhesive inflammation takes place, and the tumefied part becomes united to the superincumbent parietes, or to some other part of the intestinal canal; on which account the disease belongs to the present, rather than to the preceding order. It has chiefly occurred under the two following modifications:—

- | | |
|--------------------------|-----------------------------------|
| a Conglomeratum. | Cohesive and con- |
| Conglomerate turgescent. | glomerated. |
| β Sarcomatosum. | The tumour circum- |
| Sarcomatous turgescent. | scribed, and of a
fleshy feel. |

Morgagni relates a striking instance of the FIRST VARIETY in a man subject to hypochondriacal depressions of mind, as well as to a flux of the hemorrhoidal vessels. Upon an abrupt cessation of the hemorrhage, he soon complained of pains in the abdomen, sometimes sudden and transitory, at other times protracted, but never leaving him intervals of perfect ease. Some months afterward a hardness and swelling were noticeable in the belly, which gradually augmented, and from the pain and emaciation, and almost incessant vomiting with which it was accompanied, at length exhausted and destroyed him. The tumour lay manifest to the sight as well as to the touch, of a circular shape, equidistant from the ensiform process and the navel, in its diameter about eight fingers' breadth. On dissection, the ileum and adjoining portion of the jejunum were found retracted upwards, coacervated, and firmly adhesive.—(Op. cit., tom. ii., ep. xxxix., No. 21, 25.)

[Inflammation of the peritoneal coat of the intestinal canal is very often followed by a close and more or less general adhesion of the bowels

to one another. These adhesions are sometimes so numerous and intimate, that the intestines form only one mass, being inseparably blended with the substance connecting them together, and making, as it were, a kind of tube winding in the midst of the confused mass.—(See *Meckel's Anat.*, translated by Doane, vol. iii., p. 296.)]

The tumour in the SECOND VARIETY is often of an oblong shape, and lies below the hypochondria, inclining towards the epigastric region, prominent, with unequal hardness. Fantoni relates a case of this kind in a boy of a corpulent make, about ten years of age. It commenced with an excruciating pain in the belly, pyrexia, and vehement vomiting, and was soon followed by a tumour of the above description, but seated on the left side, in size resembling a prolapsed spleen. The patient, worn out by the violence of the symptoms, did not long survive. On dissection, every other part being found healthy, the colon under the stomach and towards the left side, for the length of the palm of the hand, was greatly indurated and distended, with a fleshy, fibrous, and peculiarly-thickened tumour, which contracted the diameter of the gut (*Fantoni, Obs. Med. Select.*, obs. ii.); and if the boy had lived much longer, would, in all probability, have adhered like the last to the surrounding parietes.

From the violence of the symptoms, and the little prospect we have of allaying them, this disease is almost hopeless. It commences with a considerable irritability of the part of the intestinal canal that is affected, and the effusion, growth of new matter, distention, and, where it takes place, adhesion, add daily to the irritable state, augment the pain, and keep up the tendency to vomit, and reject whatever is introduced into the stomach.

There are two indications to be followed up, and but two medicines that offer us any chance of success while holding the indications in view. Our first object should be to allay the irritability, and consequently the pain and sickness, which, after a free loss of blood by cupping, can only be attempted by opium given in large and repeated doses, if necessary, to the amount of ten, twelve, or even fifteen grains a day, if the patient be an adult. Ten and twelve grains a day, for three weeks, without intermission, I have myself prescribed, with great comfort to the patient, and without stupor, or even sleep, the night being passed in a kind of refreshing reverie, without a loss of consciousness at any time. The symptoms we thus endeavour to combat not only bring on sure destruction by the exhaustion they produce, but very considerably promote the enlargement of the tumour, and the extent of the adhesions. If we can succeed in keeping these in subjection for a week or two, it is possible that the constitution may be broken in to submit to the new action produced by the change of structure, and the irritability may at length subside.

We should at the same time endeavour to counteract the morbid change of structure, and particularly to arrest its progress; which con-

stitutes our second indication; and this can only be done by mercurial preparations. Small doses of calomel should, for this purpose, be combined with the opium, while mercurial ointment should at the same time be applied, night and morning, to the seat of pain, and persevered in to pyalism: for the case is urgent, and not a moment is to be lost. The warm-bath may perhaps afford a temporary relief; but no permanent good is to be expected from it. The bowels, however, may often be conveniently refreshed and evacuated by emollient, but at the same time laxative injections. For the rest, the treatment may be conducted as already laid down under the first species.

[In this section too many different diseases are comprehended under the two varieties, and the divisions of the subject should have been more numerous. An advantageous basis for them might have been derived from morbid anatomy, by which the various swellings and indurations of each particular texture of the bowels might have been determined. Thus the origin of the scirrhus alteration of the intestines in their vascular coat and glandulæ muciparæ, and its subsequent extension to the mucous and muscular coats, might have been explained as the foundation of one variety. The thickened state, first of the mucous coat, and then of the peritoneal and muscular, from dysentery, with ulceration of the first-mentioned membrane, being only effects, and not the original disease, did not necessarily require description here. But the thickened folds of the mucous membrane, caused by an accumulation of the cellular substance (*Baillie's Works*, vol. ii., p. 159), might have been enumerated as a variety strictly appertaining to this species.

The remark needs scarcely to be made here, that all organized fleshy indurations, thickenings, tubercles, adhesions, scirrhi, and fungoid swellings of any portion of the alimentary canal, must be deemed beyond the power of medicine.]

SPECIES VI.

PARABYSMA OMENTALE.

TURGESCENT OF THE OMENTUM.

TUMOUR INDURATED AND DIFFUSED: FREQUENTLY SPREADING OVER THE WHOLE OF THE ABDOMINAL REGION: DYSPNOEA; EMACIATION.

This species is especially characterized by its extent and the want of a definitive outline, by which it is particularly distinguished from the preceding. It is usually of a complicated texture; infarcted, scirrhus, tuberculate, and cartilaginous. It has been found of various shapes and magnitudes, from a weight of five pounds to that of twenty, twenty-five, thirty, and, in one instance, fifty-six pounds. In the last case, the patient, a female, appeared to be labouring under an ascites, so generally was the abdomen enlarged. She sunk, gradually worn out by atrophy and pains of various kinds; and on examining the abdomen, the tumour, occupying the entire cavity of the belly, instantly

presented itself to view, enclosed in a pretty thick and stout membrane, chiefly adipose, partly scirrhus and glandular, with a cavity in its interior, filled with a sordid and fetid sanies. Laterally and below, it adhered to the surrounding organs only slightly; but was so firmly fixed to the fundus of the stomach and parts adjoining, that it could not be separated without laceration.—(*Greg. Horst.*, prob. x., dec. vi.)

In some instances the hardness has been almost stony (*Panarol.*, pentec. iii., obs. 10), in others osseous (*Mongin, Hist. de l'Acad. des Sciences*, 1732); sometimes loaded with many thousand glandules (*Seger. Ephem. Germ.*); and, in several of these, accompanied with excruciating pains.—(*Huz. Phil. Trans.*, vol. vii.)

Whatever benefit may be expected from medicine, is to be collected from the remarks already offered on the preceding species.

SPECIES VII.

PARABYSMA COMPLICATUM.

COMPLICATED TURGESCENT.

THE BELLY HARD, ELEVATED, AND DISTENDED AS THOUGH PREGNANT, AND OFTEN SUPPOSED TO BE SO; YET MORE OR LESS KNOTTY AND UNEQUAL: RESPIRATION SELDOM IMPEDED: FOR THE MOST PART ACUTE PAIN, NAUSEA, OBSTINATE VOMITING, AND THIRST.

SEVERAL of the preceding species are complicated as to the nature of the tumour with which the respective organ is affected; the present is complicated as being compounded of various viscera, which are affected simultaneously. And hence the symptoms must often differ in different individuals, according to the immediate seat of the disease and the nature of the tumour. The liver is, in perhaps all cases, more or less concerned: sometimes in connexion with the spleen, sometimes with the mesentery, sometimes with the stomach or intestines, and sometimes with all together. Hildanus found the liver so enlarged as to pass beyond the false ribs of the left side, with the spleen equally enlarged (*Cent. ii.*, obs. 45), and fixed to the adjoining lobe of the former organ. Hildenreich, in a woman of forty-five years of age, found the liver scirrhus, weighing fourteen pounds, with a fleshy excrescence in the mesentery, of the size of a child's head. This case was also further complicated with jaundice.—(*Miscell. Nat. Cur.*, Ann. vi., vii.) Bartholine mentions a woman of elegant form, in the flower of her age, attacked with another modification of this disease, which at length destroyed her: all the intestines, liver, spleen, and every adjoining viscus, were found intermixed, and buried in fat; the liver being at the same time enlarged and scirrhus, and filling both hypochondria; the stomach thickened and cartilaginous.—(*Cent. ii.*, obs. 6.)

Dr. Baron has given various examples of the same, both from earlier writers and from his own practice, of which the following is one of the most illustrative: the patient was a girl of about eighteen, and had laboured under the

malady for several months before it proved fatal. "On opening the belly, it was found that the whole of its contents adhered to each other, and to the cavity, in such a manner as to form apparently one solid mass. None of the viscera could be distinguished till the thickened layers of the peritonæum were torn from their adhesions. It was impossible to do this from the intestines, for there the thickening and adhesions had proceeded so far, as to render any attempt at unfolding them impracticable. The mesentery and its glands were in a very diseased state: the latter were about the size of almonds, and had much of the same appearance when cut into. On separating the peritonæum from its adhesions to the diaphragm, the liver was found of a much larger size than natural; it was of a bright copper-colour, and, like the intestines, it had lost its proper texture. The fingers pierced it in every direction without resistance, and it appeared like a part in a state of incipient putrefaction. On cutting through the right lobe, a lumbricus was observed in one

of the biliary tubes."—(*On Tuberculated Accretions*, &c., p. 25, 8vo., 1819.)

Various morbid changes, as adhesions, thickenings, tubercles, granulated masses, ulceration of the bronchial glands, and purulent discharge, were also observed in the thorax: for all the species of parabsysma, when at length accompanied with inflammatory action, are peculiarly apt to spread not only from organ to organ, but from cavity to cavity; and more so from the abdomen to the chest, than the chest to the abdomen.

Other cases of a striking character are referred to in the author's Nosological Synopsis, which might be easily augmented if necessary; but the present are sufficient to give a general view of the nature, gigantic features, and mischievous effects of this monstrous race of diseases: diseases which we can rarely hope to conquer, unless we have an opportunity of strangling them in their infancy; though we may sometimes give a check to their rapid strides, palliate their painful progress, and postpone their fatal triumph.

CLASS II.

PNEUMATICA

DISEASES OF THE RESPIRATORY FUNCTION.

ORDER I.

PHONICA.

AFFECTING THE VOCAL AVENUES.

II.

PNEUMONICA.

AFFECTING THE LUNGS, THEIR MEMBRANES OR MOTIVE POWER.

CLASS II.

PHYSIOLOGICAL PROEM.

BEFORE we enter on the diseases which disturb the function of respiration, and constitute our Second Class, it may be found advantageous to take a brief survey of the general nature of this function, and of the organs which form its instruments.

The respiratory function is maintained by a current of air, alternately thrown into and thrown out of the chest, and is subservient to two important purposes: that of furnishing us with speech, or the means of vocally communicating and interchanging our ideas; and that of carrying off from the blood a gas recrementory and deleterious to life, and possibly of introducing in its stead one or more gases indispensable to animal existence. It is these two purposes that lay a foundation for the two Orders, into which the Class before us is divided; the first entitled PHONICA, comprising the diseases affecting the VOCAL AVENUES; and the second, PNEUMONICA, comprising those affecting the LUNGS, THEIR MEMBRANES OR MOTIVE POWER.

I. At the root of the tongue lies a minute semilunar bone, which, from its resemblance to the Greek letter *v* or *u-pylon*, is called the *hyoid* or *u-like* bone; and immediately from this bone arises a long, cartilaginous tube, which extends to the lungs, and conveys the air backward and forward, in the manner and for the purposes already mentioned. This tube is denominated the trachea or windpipe; and the upper part of it, or that immediately connected with the hyoid bone, the larynx; and it is this larynx, or upper part, that alone constitutes the seat of the voice.

[The larynx is situated on the median line, and consequently, according to the doctrine of Bichat, it is regular and symmetrical in its form, like all the organs of animal life. Considered as the upper termination of the trachea, it forms a striking contrast with the lower extremity of that tube, which, consisting of the bronchi, and concerned merely with the functions of

organic life, is made up of two lateral portions not resembling each other. The lateral portions of the larynx, on the contrary, are exactly similar. This symmetry is necessary for the harmony of its functions; and a discordant voice would inevitably result from different organizations of the two halves of it, or from inequality in the powers of the muscles of its right and left sides.]

The tube of the larynx, short as it is, consists of five cartilages; the largest, and apparently, though not really, lowermost of which produces that acute projection, or knot in the anterior part of the neck, and especially in the neck of males, of which every one must be sensible, and which was formerly denominated *pomum Adami*, as though it had sprung up in consequence of Adam's having eaten the forbidden fruit. This is not a complete ring, but is open behind, the open space being filled up, in order to make a complete ring, with two other cartilages of a smaller size and power; and which, together, form the glottis, as it is called, or immediate aperture out of the mouth into the larynx. Of these three cartilages, the first is named scutiform, or shield-shaped; the other two, arytenoid, or funnel-shaped. A fourth cartilage lies immediately over this aperture, and closes it in the act of swallowing, so as to direct the food to the œsophagus. From its position it is called epiglottis. These four cartilages are supported by a fifth, which constitutes their basis, is narrow before, and broad behind, and has some resemblance to a seal-ring: on which account it is named cricoid, or annular. [It is situated between the two flat plates composing the thyroid or scutiform cartilage; and, upon its elevated posterior margin, the two little arytenoid cartilages are loosely articulated, so as to admit of free motion. The chordæ vocales are the two long edges of the rima glottidis, which meet together in front. They consist of a peculiar elastic substance, and reach

from the forepart of the arytenoid cartilages to the thyroid cartilage. Hence, the size of the rima glottidis must necessarily be altered by every movement of the arytenoid cartilages. In the instrument of the human voice, the chordæ vocales are analogous to the various contrivances for producing vibration in musical wind-instruments.] The larynx is contracted and dilated in a variety of ways by the antagonist powers of different muscles, and the elasticity of its cartilaginous coats: and is covered internally with a very sensible, vascular, and mucous membrane, which is a continuation of the membrane of the mouth.

The form of the glottis, composed of three distinct cartilages, resembles that of a small box, with a minute aperture or rima. In adults this aperture is about ten or eleven lines in length, and two in breadth at its greatest diameter. It is, however, increased or diminished by the action of the arytenoid and cricoid cartilages: and in birds and amphibials, is capable of being so completely closed as to prevent the smallest drop of water from penetrating it, except with the will. In this way frogs confine the air in the lungs, and live without inspiration for considerable time.

[That the larynx is the primary organ, in which the original sound is produced, is proved by the voice being destroyed or modified by certain diseases and accidents. If an opening be made in the trachea below the larynx, so that no air shall pass through the latter, no voice is produced; when, on the contrary, an opening is made immediately above the glottis, the voice is not affected. In Bichat's experiments, when the epiglottis was confined, or even cut away, the voice was not affected by it; though later observations tend to prove, that it really answers a particular purpose in the vocal apparatus, as will be presently specified. When the same eminent physiologist cut through the arytenoid cartilages, or divided the thyroid longitudinally, he found that the voice was annihilated.]

The organ of the voice, then, is the larynx, its muscles and other appendages; and the voice itself is the sound of the air propelled through, and striking against the sides of the glottis or aperture into the mouth. The shrillness or roughness of the voice depends on the internal diameter of the glottis, its elasticity, mobility, and lubricity, and the force with which the air is protruded. Speech is the modification of the voice into distinct articulations in the cavity of the glottis itself, or in that of the mouth or of the nostrils.

There is a difficulty, however, in determining by what means the air is rendered sonorous in the glottis, and various explanations have been offered upon the subject. The oldest is that of Galen, who supposed the calibre of the glottis to be alternately expanded and contracted; an idea revived in modern times by Dodart, who at the same time compares its action to that of a flute.—(*Mém. de l'Académie*, &c., 1700.) A second explanation is that of M. Ferrein, who supposes the variations of sound to depend upon variations of tension and

relaxation in the ligaments of the glottis; and, in this view, such ligaments become vibrating chords, and the entire apparatus approaches the nature of a violin.—(Id., 1741.) A third explanation is that of M. Richerand, who unites the two preceding conjectures, and supposes that the glottis is a wind and a chord instrument at the same time. To these explanations we may add that of Kratzenstein, who regards the glottis, in conjunction with the whole length of the larynx, as a kind of drum (*Tentamen de Natura et Characteribus Sonorum Literarum Vocalium*, 4to., 1781); and that of M. Blumenbach, who views the former in the light of an Æolian harp.—(*Instil.*, sect. ix., x., subsect. 155.)

[Perhaps the organ of the human voice is more correctly compared to a clarinet. The rima glottidis is the mouth-piece of the larynx, and corresponds with the reed in the clarinet, or with the lips of a player upon the flute. In pursuing the same simile, as Mr. Mayo has remarked (*Outlines of Human Physiology*, p. 333), we look for a contrivance, analogous to the stops in the flute or clarinet, by means of which the tube may be shortened or lengthened, and we find the effect produced by the alternate rising and falling of the larynx. When the larynx is raised, the vocal tube is shortened; when it is depressed, the vocal tube is lengthened.]

In forming high, or acute sounds, a contracted state of the glottis, with tension of its ligaments, is required; the air passes rapidly through the narrow opening, and numerous oscillations of its sides are produced. The whole larynx is carried upwards and forwards; and, when the most acute sounds are uttered, the head is thrown backward, in order that the larynx may be elevated through a wider range. This elevation equals nearly half an inch for one octave. That the changes above mentioned take place is proved, by placing the finger on the larynx, and uttering an acute sound, at which period the ascent of the organ may be plainly felt; by the comparatively acute voice of children and women, in whom the larynx is small, and the glottis consequently narrow; by comparative anatomy, which shows us, that the glottis is small and narrow in singing birds; large and relaxed in animals which utter deep sounds; by the blowing of wind instruments, in which the opening for the passage of the air is always contracted in order to produce the high notes; and also by this general fact, that the sounds are always more acute in proportion as these instruments are of smaller size.

In the production of deep or base tones, an opposite state of parts is required: the larynx is carried downwards, and the head itself brought towards the chest. This descent, like the ascent, is about half an inch for an octave. In the male sex, where the larynx is larger, and the glottis consequently more ample than in the female, the voice has habitually a deeper tone. Eunuchs and women may be taught to sing soprano, but not base. When very low tones are formed, in which the chordæ vocales

are greatly relaxed, the production of sound ceases altogether. A human voice that has been much exercised, can pass through about two octaves and a half in either direction from the middle; consequently, it has a range in the neck of nearly three inches. The minuteness of the change, capable of altering the tone, must seem truly wonderful, when we reflect, that the breadth of the rima glottidis does not exceed a line at its broadest part, and that the variety of tones is almost endless.—(See *Art. Larynx in Rees's Cyclopædia*.)

The force with which the air is impelled into the flute, the clarinet, or the larynx, is regulated by the action of the muscles of the chest concerned in expiration.

According to M. Magendie, one use of the epiglottis is to perfect the larynx as a musical instrument. The note of a clarinet, swelled beyond a certain degree of loudness, is apt to break into a higher note; now, M. Grenié discovered, that this imperfection may be remedied by the insertion of a tongue of elastic substance; and, in the organ of the human voice, the epiglottis is precisely such a contrivance.

That much difficulty, however, attends all the foregoing theories, cannot be denied: this is rendered clear enough in a memoir by M. Savart (*Magendie, Journ. de Physiol.*, tom. v., 369), who shows that the analogy between musical instruments and the organ of voice is very imperfect.]

Those animals only that possess lungs, possess a larynx; and hence, none but the three first classes in the Linnæan system, consisting of mammals, birds, and amphibials. Even among these, however, some genera or species are entirely dumb, as the myrmecophaga, or ant-eater; the manis, or pangolin; and the cetaceous tribes; the tortoise, lizards, and serpents; while others lose their voice in particular regions; as the dog is said to do in some parts of America, and quails and frogs in various districts of Siberia.*

It is from the greater or less degree of perfection with which the larynx is formed in the classes of animals that possess it, that the voice is rendered more or less perfect: and it is by an introduction of superadded membranes, or muscles, into its general structure, or a variation in the shape, position, or elasticity of those that are most common to it, that quadrupeds and other animals are capable of making those peculiar sounds by which their different kinds are respectively characterized; and are able to neigh, bray, bark, or roar; to purr, as the cat and tiger kind; to bleat, as the sheep; or to croak, as the frog; which last, however, has a sac or bag, of a singular character, in the throat or cheek, directly communicating with the larynx, on which their croaking principally depends.

The larynx of the bird class is of a very peculiar kind, and admirably adapted to that sweet and varied music, with which we are so often

delighted in the woodlands. In reality, the whole extent of the trachea in birds may be regarded as one vocal apparatus; for the larynx is divided into two sections, or may rather, perhaps, be considered as two distinct organs, the more complicated, or that in which the parts are more numerous and elaborate, being placed at the bottom of the trachea, where it diverges into two branches or bronchiæ, one for each of the lungs: and the simpler, or that in which the parts are fewer, and consists of those not included in the former, occupying its usual situation, at the upper end of the trachea; which, however, is still without an epiglottis; both food and water being, as we have already observed, rendered incapable of penetrating the aperture of the glottis, by another contrivance. The lungs, trachea, and larynx of birds, therefore, may be regarded as forming a complete natural bagpipe; in which the lungs constitute the pouch and supply the wind; the trachea itself, the pipe; the inferior glottis the reed or mouthpiece which protrudes the simple sound; and the superior glottis, the fingerholes which modify the simple sound into an infinite variety of distinct notes, and at the same time give them utterance.

Here, however, as among quadrupeds, we meet with a considerable diversity in the structure of the vocal apparatus, and especially in the length and diameter of the tube or trachea, not only in the different species, but often in the different sexes of the same species, more particularly among aquatic birds. Thus the trachea is straight in the tame or dumb swan (*anas olor*) of both sexes; whilst in the male musical swan (*anas cygnus*), but not in the female, it winds into a large convolution, contained in the hollow of the sternum. In the spoonbill (*platalea leucorodia*), as also in the mot-mot pheasant (*phasianus mot-mot*), and some others, similar windings of the trachea occur, not enclosed in the sternum. The males of the duck and merganser (*anas* and *mergus*) have, at their inferior larynx, a bony addition to the cavity, which contributes to strengthen their voice.

Among singing-birds, Mr. Hunter, who, at the request of Mr. Pennant, dissected the larynx of many distinct kinds, observes that the loudest songsters have the strongest muscles, and that the skylark has the strongest of the whole; his clear and vigorous note is often heard when he can no longer be followed in his ascent by the most penetrating eye. He observes also that, among this division of birds, the muscles of the male, following the same rule, are stronger than those of its respective female, whose voice is always less powerful. In birds that have no natural voice, he perceived no difference of muscular power in the larynx of either sex.

From this more extensive and complicated machinery in the vocal organ of birds, we find numerous species possessing powers of a very extraordinary kind. In many of them, as the thrush and the nightingale, the natural song is exquisitely varied, and through an astonishing length of scale. In the *pipra musica*, or tune-ful manakin, the song is not only intrinsically sweet, but forms a complete octave; one note

* Blumenb. Comp. Anat., ch. xv., § 193. Camper. Phil. Trans., vol. lxi., 1779, p. 139.

succeeding another, in ascending and measured intervals, through the whole range of its diapason. There are various kinds that can imitate the music of human art, and amuse us by acquiring national and popular tunes; as the bullfinch, the linnet, and even the robin, when reared in a state of separation from all other birds; whilst some, again, are capable of imitating human speech, as the parrot, the jay, and jackdaw, and, indeed, most of the *psittacus* and *corvus* genera; a fact, which proves the possession of a powerful and retentive memory, as well as of a precise and delicate ear. A linnet, according to Mr. Pennant, was once taught the same at Kensington; and even the nightingale is said to have talents for speaking equal to those for singing. But where is the man, whose bosom burns with a single spark of the love of nature, who could for a moment consent, that this sweet songster of the groves should barter away the touching wildness of its native notes for any thing that art has to bestow?

Yet, perhaps, there is no species among the class of birds that is more entitled to notice in a physiological survey, on account of its voice, than the *turdus polyglottus*, or mocking-bird. This is a subdivision of the thrush kind; its own natural note is delightfully musical and solemn; but, beyond this, it possesses an instinctive talent of imitating the note of every other kind of singing-bird, and even the voice of every bird of prey, so exactly as to deceive the very kinds it attempts to mock. It is moreover playful enough to find amusement in the deception; and takes a pleasure in decoying smaller birds near it by mimicking their notes, when it frightens them almost to death, or drives them away with all speed, by pouring upon them the screams of such birds of prey as they most dread.

Now it is clear that the imitative, like the natural voice, has its seat in the cartilages and other moveable powers that form the larynx; for the great body of the trachea only gives measure to the sound, and renders it more or less copious in proportion to its volume. It is not therefore to be wondered at, that a similar sort of imitative power should be sometimes cultivated with success in the human larynx; and that we should occasionally meet with persons who, from long and dexterous practice, are able to copy the notes of almost all the singing-birds of the woods; or the sounds of other animals; and even to personate the different voices of orators and other public speakers.

One of the most extraordinary instances of this last kind, consists in the art of what is called *VENTRILLOQUISM*, of which no very plausible explanation has hitherto been offered to the world. The practitioner of this occult art is well known to have a power of modifying his voice in such a manner as to imitate the voices of different persons conversing at some distance from each other, and in very different tones. And hence, the first impression which this ingenious trick or exhibition produced on the world, was that of the artist's possessing a double or triple larynx, the additional larynges being supposed

to be seated still deeper in the chest than the lowermost of the two that belong to birds; whence, indeed, the name of *VENTRILLOQUISM*, or *BELLY-SPEAKING*. This rude and early idea M. Richerand was at one time strongly tempted to revive; but a closer examination of the subject convinced him that it could not be supported, and he abandoned it, without, however, offering any other sufficiently matured for examination. Mr. Gough has attempted, in the *Memoirs of the Manchester Society*, to resolve the whole into the phenomena of echoes; the ventriloquist, on this hypothesis, being conceived to confine himself on all occasions to a room well disposed for echoes in various parts of it, and merely to produce false voices by directing his natural voice in a straight line towards such echoing parts, instead of in a straight line towards the audience; who, upon this view of the subject, are supposed to be artfully placed on one or both sides of the ventriloquist. It is sufficient, in opposition to this conjecture, to observe, that it does not account for the perfect quiescence of the mouth and cheeks of the performer while employing his feigned voices; and that an adept in the art, like M. Fitzjames, who exhibited a few years ago in our own country, or M. Alexandre of the present day, is totally indifferent to the room in which he practises, and will readily allow another person to choose a room for him. Of M. Fitzjames, M. Richerand has given a particular account from personal examination. He observes, that he always made a strong inspiration before he commenced his performance, and could support his various voices till he required a fresh supply of air; thus evidently proving that the inhaled air was expired, though not through the lips, but, as appears from another case, observed by M. Richerand, at least partly through the nostrils.

Yet the means by which the ventriloquist is enabled to modify his articulations into the semblance of distinct voices, still remains to be explained; and I shall hence beg leave to throw out a suggestion upon the subject. From various concurrent facts, ventriloquism appears to be an imitative art, founded on a close attention to the almost infinite variety of tones, articulations, and inflexions which the glottis is capable of producing in its own region alone, when long and dexterously practised upon; and a skillful modification of these vocal sounds, thus limited to the glottis, into mimic speech, passed for the most part, and whenever necessary, through the cavity of the nostrils, instead of through the mouth. It is possible, however, though no opportunity has hitherto occurred of proving the fact by dissection, that those who learn this art with facility, and carry it to perfection, possess some peculiarity in the structure of the glottis, and particularly in respect to its muscles or cartilages.

In singing, every one knows that the glottis is the only organ made use of, except where the tones are not merely uttered but articulated. It is the only organ employed, as already observed, in the mock articulations of parrots, and other imitative birds; it is the only organ of

natural cries, constituting the language of all animals possessing a voice; and hence Lord Monboddo has ingeniously conjectured, that it is the chief organ of articulate language in its rudest and most barbarous style. "As all natural cries," says he, "even though modulated by music, are from the throat and larynx, or knot of the throat, *with little or no operation of the organs of the mouth*, it is natural to suppose, that the first languages were, for the greater part, *spoken from the throat*; and that what consonants were used to vary the cries, were mostly *guttural*, and that the organs of the mouth would at first be but very little employed."—(*Orig. and Prog. of Lang.*, vol. i., b. iii., ch. 4.) To which I may add, that notwithstanding, in the ordinary use of speech, the tongue takes an auxiliary part among mankind, yet the numerous and well-authenticated examples on record, and to which we shall have occasion to advert more minutely hereafter, of persons who have retained a full and perfect command of speech, after the tongue has been destroyed or extirpated, proves, incontrovertibly, that the glottis alone is capable of supplying, in this respect, the place of the tongue, upon particular occasions, and where perhaps peculiar pains are taken to call forth the full extent of its latent powers.

This explanation, which some hundreds of persons in this metropolis may remember to have been advanced by the author, in a public lecture on the subject, delivered in the year 1811, has since been embraced in France, though without adopting the hint, that the full perfection of the art may possibly depend upon some slight addition to the muscular organism of the glottis, in those who are thus highly endowed with it. And hence M. Magendie asserts, that ventriloquism consists in nothing more than a delicate attention to the different effects or modifications of sounds or speech, thrown at different distances and through different modes of conveyance, and an exact imitation of them in a larynx of common formation and powers.

"Les fondemens sur lesquels repose cet art sont faciles à saisir. Nous avons instinctivement reconnu, par l'expérience, que les sons s'altèrent par plusieurs causes; par exemple, qu'ils s'affoiblissent, deviennent moins distincts, et changent de timbre à mesure qu'ils s'éloignent de nous. Un homme est descendu au fond d'un puits; il veut parler aux personnes qui sont à l'ouverture: sa voix n'arrivera à leur oreille qu'avec des modifications dépendantes de la distance, de la forme du canal qu'elle a parcouru. Si donc une personne remarque bien ces modifications, et s'exerce à les reproduire, il produira des illusions d'acoustique, dont on ne pourra plus se défendre, qu'on ne peut pas voir les objets plus gros lorsqu'on les regarde à travers un verre grossissant; l'erreur sera complète s'il emploie d'ailleurs les prestiges convenables pour détourner l'attention.

"Plus l'artiste aura de talens, plus les illusions seront nombreuses: mais il faut se garder de croire qu'un ventriloque produise les sons vicaux, et articule autrement qu'une autre per-

sonne. Sa voix se forme à la manière ordinaire. Sous un certain rapport, on peut dire que cet art est à l'oreille ce que la peinture est pour les yeux."—(*Physiologie*, tom. ii., p. 235.)

But this last view of an ordinary articulation and formation of the voice, is at variance with that perfect quiescence of the muscles of the cheeks and lips which the more skilful ventriloquists evince, and which can only be accounted for by a formation of articulations, and not merely a modification of sounds in the larynx.

II. The lungs, whose vessels receive the air from the trachea, and in which the blood undergoes the important process of ventilation, are well known as a pair of large, light, elastic, and spongy organs, suspended by the tracheal tubes and large bloodvessels in the cavity of the chest, and in size adapted to the two sacs of the pleura, which they completely fill when inflated. They are surrounded by an exquisitely fine duplication of this delicate membrane, which lines the entire cavity of the thorax, and separates the lungs from each other by a process or septum; which from its running between the two, is called mediastinum. [The same points of the two layers of the pleura are not always applied to each other; for when the lung expands, it slides upon the pleura costalis (*Mayo's Outlines*, p. 85); a fact proved by the elongation of the adhesions, so frequently existing between the lungs and inside of the chest.] The substance of the lungs is lobular; the larger lobes dividing into smaller, and the subdivision being continued through an almost infinite series, till the ultimate lobules terminate in very minute vesicles; which, after birth, though not antecedently, are filled with air, conveyed by an innumerable host of exquisitely slender ramifications from the two grand branches into which the trachea at first forks off, so as to form a main division for each of the lungs, and which are denominated bronchiæ, as their subdivisions are bronchial vessels. The vesicles or air-cells are invested and held in connexion by the mucous web, common to all animal organs, which, at the same time that it unites them and forms their boundaries, opens a communication between the one and the other, and is itself freely supplied with exquisitely fine bloodvessels, that are ramifications from the pulmonary artery, and continue to divide and subdivide, till they at length form a beautiful network upon the sides of the air-cells, and ultimately become invisible from their attenuation; by which means every particle of blood is exposed, in its turn, to the full benefit, whatever this may consist in, of the gases of the atmosphere, contained in the air-cells which they thus surround.

[Magendie found the air-cells smaller in infants than adults, and less in adults than in persons of advanced age. It further appears that, as we grow older, the specific gravity of the lungs diminishes; and so remarkable is this change, that a piece of lung taken from a man sixty years of age, was fourteen times lighter than a portion of lung of equal size taken from a child.—(*Journ. de Phys. Expér.*, t. i., p. 78–80.)

This increase in the size of the air-cells is

generally so regular, that the age of the subject may be determined by it. However, in old persons, who retain their *embonpoint*, whose muscles are large, and whose hearts are necessarily of considerable size, the air-cells do not undergo such an increase of dimensions. But the contrary happens in very thin old persons of broken constitutions, in whom the heart is almost always diminutive, and the quantity of blood scanty.

The size of the air-cells is also modified by disease. In individuals who have coughed a great deal previously to death, they are generally larger. When such persons are aged, the air-cells may be even two lines in diameter, without any vestige of laceration. The healthy lung of certain individuals affected with phthisis on one side only, was found, when inflated and dried, to resemble light froth.

The preceding change in the texture of the lungs with the progress of age, has the effect of really lessening the number of capillary vessels, by which the blood from the right ventricle is transmitted into the pulmonary veins. In other words, the surface by which the venous is converted into arterial blood, and from which pulmonary exhalation takes place, is thereby diminished. The only remedy for this imperfection would be a quicker pulse, in order that as much blood might be sent in a given time through the lungs of an old, as through those of an adult subject. But unfortunately, as Magendie has observed, the heart beats more slowly in the aged than in other individuals. From these facts it seems probable that the old person must consume less oxygen than the young; that his animal heat must be less; and his ability to resist cold very inferior.]

The moving powers of the lungs consist in the bones, cartilages, and muscles by which they are encircled. The bones are the ribs and sternum, which, in their form, insertion, and general freedom of play (for even the sternum itself seems to yield a little), exhibit a perfection of art that the most careless among us cannot but admire, though the wisest could not have contrived :

“Deus, Deus, ille, Menalca!

Antecedently to birth, the whole of this machinery, with the bloodvessels, may be contemplated as at rest, and the lungs in a state of collapse, in whose interstices there is a perfect vacuum. From the moment the infant becomes exposed to the atmosphere, the air, which presses forcibly on every side, presses also upon the upper part of the trachea through the channels of the mouth and the nostrils; the motive powers of expansion, and which are afterward those of expiration, are immediately stimulated into action; the ribs rise by the agency of the intercostal muscles, and the chest becomes elevated; the diaphragm, whose broad and muscular septum divides the thorax from the abdomen, sinks, from instinctive sympathy, towards the viscera beneath, and the chest becomes deepened; and into the dilated vacuum, hereby produced, the external air rushes forcibly by the

trachea, and, by inflating the lungs to the full stretch of their elasticity, compresses all the surrounding organs. Yet, as the force with which the air operates is very considerably less than that of the heart when stimulated to contract, the blood, instead of being hereby impeded in its course through the pulmonary vessels, flows far more freely, and dilates these vessels by its plenitude, as they are already necessarily elongated by the expansion of the lungs; and the heart in this manner becomes liberated from a load which, if it were to remain in its cavity, would oppress it, and put a stop to its action. And hence we behold at once the important connexion that exists between the sanguiferous and the respiratory systems, and how much the soundness of the one must depend upon that of the other.

Such, then, are the chief motive powers concerned in the act of inspiration, and the means by which they effect their purpose. The process of expiration, or that of throwing the air back again after it has accomplished its intention, is not of more difficult comprehension. [The muscular contraction of the diaphragm and intercostals having ceased, is succeeded by a short relaxation, the elasticity of the cartilages of the ribs and texture of the lungs, occasionally aided by the muscles of the belly and loins, reduces the chest to its former dimensions; and as the capacity of the lungs is thus diminished, some of the air in them is expelled. In a little while the contraction of the diaphragm and intercostals is renewed, and is again followed by relaxation; this alternative proceeding as long as life continues.]

Now this is precisely the state of the moving powers of the lungs, in the two alternate actions of inspiration and expiration. For while the muscles we have just adverted to are stimulated to expand the chest, there are others that, by a reverse energy, are perpetually striving to contract its diameter. Almost all the abdominal muscles tend to produce this effect, and particularly the oblique, straight, and transverse. Many of these are inserted into the ribs; and, as the latter become elevated, endeavour to draw them back into their anterior situations, to which also the ribs themselves have an inherent inclination to return, from their natural elasticity. Other muscles, urged into action by the descent of the diaphragm, immediately contract their fibres, diminish the convexity of the abdomen, and hereby force the abdominal viscera upwards and backwards against the diaphragm that thus intrudes upon them, and drive it into its former position; while all the bloodvessels, and even the air-cells of the lungs, possessing an elastic power, have a natural tendency to return to their smaller diameters; and hence expiration is performed with even more facility than inspiration, and is consequently the last action of dying persons.

The most important power in the act of expiration is, unquestionably, the diaphragm; and on this account Dr. Carson, omitting all consideration of its auxiliary muscles, regards this as the sole antagonist to the expansive energy of

the lungs. "Two powers," says he, "are therefore concerned in regulating the movements, and in varying the dimensions and form of the diaphragm,—the elasticity of the lungs, and the contractile power of the muscular fibres of the diaphragm. Of these powers, the one is permanent and equable; the other variable, and exerted at intervals. The contractile power of the diaphragm, when fully exerted, is evidently much stronger than its antagonist, the resilience of the lungs; but the latter not being subject to exhaustion, takes advantage of the necessary relaxations of the former, and, rebounding like the stone of Sisyphus, recovers its lost ground, and renews the toil of its more powerful opponent." This is a correct statement, so far as it goes; but the collateral powers, called into action in the expulsion of the air from the lungs, should not be overlooked in a general outline of the entire economy of respiration. In effect they are slightly hinted at, though not described, in the passage which immediately follows, in which we are told that "breathing is in a great measure the effect of this admirable contest between the elasticity of the lungs and the irritability of the diaphragm."*

[In ordinary breathing, expiration is conceived by some physiologists to be, in a great measure, a passive operation, depending principally upon the elasticity and other physical properties of the organs concerned. This, however, is supposed to be the case only in the quiescent easy state of respiration, without exertion. Though the function cannot be altogether suspended by any voluntary effort, the degree in which it is carried on may be influenced and altered by the will. Thus, as Dr. Bostock notices, when we wish to make a full inspiration, we call into action, besides the diaphragm and intercostals, the external muscles of the breast, shoulders, and other neighbouring parts, which, by elevating the ribs and the sternum, increase still further the capacity of the chest. When, on the contrary, we wish to produce a full expiration, the abdominal muscles contract, the viscera are pushed up against the diaphragm, and its convexity towards the thorax is augmented.—(*Bostock's Physiol.*, vol. ii., p. 8.)]

The powers I have thus far noticed, are those which usually act without the interposition of the will, although the will possesses some control over most of them. But whenever this faculty of the mind co-operates and throws its influence into the balance on either side, other powers are sometimes called into action, and the energy of some of these is occasionally suspended. Thus, in the case of a fractured rib, or of pleurisy, the power of the will keeps the ribs quiescent, and the power of expansion is thrown almost entirely upon the diaphragm; while, on the contrary, when, in running, a freer

supply of air becomes necessary, and the heart palpitates from the rapidity with which the blood is thrown into it, the thorax is urged by the stimulus of the will to a quicker respiration, and the muscles that are inserted into the clavicles and scapulæ are often called upon for their conjoint assistance. And where the mind has, from an early period of life, been in the habit of exercising such a control, it is wonderful to contemplate the quantity of air which the lungs may be brought to enclose, and the length of interval through which the life may be preserved without a fresh supply; of which savage nations furnish us with striking examples, in the act of diving and remaining under water. Diemerbroeck relates the case of a pearl-diver who, under his own eye, remained half an hour at a time under water, while pursuing his hunt for pearl-muscles.—(*Anatom.*, lib. ii., p. 464.)

The will also makes use of the muscles of respiration for a variety of other purposes; sometimes for that of freeing the aerial passages themselves, or other cavities connected with them, from some material that irritates or loads them, as in coughing or sneezing, which actions are sonorous from the violence with which the air is protruded. Hiccough, which is a quick, convulsive contraction of the diaphragm, is generally exercised, even without the consent of the will. And sometimes the will employs these powers as mere expressions of mental feeling at the moment, as in laughing, sighing, or weeping; the first of which consists of a mere succession of short and abrupt expirations; and the last two, of deep inspirations, succeeded by deep expirations; broken, in the case of weeping, into a quick series of sonorous snatches; and often accompanied, in sighing, with deep and long-drawn intonations, which we call groans.

[Sir David Barry has endeavoured to demonstrate, that in the ordinary process of respiration, the venous half of the circulating system derives considerable assistance from the action of the atmosphere on the cavity of the thorax. His experiments, as he conceives, establish the two following positions:

1st, That the cavities of the great veins within the thorax, and all the thoracic cavities, draw towards them the fluids with which they are placed in direct communication.

2dly, That this attraction or suction never takes place but during the expansion of the thorax, that is, during inspiration. And, from these facts, he deduces various inferences, among which only the two subsequent ones need here be noticed:

1st, That the blood, *which runs against its own gravity*, arrives at the heart only during inspiration.

2dly, That the power which impels it at this moment through the veins, is atmospheric pressure.*

* Phil. Trans., 1820, p. 29.—On the Elasticity of the Lungs. The above paragraph, marked for insertion in this work, was found among Dr. Good's MSS., subsequently to the publication of the last edition.—Ed.

* See Barry's Exp. Researches on the Influence of Atmospheric Pressure upon the Progression of the Blood in the Veins, &c., 8vo., Lond., 1826, p. 35. The objections made to these views by Drs. Good and Wedemeyer, will be found in the third Physiological Proem of the present edition.—Ed.

The nerves whose influence is principally connected with the function of respiration, are the phrenic and par vagum. If the spinal cord be divided above the origin of the phrenic nerves, respiration suddenly ceases, but the action of the heart remains without any immediate change. If the same nerves be cut through in a living animal, the diaphragm becomes paralytic, and respiration is only imperfectly carried on by means of the muscles which raise and depress the ribs.

When the nervi vagi are divided in the middle of the neck, the breathing is instantly and seriously impeded, and death soon follows. This is supposed to depend upon the paralysis of the muscles, whose function is to open the glottis. In an ass, upon which this experiment had been performed, the breathing became easy as soon as an incision was made in the trachea. From Mr. Brodie's investigations (*Phil. Trans.*, vol. cii., p. 390), it appears, that when the par vagum is divided, the quantity of carbonic acid produced by respiration is lessened. It is curious to learn, from the experiments of Dr. W. Philip, that the difficulty of breathing, caused by the annihilation of the nervous influence of the par vagum, may be temporarily removed by galvanism.]

III. But the most important part of the general economy of respiration consists in the change which takes place in the blood, in consequence of its being acted upon by the inspired air.

We see the blood conveyed to the lungs of a deep purple hue, and deprived of those qualities which fit it for nutrition, secretion, the preservation of the nervous influence, and the maintenance of the vigorous action of every part and organ; or immature and unassimilated to the nature of the system it is about to support, in consequence of its being received fresh from the trunk of the lacteals. We find it return from the lungs spirited with newness of life, perfect in its elaboration, more readily disposed to coagulate, and the dead purple hue transformed into a bright scarlet. What has the blood hereby lost? How has this wonderful change been accomplished?

These are questions which have occupied the attention of physiologists in almost all ages, and were as eagerly studied in the Greek schools as in our own day. To the present hour, however, they have descended in a mantle of Cimmerian darkness; and though the researches of a more accurate chymistry have disclosed volumes of facts heretofore unknown, and the ingenuity of able theorists have laid hold of them, and applied them to an explanation of this curious subject in a great variety of hypotheses, I am afraid we are still almost as much at sea as ever; and that there is no inquiry in the whole range of physiology in a more unsatisfactory state than that concerning the ventilation of the blood in the lungs.

According to a course of well-conducted experiments, instituted many years ago by Sir Humphrey Davy, it appears that the general sum of a man's natural inspirations are about twenty-six or twenty-seven in a minute; and that thir-

teen cubic inches of air are, in every inhalation, taken in, and about twelve and three quarters alternately thrown out. The atmospheric or inspired air was found to contain, in the thirteen cubic inches, nine and a half inches of nitrogen, three and four tenths of oxygen, and one tenth of an inch of carbonic acid; the twelve inches and three quarters of returned air gave nine and three tenths of nitrogen, two and two tenths of oxygen, and one and two tenths of carbonic acid.

[Perhaps, in the foregoing statement, the quickness of ordinary respiration is exaggerated. Laennec says, that the breathing may be considered natural when the number of inspirations in the state of repose is from twelve to fifteen in a minute.* In the latest works on physiology, its frequency is said to vary between fourteen and twenty-seven times in a minute, but the average rate to be from seventeen to twenty.—(See *Mayo's Outlines*, vol. i., p. 87.) In the healthy state of the system, Dr. Bostock (*Physiology*, vol. ii., p. 56) observes, that we respire, upon the average, about twenty times in a minute, while the average velocity of the pulse may be reckoned at eighty; and consequently the heart contracts four times during the completion of each movement of respiration. Laennec's estimate is probably the most correct.]

From the experiments of Sir Humphrey Davy, therefore, there should seem to be a retention in the system of a large portion of the inspired oxygen, and a small portion of the inspired nitrogen; and a discharge from the system of a very considerable portion of carbonic acid gas. And as the colour of the blood is well known to be changed in its passage through the lungs, from a deep modena to a bright scarlet hue, M. Lavoisier, following up with additional facts an earlier set of experiments of Dr. Crawford, endeavoured to show, that while the modena hue is produced by the carbon with which the blood is loaded when it first reaches the lungs, its scarlet results from its losing this surplus of carbon, and acquiring oxygen in its stead; during which process a very large quantity of caloric, or heat, in an elementary form, is supposed also to be disengaged from the air thrown into the air-cells of the lungs, and to pass into the adjoining minute bloodvessels in combination with the oxygen.

[The quantity of oxygen lost by air that has been respired varies considerably, not only in the different kinds of animals, but in different animals of the same species, and even in the same animal at different times, according to the operation of certain external agents, and particular states of the constitution and functions. Under ordinary circumstances, a man consumes on the average about 45,000 cubic inches, or nearly 15,500 grs. of oxygen, in twenty-four hours.†]

* Laennec on Diseases of the Chest, and on Mediate Auscultation, p. 13; transl by Dr. Forbes, ed. 2.

† See Bostock's Physiology, vol. ii., p. 110. Dr. Marshal Hall has inserted in the *Phil. Trans.* some very interesting remarks on the inverse ratio which subsists between respiration and irritability in the

The experiments of Sir Humphrey Davy were afterward repeated by Pepys and Allen; but these acute analysts could not discover that any part of the inhaled nitrogen was retained; since the same exact proportion appeared from their trials to be thrown back in every instance of expiration, as had been previously received in every instance of inspiration. And there have since been doubts on the part of Sir Humphrey Davy himself respecting the supposed caloric; not merely in regard to its separation from the atmospheric air, but as to its substantive existence at all, either there or elsewhere, heat being, in his later view of the subject, nothing more than a rapid, vibratory, or repulsive action of the corpuscles of a body that exhibits this phenomenon: thus reviving the doctrine of Aristotle and the Peripatetics, which was so ably controverted by the Epicureans, who, forestasting the spirit of the Lavoisierian system, strenuously contended that it was a substance *sui generis*.* While, to close the whole, Mr. Ellis has gone through another extensive range of inquiry, and instituted another numerous set of experiments, to prove that even the oxygen of the inspired air does not enter into the bloodvessels of the lungs, but becomes itself converted in the air-cells of these organs into the carbonic acid gas of the expired air, by uniting with the carbon of the blood, which he supposes, as acrement, to be secreted in the form of a vapour into the air-cells, by the exhalants of the lungs.† He admits, however, the existence of caloric as an elementary principle; conceives it to be disengaged in very large abundance from the inspired

air during its union with the secreted carbonic halitus; and ascribes the recovered scarlet hue of the blood to its combination with this invisible fluid; as he does also whatever effects are produced by the exercise of the respiratory function, not merely in animals, but in plants.

Of the facts and arguments in favour of Mr. Ellis's hypothesis, which he extends to plants as well as to animals, the two following seem to be the chief. Firstly, the seeds of plants in germination, and plants themselves in growth, throw forth carbon in the form of aqueous vapour, or, in other words, dissolved in water, even where no oxygen is present.—(Op. cit., 8vo., 1807, sect. 20.) And, secondly, such ejected fluid, wherever life exists, is the work of secretion. In consequence of which, he ventures to affirm that it is a secretion of this kind which is continually taking place on the surface of the lungs and of the skin in animals, both which, he thinks, concur in a common action; and in support of this opinion, he refers to various insects and worms, without stigmata or stemmata, which appear to breathe by the pores of the skin alone.

According to Mr. Ellis, we have no proof of carbonic acid, or of any æriform fluid existing naturally in the blood (Op. cit., sect. 98, p. 122), and consequently have no reason to expect that any can be thrown out: while, if oxygen enter from the air-cells into the system, it must be by absorption or chymical affinity. If by absorption it would in animals take the regular course of the thoracic duct, and the blood in the right ventricle of the heart would first exhibit a scarlet hue; while, in the germination of vegetables, their seeds give no evidence of possessing a structure fitted to absorb and expel æriform fluids; nor of any such fluids at any time existing in them.—(Op. cit., sect. 16, p. 18.) To the operation of chymical affinity, he conceives an actual contact between the air and the blood to be requisite; but in the lungs we have an intervention of the coats of the cells, and of the bloodvessels. And if these be presumed so thin, that, when moist, they will allow the air or its oxygen gas to pervade them, the gas would rather pass into the interstices of the cellular substance than into the pulmonary vessels, and thus create an emphysema. But the whole of such permeation he holds to be gratuitous, and contrary to experiment.—(Op. cit., sect. 101, p. 125.) The diminution in the bulk of respired air (calculated by Dr. Bostock to be on the average about one eightieth of its bulk), (*Physiol.*, vol. ii., p. 112), he thinks, may be accounted for by a union of the carbon of the blood with the oxygen in the air-cells, and the formation of aqueous vapour by the disengagement of the caloric from the oxygen of the atmospheric air.—(Op. cit., sect. 83, p. 99; sect. 107, p. 132; and compare with sect. 11, p. 13.)

To these objections, however, it may be replied, that if caloric can penetrate animal membranes, and unite by chymical affinity with the blood in the bloodvessels, so, for any thing we know to the contrary, may oxygen. [Dr. Davy found, that in certain morbid conditions of the

animal kingdom. He endeavours to prove that the quantity of respiration is inversely as the degree of the irritability of the muscular fibre; or, in other terms, that in cases in which the quantity of respiration is great, the degree of irritability is low. By the quantity of respiration is signified the quantity of oxygen gas consumed or exchanged for carbonic acid in a given time, by the animal placed in atmospheric air. Dr. Hall regards that muscle as the most irritable which, *cæteris paribus*, contracts most, and for the longest time, upon the application of the least degree of stimulus. According to his researches, respiration in the bird tribes and the mammalia is great, while the irritability of the muscular fibre is low. On the contrary, the reptiles, the batrachia, and the fish tribes are endued with a high degree of irritability, but possess only an inferior quantity of respiration. As Dr. Hall observes, the quantity of respiration is greater in proportion as the animal occupies a higher station in the zoological scale, being among the vertebrated animals greatest of all in birds, and lowest in fishes: the mammalia, the reptiles, and the amphibia, occupy intermediate stations. The quantity of respiration is also remarkably low in the very young of certain birds, which are hatched without feathers; and of certain animals which are born blind; and in hybernation it is almost extinct. Dr. Marshal Hall's paper is exceedingly valuable, and his contrivance for measuring the quantity of respiration with minuteness particularly ingenious: it is named the *pneumatometer*.—Ed.

* See the Author's Translation of Lucretius.

† Inquiry into the Changes induced on Atmospheric Air, 8vo., 1807.

VOL. I.—Q

chest, the pleuræ had the power of absorbing, and probably of exhaling air; and such absorption extended likewise to air purposely introduced between these membranes in their healthy state. Hence he inferred that mucous membranes may generally possess the power of absorbing and exhaling air; and that these operations naturally belong to the process of respiration.—(*Phil. Trans.*, 1823, p. 496.)] Mr. Porrett has shown, that the voltaic fluid, when operating upon water, is capable of carrying even water itself through the bladder, and raising it into a heap against the force of gravitation.—(*Thomson's Annals of Philosophy*, No. 43, p. 75, 76.) A like combination may take place between the voltaic or some similar fluid and the oxygen, and a part of the nitrogen gases in the air-cells of the lungs; and a similar permeation may follow directly through the membranes of the bloodvessels; and the carbon of the system may in consequence pass off by the same channel, instead of being secreted: and in the form of carbonic acid, instead of in that of carbonic vapour.

Next, we have no proof that carbon will dissolve in water, and produce such vapour; and hence, at present, this idea is gratuitous.

Again, air appears, in various cases, to have been actually disengaged, and is, perhaps, perpetually disengaging from the blood. Mr. J. Hunter declares he has discovered it in an abscess, in which it could neither have been derived from without nor from putrefaction (*Animal Economy*, p. 207); and he hence adopted the opinion that air is often secreted by animal organs, or separated from the juices conveyed to them.* And this opinion has not only been abundantly confirmed, but even extended to the vegetable world since his time; for Mr. Bauer appears to have shown, that an elastic gas is constantly shooting forth in small bubbles from the roots of plants into the slimy papulæ by which they are surrounded; and that it is hence the slimy matter becomes elongated, and is rendered vascular, or converted into hair or down. And Mr. Brande instituted experiments tending to prove that carbonic acid does exist, and that, too, in a considerable quantity, in the blood of animals, while circulating through both arteries and veins; and that it is so largely poured forth from blood placed, while warm, under the receiver of an air-pump, as to give the appearance of effervescence; a fact familiar to Mr. Boyle nearly two centuries ago. The venous and arterial blood, according to Mr. Brande's experiments, seems to contain an equal proportion of this gas; and he calculated that not less than two cubic inches were extricated from every ounce of blood thus experimented upon. And hence Sir Everard Home, following up the discoveries of Mr. Bauer, ingeniously conjectures that it is by the escape of bubbles of this gas from the serum of blood, in cases of effusion and coagulation, that new vessels are formed;

* See various facts in confirmation of this view in Dr. Davy's "Observations and Experiments on Air found in the Pleura," &c.—*Phil. Trans.*, 1823, p. 496.

as also granulations in pus, as a like gas appears to be separable from this latter fluid.—(*Phil. Trans.* for 1818, p. 180.)

[Dr. John Davy arrived, however, at a conclusion entirely different from that of Mr. Brande, namely, that no free carbonic acid exists in the blood. In the spontaneous coagulation of this fluid, and in that of the serum by heat, he never observed carbonic acid to be disengaged; nor has he been able to procure carbonic acid gas from blood just taken from the vessels, still warm, and placed under a receiver, and completely exhausted of air. He states that he has raised the temperature of the blood and serum to blood-heat, and coagulated both by a heat of 200° Fahrenheit, without a particle of gas being extricated.—(See *Edin. Med. and Surg. Journ.*, No. 95.) This discrepancy between philosophers of such eminence seems to demand a careful repetition of their experiments by others.]

After what has been stated, the observations of Mr. Ellis are by no means sufficient to subvert the Lavoisierian hypothesis of respiration. And some late experiments, both of Gay Lussac and of Magendie, tend to support those of Sir Humphrey Davy, since they concur in proving that, in the act of respiration, there is a little more carbonic acid gas than oxygen consumed.

Since the first edition of this work was printed, the objections here offered to Mr. Ellis's conclusion, and the support thus attempted to be given to M. Lavoisier's hypothesis, have been amply and very plausibly supported by a new set of experiments, conducted with the utmost accuracy, and upon a far more extensive scale than ever, by Dr. Edwards of Paris, who is fairly entitled to be regarded as one of the clearest and ablest physiologists of the present day. [The doctrine, that the essential part of respiration is the union of the carbon of the blood with the oxygen of the atmospheric air, and the consequent formation of carbonic acid, implies that the carbonic acid produced in breathing is precisely equal to the volume of oxygen lost. Although this was maintained to be the fact by Allen, Pepys, Ellis, Magendie, and others, the experiments of Dr. Edwards may be considered as a decided refutation of the theory. According to this eminent physiologist, the excess of oxygen consumed in respiration, above the volume of carbonic acid gas produced, varies from nearly one third of the oxygen that disappears to almost nothing. The variation depends upon the species of the animal employed; upon its age, peculiarity of constitution, and condition at different periods.* Hence a different theory of respiration. Part of the oxygen that disappears may be absorbed in the lungs, and the remainder may either combine with the carbon of the blood, and form carbonic acid, or the whole of the oxygen may be absorbed, and the expired carbonic acid be a new secretion. The latter hypothesis is espoused by Dr. Edwards. When,

* *De l'Influence des Agens Physiques sur la Vie*, &c., p. 418. Paris, 1824, 8vo.

in the month of March, frogs are immersed in pure hydrogen for eight hours, after all the air in their lungs has been pressed out, they continue to breathe, though less and less vigorously, and emit carbonic acid. The same fact was observed in kittens subjected to a similar experiment. A doubt has been suggested whether the carbonic acid came from the lungs, because it is exhaled when frogs are placed in hydrogen in the summer months, and breathe rarely, or not at all. It is also argued that, even supposing the carbonic acid were derived from the lungs in these experiments, it may not be exhaled by the lungs in the natural state of respiration. On the whole, however, Dr. Edwards's views must be allowed to rest on facts, not readily admitting of any other interpretation than what he has given them.] The experiments of the same distinguished physiologist also prove, that nitrogen gas is exhaled, and likewise absorbed. The carbonic acid is sometimes equivalent to the oxygen which disappears, but sometimes also it is less; and the nitrogen gas exhaled is sometimes inferior, sometimes equal, and sometimes superior, to the quantity absorbed.

The quantity of air inhaled in a single act of inspiration, is found to vary in persons of different-sized chests; but the aggregate inhaled in a given period, does not essentially differ; since those who inhale most at a time make the fewest inspirations in a minute. I have said that Sir Humphrey Davy calculated the average number of respirations in a minute at twenty-six or twenty-seven, and that the measure of air inspired or expired was estimated at about thirteen cubic inches each time. This breathing has since been supposed too rapid for a common standard, and the measure of air received and returned too low; but, as the former error compensates the latter, the amount of air does not essentially deviate from the general allowance for a minute. And it is by this explanation alone that we can in any way reconcile the different results which have been given by different experimenters upon this subject. Dr. Godwin calculated the inspired air at twelve cubic inches, and the expired at fourteen, being a difference produced by expansion from the heat of the lungs (*Connexion of Life with Respiration*, pp. 27, 37); which does not essentially vary from the above estimate of Sir Humphrey Davy; and he calculated the residuary air in the lungs, immediately after expiration, at one hundred and nine cubic inches, which, upon inspiration, was increased to one hundred and twenty-three. But Borelli states the inspired air at from fifteen to twenty cubic inches (*De Motu Animal.*, p. 126); while Jurin, Haller, and Menzies give that which is expired at not less than forty.—(*De Respirat.*, p. 32.)

In good health, perfect quiet, with an open chest, few persons, perhaps, are found to breathe more frequently than about twenty times in a minute; and the quantity inhaled and exhaled, at a temperature of fifty-five of Fahrenheit, is estimated at from twenty-six to thirty-two cubic inches each time; which, however, by the heat

of the lungs, and saturated with moisture, become forty or forty-one cubic inches in the chest itself. Taking, then, twenty cubic inches as the ordinary quantity of external air inhaled and exhaled about twenty times in a minute, it will follow that a full-grown person respires twenty-four thousand cubic inches in an hour; or five hundred and seventy-six thousand cubic inches in the course of a day; a total equal to about thirty-nine hogsheads.

The quantity of carbon thrown out of the system of the lungs, when estimated in the gross, may afford matter of no less astonishment. For, taking the gravity of the carbonic acid gas as calculated by Lavoisier, a person in health must emit from his lungs something more than is equal to twelve ounces of solid carbon, or charcoal, every twenty-four hours; or, according to another estimate, five thousand two hundred and eight grains.—(*Bostock's Physiol.*, vol. ii., p. 111.)

The primary cause of the red colour of the blood is a chymical, rather than a physiological question: and belongs to the sanguiferous, rather than to the respiratory function; yet, upon this point also, physiologists are by no means agreed, some ascribing it to the conversion of the iron, which forms a constituent principle of the blood, into a red oxide; and others, and particularly Sir Humphrey Davy, to the affinity which the calorific rays of light have for oxygen generally, and hence, for the oxygen of the animal system; against the surface of which it is perpetually impinging, and into which it is perpetually carried in combination with the inspired air; separating it incessantly from its union with the carbon of the animal frame, and transforming the carbon, thus decomposed and simplified, into a dark pigment. But there are difficulties that hang about both these, and, indeed, every other hypothesis that has yet been started, concerning even the primary cause of the red colour of the blood, as we shall have occasion to notice more at large hereafter.

Yet, whatever may be the primary cause of the red colour of the blood, we find that, in respiration, there is some other cause superadded, and which, as observed above, heightens the colour the blood possesses at the time of its reaching the lungs, and converts it from a deep purple, or modena, into a rich scarlet. This M. Lavoisier, as we have already hinted, supposed to be produced by that supply of oxygen which he conceived it was the express object of respiration to communicate to the blood; and in support of this view, a variety of experiments were appealed to, which seemed to show that the colour of the blood becomes brighter whenever exposed to the action of oxygen. Yet, till all the objections of Mr. Ellis are satisfactorily removed, and those of Dr. Edwards are further confirmed, that oxygen in a free state is actually introduced from the aircells of the lungs into the adjoining minute bloodvessels, we can place little dependance upon this explanation, however plausible and inviting.

But, may not the deepened colour of the

blood be produced by the carbon, with which it becomes gradually loaded in the course of its circulation, and which, by the consent of all parties, is separated from it in the process of respiration? and, consequently, may it not recover its brightness by the mere loss of this dingy pigment, whether oxygen enter at the same time into the bloodvessels or not? If the primary colouring material of the blood be the iron which it contains, as first suggested by MM. Parmentier and Deyeux, and the carbon be a crementory and adventitious material, this reply might be satisfactory; but if, as supposed by Sir Humphrey Davy, the carbon of the blood be itself the pigment that colours it from the first, the explanation will content but very few. Yet this last hypothesis is as open to attack as any of the rest; for, to say nothing of the difficulty of conceiving how the carbon of the animal fluids can give a deep die to the blood, while it gives no die whatever to any of the fluids besides, it is sufficient to observe, that an abstraction of a part of this die may, indeed, form a lighter hue of the same kind, but not a different hue. The hypothesis has yet to account for that yellow or orange tint, which must be added to the red venous blood before it can become changed into the red of the arterial; for, as a simple dilution of venous blood will not furnish this tint, so neither will a simple abstraction of the only colouring material which is hereby supposed.*

[In the consideration of the cause of the loss of the bright scarlet colour, one fact, pointed out by Mr. Hunter, merits particular notice, viz., that blood, when it is rendered stagnant in an artery by the effect of a ligature or the tourniquet, or in the cellular membrane by extravasation, assumes the purple colour of venous blood.—(*On the Blood*, p. 65.) But, as Dr. Bostock properly remarks, even if Hunter's experiments, and certain others undertaken by Hassenfratz, were to be received as proofs that the change of blood from the arterial to the venous state may be effected independently of any addition from without, it does not necessarily follow that the reverse operation can happen in the same manner; nor, indeed, have we any evidence that it ever has been accomplished, without the intervention of oxygen.—(*Physiol.*, vol. ii., p. 133.)]

It may perhaps be said, that though oxygen do not get admission, caloric does; and this, too, very freely, and becomes itself the cause

of this change of colour. And, in truth, this is the explanation offered by Mr. Ellis and various other physiologists; who contend that the function of respiration consists, firstly, in freeing the blood from its load of carbon, and, secondly, in introducing a very large portion of the matter of heat in its stead; thus far advocating the hypothesis of Dr. Crawford. And as a proof that caloric, as a substance, is separated from the inspired air, they appeal to the quantity of vapour that is formed in the vesicles of the lungs simultaneously with a formation of the carbonic acid, and which they ascribe to this cause: regarding the lungs as the great laboratory, in which the matter of heat or caloric is accumulated, and rendered fit for the use of the system.

But this again is to take for granted what yet remains an unsettled question, namely, whether caloric be a substance or a mere quality of body. Independently of which, admitting the substantive existence of caloric, and that some organ or other is specially employed in its evolution and introduction in a free state into the system, it is by no means established that this organ is the lungs; for Dr. Currie, in an ingenious paper published some years ago, attempted to show, by various experiments, that this is chiefly effected by the action of the stomach, which was also the doctrine of Mr. Hunter. And Mr. Brodie has long since brought other experiments that seem to refer it to the action of the brain.—(*Phil. Trans.*, 1812, p. 378.) Perhaps, however, all these, and various other organs, may co-operate to the same effect.

Much still remains to be ascertained upon this interesting subject. Even the recovery of the bright hue itself to the blood, by whatever means accomplished, and which by most physiologists is regarded as a fact of the utmost importance in the process of respiration, is contemplated by Mr. John Hunter as of scarcely any importance whatever, except as a proof that the blood has undergone the action of ventilation; an action which he conceives, from its being as necessary to white-blooded animals as to red-blooded, produces a far greater effect on the coagulating lymph than on the red particles.—(*On Blood*, pp. 204–206, &c.) And hence, though we have an abundance of facts and experiments upon the subject before us, and an abundance of speculation in respect to them, “the COMMERCIUM MENTIS ET RERUM,” as Lord Bacon has elegantly expressed it, has not hitherto led to any established doctrine, however creditable it has been to the industry and ingenuity of those who have engaged in it.

* Some Observations on this subject, by Dr. Stevens and Mr. Hoffmann, will be referred to in the next Physiological Proem.—Ed.

CLASS II.

PNEUMATICA.

ORDER I.

PHONICA.

AFFECTING THE VOCAL AVENUES.

THE term PHONICA (ΦΩΝΙΚΑ) is sufficiently explained in the definition. The order of diseases which it is intended to comprehend, are seldom dangerous or acutely painful; and are rather characterized by trenching upon the grace or utility of the voice, than undermining the general health. It embraces the following

GENERA.

I. Coryza	Running at the Nose.
II. Polypus.	Polypus.
III. Rhonchus.	Rattling at the Throat.
IV. Aphonia.	Speechlessness.
V. Dysphonia.	Dissonant Voice.
VI. Psellismus.	Dissonant Speech.

GENUS I.

CORYZA

RUNNING AT THE NOSE.

DEFUXION FROM THE NOSTRILS OBSTRUCTING THEIR CHANNEL.

IN the commentary to the nosological text, I have ventured to point out what seems to be the real origin of the term coryza, concerning which the Greek lexicographers are at a loss; and have shown it to be a genuine and very extensive as well as very ancient oriental term, common, under some modification or other, to the Hebrew, Arabic, Chaldee, and Syriac dialects, from one of which it was doubtless imported into the Greek tongue. By Hippocrates it was used in a very extensive sense, so as to signify defluxion of any kind, whether from the head, nostrils, fauces, or chest. The later Greek physicians restrained coryza to a defluxion from the head and nostrils, and applied the term catastagnus to a defluxion from the fauces and thorax. Among modern writers, at least since the time of Cullen, coryza is used synonymously with catarrh, and is consequently regarded as a febrile affection. But this is rather to confound morbid affections than to simplify them. Coryza, running, defluxion or distillation from the nose, may indeed occur as a symptom in catarrh, as it may also in various other complaints, as the measles, and some species of ophthalmia; but it may also occur, and as a simple and idiopathic affection does occur, without febrile action of any kind. In which cases, indeed, it is of little importance, and not often worthy of medical interposition: yet, in a general system of morbid affections, it ought no more to be passed by unnoticed, than a hedge or bog plant in a system of botany.

Simple defluxion from the nostrils may proceed from two very different states of body, or of local power in the organs affected; which

furnish us with two distinct species of affection, characterized by sufficiently marked and discrepant symptoms:—

- | | |
|---------------------|-----------------|
| 1. Coryza Entonica. | Entonic Coryza. |
| 2. Coryza Atonica. | Atonic Coryza. |

SPECIES I.

CORYZA ENTONICA.

ENTONIC CORYZA.

THE DEFUXION PELLUCID, MUCOUS, OR ROPY; WITH A SENSE OF IRRITATION OR INFARCTION.

IN this species there will always be found an increased action of the secretory emunctories of the nostrils, while the absorbents remain little disturbed in their function; and as a morbid diminution of active power is ordinarily expressed by the terms atony, and atonic, so ctony and entonic are in the present work employed to express the opposite, or a morbid excess of activity. According to the difference of the stimuli or accidental causes, by which the present affection is produced, there will be some difference in the symptoms: for these causes may be, sternutatories; the irritation of continuous sympathy, as in crying or weeping; a damp chill, or some other change produced suddenly in the temperature, or perhaps temperament, of the atmosphere. And it is still more generally, and often with great abruptness, brought on by a transfer of action, or a sort of reverse sympathy with some remote organ. Thus, there are many persons, who, as Dr. Darwin observes (*Zoonom.*, Cl. I., Ord. I., ii. 7), by sleeping at night with their arms or shoulders accidentally uncovered, become cold and torpid in the cutaneous vessels of these organs, and have their nostrils instantly affected with increased action, filled with mucus, and so thickened in the mucous membrane, as to render them almost incapable of breathing.

An ozæna or nasal ulcer will also frequently produce a like effect; in which case the increased defluxion will be intermixed with a purulent or ichorous matter, sometimes throwing forth an offensive smell: all which may be arranged in a tabular form under the following varieties:—

- | | |
|------------------|--|
| α Sternutatoria. | From sternutatories: accompanied with sneezing. |
| β Lachrymosa. | From weeping or crying: the lachrymal secretion being increased by mental emotion. |
| γ Catarrhalis. | From sudden chill or moisture in the temperature or temperament of the atmosphere. |
| δ Ozænosa. | The defluxion more or less purulent; or ichorous and fetid. |

The last is a case of surgical rather than of medical treatment, and is often connected with a caries of the ossa spongiosa, or ossa nasi, and frequently with a lodgment of pus in the frontal sinus or antrum maxillare; in both which cases the inflammation is at times accompanied with excruciating pain. The first is peculiarly common to grazing animals, and especially to sheep, from the irritation of minute insects, and especially those of the gadfly, whose eggs have been deposited in the upper part of the nostrils by the impregnated female.

From the dryness of the mucous membrane of the nostrils in India, the common coryza is peculiarly frequent under the name of *naukera*. The natives cure it in its onset by topical bleeding; for which purpose they prick the inflamed membrane with a sharp-edged grass, which answers the purpose of a lancet, and soon relieves the pain by the flow of blood which ensues.*

A warm atmosphere easily, and in a short time, takes off the variety produced by a sudden application of cold, or a sudden change in the temperament of the atmosphere, and which makes an approach towards a catarrh, though without any sense of heaviness or oppression in the head, or harshness in the fauces. From the obstruction of the nostrils, however, there is usually a nasal voice and a deficiency or loss of smell; and, where the discharge is acrid, an excoriation of the mucous or Schneiderian membrane. When it is the result of a reverse sympathy with the arms or other limbs, rendered chilly at night by being uncovered, it is easily and almost instantly removed by covering the chilly organs with additional bedclothes, and thus restoring the balance of heat and cutaneous secretion.

In a singular idiosyncrasy, reported in the *Ephemeræ of Natural Curiosities*, the odour of roses, without amounting to a sternutatory, proved a stimulus sufficient to excite a coryza whenever applied.—(Dec. ii., ann. v., obs. 22.) It is well remarked by Galen, that various foods produce a like effect (*Fragment ex Aphor. Rabi Moyses*, p. 36); and Bonet, in one instance, found it occasioned by a globular tumour, surrounded by a fluid in the ventricles of the brain (*Sepulchr.*, lib. i., sect. xvii., obs. 10), probably from an excitement of the olfactory nerves, which take their rise in the corpora striata, situated in this quarter of the cerebrum.

SPECIES II.

CORYZA ATONICA.

ATONIC CORYZA.

THE DEFUXION LIMPID, AND WITHOUT ACRIMONY OR SENSE OF IRRITATION.

THE chief causes are, exposure to a keen frosty air; the natural paresis of old age; and a long and immoderate use of strong aromatics, volatile alkali, or snuff; affording the three following varieties:—

* Miscellaneous Obs. on certain Indigenous Customs, &c., in India, by Daniel Johnson.

α Algida.

From exposure to a keen frosty air.

β Senilis.

From old age.

γ Superacta.

From habitual indulgence in snuff, or nasal stimulants.

In all these there is diminished action in both the secretory and absorbent vessels of the nostrils, but chiefly in the latter, which almost uniformly yield soonest, from causes we shall hereafter have to explain. And hence, while the secretions are only capable of separating a thin limpid water, instead of a viscid mucus, the absorbents are too inert to carry off even this, which in consequence accumulates, and drips from the nostrils. A warm atmosphere, or the vapour of warm water snuffed up the nostrils, affords an easy remedy for the first variety of this species, which far more frequently occurs, and perhaps only occurs, in a dry, sharp, frosty air, than in an atmosphere rendered chilly from damp; damp being, as already noticed, rather a cause of the preceding species. In the former case, the severity of the cold overcomes all power of reaction; and hence, notwithstanding there is a defluxion, because whatever is secreted is not carried off by the correspondent absorbents, the discharge is checked in its quantity, at the same time that it is rendered more limpid. In the latter case the tone of the excretories rises superior to the chill to which they are exposed, and the reaction ascends to something of a morbid excess. A warm room, and particularly the excitement of a gentle perspiration, will cure both; but the first is also often cured by brisk walking, or any other vigorous exercise proportioned to the sharpness of the frost; for as the system becomes roused generally, the nasal excretories become roused also, and triumph over the cold with a reactive power, which is at the same time communicated to the correspondent absorbents, when the defluxion immediately ceases.

The last two varieties are beyond the reach of medical aid. The coryza, or snuffing of old age, is precisely analogous to its ptyalism or drivelling. In the one the atony is seated in the excretories of the salivary glands; in the other, in those of the mucous membrane of the nostrils. Among the habitual irritants that lead to the same effect, snuffs are the worst; for the tobacco of which they consist operates with the mischief of a narcotic as well as of a stimulant; and hence the copious and foul secretion with which the nostrils of aged snuff-takers are constantly deformed.

GENUS II.

POLYPUS.

POLYPUS.

FLESHY, ELONGATED EXCRESCENCE, GENERALLY SHOOTING FROM A COMPARATIVELY SLENDER ROOT ATTACHED TO SOME PART OF THE MUCOUS MEMBRANE OF THE NOSTRILS; EXTENDING IN DIFFERENT DIRECTIONS, AND AFFECTING THE SPEECH.

This is the polypus, properly so called, and

the disease to which the term is applied by Celsus, and continued to be applied till after the days of Heister, who uses it in the same restricted sense. More lately, however, the term polypus has been employed in a much looser signification, and made to import concretions and excrescences appearing in various channels or cavities of the body, of very different origins and textures, as those of the heart; those of the uterus and bladder, which are caruncles or sarcophytes, with a slender base or peduncle; and those of the trachea in croup, which are concrete gluten; whence the croup is by such writers denominated *angina polypus* or *polyposa*.

It is better, with the old authors, to restrain polypus, as a distinct generic term, to peduncular excrescences in the nostrils, and to distinguish by the phrase polypous tumours, caruncles, or shoots, such adscititious productions as may have a resemblance to them in other organs.*

Polypus, in the above limited sense, comprises two species, from the very different texture under which it is found.

1. Polypus Elasticus. Compressible Polypus.
2. ———. Coriaceous. Cartilaginous Polypus.

SPECIES I.

POLYPUS ELASTICUS.

COMPRESSIBLE POLYPUS.

SOFT, COMPRESSIBLE, UNACHING, CHIEFLY PALE-RED; APPARENTLY ORIGINATING FROM DISTENTION OR RELAXATION OF THE SCHNEIDERIAN MEMBRANE.

This species is very apt to be affected by the state of the atmosphere; being often retracted and shrivelled in dry weather, and enormously enlarged and elongated in thick, hazy weather. There is little pain during any stage of its progress, however troublesome it may be to deglutition or the voice. [The most common variety of the compressible polypus is that which bears, in consistence, shape, colour, and size, a striking similitude to the common oyster.—(See *Gibson's Surgery*, vol. ii., p. 296. Philadelphia, 1825.)] If attended to when small, or in an incipient state, it may often be prevented from growing large by the use of astringent applications; as a strong solution of alum, a decoction of oak-bark, or the application of vinegar or brandy. But where the excrescence becomes inconvenient from its bulk, it ought to be instantly extirpated. When timely attendance is not paid to it, and especially in unhealthy habits, it sometimes assumes a scirrhus character, and at length is apt to bleed with great freedom, sloughs, and ultimately produces, from its increased size and malignity, a horrible disfigurement of the face, and renders life most pitably distressing. And where it does not become strictly cancerous, it degenerates into a

fungous ulceration, nearly as much to be dreaded.*

[Experience proves that extraction with a suitable kind of forceps, is generally the best method of extirpating nasal polypi. In a very few instances other plans are allowable. Thus, in one case, under the care of Mr. Robertson, of Kelso, the size of the polypus rendered the introduction of a pair of forceps, or a ligature, impracticable. Hence, an incision was made through the nose on the affected side, and the mass of the polypus brought into view. Two ligatures were passed through it; but its magnitude was such that its root could not be reached. By perseverance, however, so much of the tumour was cut away, with the aid of the ligature, that Mr. Robertson at length succeeded in detaching the root with the point of his finger.†]

SPECIES II.

POLYPUS CORIACEUS.

CARTILAGINOUS POLYPUS.

FIRM, CARTILAGINOUS, OFTEN PAINFUL, CHIEFLY DEEP-RED: APPARENTLY ORIGINATING FROM, OR CONNECTED WITH, CARIES OF THE ETHMOID BONE.

This species is not only painful, but, from being firm and deep-seated, very troublesome in removal. It is not always, indeed, that it can be extirpated entire, or that it is advisable to extirpate it when possible. When extracted imperfectly, it is very apt to regenerate, and has sometimes become cancerous.

It is too generally believed, however, that polypi in all instances may and ought to be extracted; and that, if the shoot can be laid hold of by the forceps, and we are not afraid of any hemorrhage, nothing is to be dreaded from the operation. Mr. Pott was of a different opinion: he had observed many cases, which, though neither scirrhus nor cancerous, were very unfit for any surgical process. Some circumstances, he remarks, may forbid the attempt, from the impossibility of its being successful; others, from its being more likely to increase and exasperate the disease than to cure it. He dissuades from the operation in almost every instance of the second or coriaceous species; in all those cases in which the polypus begins with considerable pain in the forehead and upper part of the nose, or is preceded by these symptoms; and which, as soon as it can be seen, is either highly red, or of a dark colour; which is never alternately smaller and larger, but rather progres-

* Lectures of Sir Astley Cooper, Bart., with additional notes, &c., by F. Tyrrell, Esq., vol. i., p. 354, 355, 8vo., 1825. Whether the soft compressible polypus, originally of a benign character, ever becomes one partaking of a cancerous nature, or rather of the character of fungus hæmatodes, may be doubted.—Ed.

† Edin. Med. Journ., No. 90, p. 44. Graefe has invented some most ingenious contrivances for trying polypi in the nostrils, as well as other situations. These instruments are constructed and sold by Mr. Weiss, of the Strand.—Ed.

* Polypi are now regarded as growths peculiar to mucous membranes, or surfaces; and as these exist in various parts of the body, so must polypi also present themselves in different situations.—Ed.

sively increasing; in which the common actions of coughing, sneezing, or blowing the nose, give pain, or produce a very disagreeable sensation in the nostril and forehead; in all cases of polypi, which, when within reach, are painful to the touch, or which, upon being touched slightly, are apt to bleed; those which do not seem to be moveable by the action of blowing the nose, or driving the air through the affected nostril only, when confined to one side; those which are incompressibly hard, and, when pressed, occasion pain in the corner of the eye, or in the forehead, and which, if they discharge any thing, shed blood; those which, by adhesion, occupy a very considerable space, and seem to consist of a thickening or an enlargement of the membrane covering the septum narium; those from which there is a discharge of an ulcerous, offensive, discoloured fluid; and those round the lower part of which, within the nose, a probe cannot easily and freely be passed to some height. In all cases thus characterized, Mr. Pott was of opinion, that no trial should be made by the forceps; and he advised further, that no attempt to remove them should be made by any other means, with which he had the good fortune to be acquainted.*

But where these characters do not occur, and, in general, where the polypus answers to the first species in elasticity and colour, he recommends its removal, and by the forceps rather than by escharotics, ligature, or any other means; and thinks it may be extracted with great safety.†

GENUS III.

RHONCHUS.

RATTLING IN THE THROAT.

HAIRSH, SONOROUS BREATHING FROM STAGNATION OF MUCUS IN THE VOCAL CANAL.

THERE are two species of morbid affection which may be arranged under this genus, each of which has been raised to the rank of a distinct genus by Vogel and several other nosologists; while by Cullen, and those who have followed him, they have been entirely struck out of the catalogue of morbid affections, as either unworthy of notice, or merely symptomatic of some other complaint.

To a generic distinction they are scarcely entitled; but a slight acquaintance with the habits and morbid actions of the system is sufficient to afford instances in which both sorts

are idiopathic. Many persons have a thick or wheezy respiration, produced by corpulency, or by changes of the atmosphere, from hot to cold, or from dry to moist, without any other disease. Many persons snore habitually during sleep; and most persons have a tendency to do so as they grow old. Under such circumstances, the affections before us are strictly idiopathic. They are not often indeed accompanied with much inconvenience; but, as deviations from a perfect state of health, they have a full claim to their respective places in a general system of nosology. Confervas in botany, and infusory worms in natural history, are as confessedly objects of scientific arrangement and study, as the oak and the elephant.

The two species, then, appertaining to the present genus, are the following:—

1. Rhonchus Stertor. Snoring
2. ————— Cerchnus. Wheezing.

M. Laennec has increased the subdivisions of rhonchus, or, as he calls it, *râle*, to five; and as modified by a variety of primary diseases of the chest, they may easily be extended to this number; but then they become mere symptoms, and not idiopathic affections. "For want," says he, "of a better, or more generic term, I use the word *râle*, *rattle*, or *rhonchus*, to express all the sounds, besides those of health, which the act of respiration occasions, by the passage of the air through fluids in the bronchiæ, or lungs, or by its transmission through any of the air-passages partially contracted." He distinguishes five principal kinds of rattle:—1. The moist crepitous. 2. The mucous, or gurgling. 3. The dry sonorous. 4. The dry sibilous, or hissing. 5. The dry crepitous, with large bubbles, or crackling.*

SPECIES I.

RHONCHUS STERTOR.

SNORING.

THE SOUND DEEP AND LOUD; PRODUCED IN THE LARYNX AND FAUCES.

As a symptom, this is common to apoplexy; but, as I have just observed, it is found idiopathically in many instances, brought on by advancing age, or peculiar to the habit. A syrup, made of the leaves of the *erysimum officinale*, or hedge-mustard, was for this kind of noisy breathing once popular; and the pungency of the plant may often prove useful. The common cause is here, a lodgment of the tougher and denser part of the mucous secretion of the larynx and fauces in these passages.

In some cases, as in the atonic coriza of age, the excretories of these organs may be permanently relaxed, so as to admit of a larger defluxion than in health and vigour. And hence, local stimulants are particularly applicable; among the best of which may be ranked cam-

* This form of polypus is termed by Prof. Mott, the chondromatous; it is often attached to the inferior turbinated bones. Dr. Mott recommends for its cure, the removal of the turbinated bone with which it is connected, which may be done without inconvenience.—D.

† *Chirurgical Obs. relative to the Cataract, Polypus of the Nose, &c., 8vo., Lond., 1774.* The most common malignant polypus of the nose, is now generally believed to be of the nature of fungus hæmatodes, or medullary sarcoma, to which the surgeon cannot usefully apply any operation in this situation. Palliative treatment is all that can be adopted.—E.

* *De l'Auscultation Médiate, ou Traité du Diagnostique des Maladies des Poumons et du Cœur, &c., par R. T. H. Laennec, &c., 2 tomes, Paris, 1819; and translation, with Notes, by Dr. Forbes, 2d edit., p. 49.*

phire, and other terebinthinate medicines, gum ammonia, and the alliacea.

SPECIES II.
RHONCHUS CERCHUS.
WHEEZING.

THE SOUND DENSE AND IMPEDED; PRODUCED
BELOW THE LARYNX.

This affection, as a symptom, is common to asthma and dyspnœa; but, as I have already observed, it is sometimes found as a primary evil, or independent of any other complaint. In the introductory dissertation to the present class we remarked, that a considerable quantity of aqueous vapour is formed in the air-cells of the lungs during the process of respiration; supposed, by the physiologists who contend for the inhalation of caloric as a distinct substance, to be produced by its separation from the inspired air of the atmosphere, and the union of a part of its oxygen with the hydrogen furnished by the lungs. In health, this vapour is very freely exhaled by the mouth, and forms that mist which is seen to issue from every man's lips in frosty weather, and especially when thrown upon a dark polished surface, as that of a mirror. But, if the bronchial vessels be obstructed by a more than ordinary increase or accumulation of mucus, it escapes with difficulty; and, encountering the air that is thrown into the lungs, occasions that hissing or wheezing sound, which is always produced by a current of air when it has to force its passage through a body of dense vapour. Commonly, therefore, this is a case of atony, local or general; and, like the last species, will be best relieved by those medicines that gently stimulate, and warm, and give power to the bronchial lymphatics, as the resinous gums, and the bulbs of the alliaceous plants. In fat people, and especially those who are low of stature, short-necked, and oppressed with fat about the chest, the obstruction is chiefly the result of infarction and pressure; for the diaphragm and other muscles not having full play, the lungs are never thoroughly expanded, and the extricated vapour is put into a smaller space, and has a narrow exit. And here the only cure must consist in taking off the obesity by repeated venesections, active purgatives, vigorous exercise, and a low diet.

GENUS IV.
APHONIA
DUMBNESS. SPEECHLESSNESS.

INABILITY OF SPEECH.

WE now proceed to a group of diseases that affect not so much the trachea or general avenue of sound, as the organs of articulation fixed on its upper end, like a capital upon a pillar, as M. Blumenbach has elegantly observed, and consequently which impede or vitiate the power of speech. These have been very differently arranged by different writers, and have often been very unnecessarily extended and

complicated, especially by Vogel, as may be seen by a reference to the commentary in the author's volume on Nosology. Upon the whole, they will be found to distribute themselves most easily and distinctly under the three following generic divisions:—Defects that depend on an utter inability of speech; those in which the sound of the voice is imperfect or depraved, and those in which, while the sound of the voice continues unaffected, the articulation is incorrect or vitiated. It is the first of these divisions that constitutes the genus before us.

Inability of speech may proceed from three different causes, each of which lays a foundation for several symptoms peculiar to itself, and consequently for the three following species:—

1. Aphonia Elinguium. Elingual Dumbness.
2. ——— Atonica. Atonic Dumbness.
3. ——— Surdorum. Deaf-dumbness.

SPECIES I.
APHONIA ELINGUIUM.
ELINGUAL DUMBNESS

SPEECHLESSNESS FROM DESTITUTION OF TONGUE.

This may be of two sorts; each of which lays a foundation for very different results:—

- a Congenita. The defect coeval with the birth.
- β Oblæsa. The defect produced by accident, punishment, or disease.

The glottis is the chief organ employed in dividing the voice into distinct or simple tones or notes; as the tongue chiefly divides it, either singly, or by a co-operation with other organs, into distinct articulations, so as to form proper language, which is hence commonly regarded as nothing more than a modification of the powers of the *lingua*, as the *tongue* is called in Latin; and hence *tongue* and *language* are often used synonymously. It is obvious, therefore, that, in all common cases, the man who is deprived of his tongue, whether by congenital defect, by mechanical force, or by disease, must at the same time be deprived of the power of speech and become dumb.

I say in all common cases; for a privation of the tongue is not always accompanied with dumbness. It is not necessarily so in all cases of congenital destitution, and still less in all cases of privation that occur after speech has been acquired. In the Physiological Proem to the present Class we had occasion to remark, that the glottis alone, in some instances, either from a greater pliancy and volubility of the muscles proper to it, or from the possession of some superadded muscle or membrane, seems to have a power of forming distinct articulations without the assistance of the tongue: and I hence endeavoured to account for that singular talent, which we denominate ventriloquism. But there is a more singular talent still, that sometimes occurs in the history of the human voice, and which is probably resolvable into the same cause; for we have examples, supported by indisputable authentication, of persons who, hav-

ing lost the entire organ of the tongue, and a few of them of the uvula also, have still retained a power of speaking, and even of expressing themselves with a clear and accurate enunciation. Such examples, indeed, are not very common; but they seem to have occurred in all ages, and especially when it was the barbarous custom among the Turks, Goths, and other half-civilized nations, to cut out the tongues of the unhappy wretches, whom the chance of war had thrown into their hands as prisoners.

Some persons profess to disbelieve all the stories of this kind, for the mere reason that they have never witnessed any thing of the same kind in their own age or country. But such persons would have also joined the King of Siam in disbelieving the Dutch ambassador's assertion, that the rivers in his own country became so hard and solid during the winter, that men and women could walk and skate upon them. The accounts are too numerous, and in many instances too well supported, to be treated with skepticism; and all that is left to our judgment and ingenuity is not to deny the evidence, but to account, as we shall presently proceed to do, for the fact.

Hundreds of cases might be quoted upon this subject; but the following may be sufficient, though others are referred to in the nosological system, which may be examined at the reader's leisure. Those now selected are taken from recent times, and from authorities that may indeed be disbelieved, but cannot be disputed.

In the third volume of the *Ephemerides Germanicæ*, we have the history of a boy who, at eight years of age, lost the whole organ of the tongue, in consequence of a sphacelus proceeding from the smallpox, and who was able to talk after its separation. The boy was exhibited publicly, but a trick was generally suspected; in consequence of which the boy and his friends were summoned to appear in court before the members of the celebrated university of Saumur. In the presence of this learned body, he underwent a strict examination as to the loss he had sustained, and the lingual powers he still possessed. The report was found correct; and the university, in consequence, gave their official attestation to the fact, in order, as it expressly asserts in its records, that its reality might not be called in question in succeeding times.

In the *Mémoires de l'Académie des Sciences* for the year 1718 is an account of a girl who was born without a tongue, but had nevertheless learned to speak, and talked as easily and distinctly as if she had enjoyed the full benefit of that organ. The case is given by a physician of character, who had accurately and repeatedly examined the girl's organs of speech, and was desirous that others should examine them also.

About seventy years ago, our own country furnished us with another equally striking example of the same power, and which forms the subject of various papers in the *Philosophical Transactions*, drawn up chiefly by Dr.

Parsons at the time, and printed in the volumes that were published between the years 1742 and 1747. It is the history of a young woman of the name of Margaret Cutting of Wickham-market, near Ipswich, in Suffolk; who, when only four years old, lost the whole of her tongue, together with the uvula, from what is said to have been a cancerous affection; but still retained the powers of speech, taste, and deglutition, without any imperfection whatever: articulating, indeed, as fluently and with as much correctness as other persons; and articulating, too, those peculiar syllables which ordinarily require the express aid of the tip of the tongue for exact enunciation. She also sung to admiration, and still articulated her words while singing; and could form no conception of the use of a tongue in other people. Neither were her teeth in any respect able to supply the place of the deficient organs; for these also were but few, and rose scarcely higher than the surface of the gums, in consequence of the injury to the sockets from the disease that had destroyed the tongue. The case, thus introduced before the Royal Society, was attested by the minister of the parish, a medical practitioner of repute, and another respectable person. From its singularity, however, the Society evinced a commendable tardiness of belief. They requested another report upon the subject, and from another set of witnesses, whom they themselves named for the purpose, and for whose guidance they drew up a line of categorical examination. This second report soon reached the Society, and minutely coincided with the first; and, to set the question completely at rest, the young woman was shortly afterward brought to London, and satisfied the Royal Society in her own person.

To explain this unexpected power, we should not only turn our attention to what is actually and in our own day accomplished by ventriloquists, but should recollect, that the tongue is only a single organ employed in the articulation of sounds, and that the fauces, nostrils, lips, and teeth, bear, at least, an equal part, while the glottis, which forms all the vocal or vowel sounds, is the chief organ of the whole. In reality, out of the twenty-four articulate sounds which fill up our common alphabet, the only two in which the tongue takes a distinct lead, are the *l* and *r*, though it is auxiliary to several others; but the guttural, or palatine, as *g*, *h*, *k*, *q*; the nasal, as *m*, and *n*; the labial, as *b*, *p*, *f*, *v*, *w*; most of the dental, as *c*, *d*, *z*; together with all the vowels, which hold so large a space in our vocabularies, are but little indebted to its assistance.

It is singular that so delicately sensible an organ as the tongue should receive the severest injuries, and submit to very violent operations, with less serious mischief than almost any other organ of the same size in the body. And it is on this account that the cruel and barbarous manner in which the tongue was extirpated by the ferocious tribes that overran Europe from the east formerly, was rarely productive of fatal consequences. Sir Everard Home published,

many years ago, a paper upon this subject, containing various cases of sections of the tongue to a less or greater depth in consequence of diseased action. The operation was in every instance performed by the ligature. He does not state what effect was in any instance produced on the speech, and we are hence led to conjecture, that nothing in this respect occurred of material importance; but he draws the following conclusions:—The internal structure of the tongue is less irritable than almost any other organized part of the body. Its nerves appear to be more easily compressed and deprived of their power of communicating sensation, than nerves in general; and any injury done to them is not productive of diseased action in the trunk of the injured nerve. The tongue also has the power of throwing off its sloughs in a shorter time than any other part.

SPECIES II.

APHONIA ATONICA.

ATONIC DUMBNESS.

SPEECHLESSNESS FROM ATONY OF THE VOCAL ORGANS.

This atony is chiefly, if not altogether, confined to the nerves of the vocal organs, which may be injured by violence, or exhausted by mental or other commotion, independently of the occurrence of the disease occasionally as a symptom of paralysis, quinsy, or catarrh; thus furnishing us with two distinct varieties:—

- a* Oblæsa. From lesion of the nerves of the tongue or glottis.
- β* Soluta. From sudden or overwhelming commotion, or shock of any kind.

The instances of speechlessness produced by an injury of the lingual nerves are not common. But a division of the recurrent nerves, which are offshoots from the par vagum, and distributed over the larynx and glottis, produces a speechlessness that is rarely, if ever, recovered from; for here the muscles belonging to the arytenoid cartilages, being rendered atonic or paralytic, can never be brought duly to contract again, the glottis remains permanently open, and the diameter of the larynx suffers no variety of contraction or dilatation. Galen seems to be the first anatomist who noticed this effect, or rather ascribed it to its real cause; for it was known, before his time, that, by making ligatures on the bloodvessels of the trachea, the noisiest animal is immediately struck dumb, and made quiescent. It was supposed that the state of the bloodvessels themselves, and not of the nerves included with them in the ligature, was the cause of this effect; that the blood became intercepted in its passage from the heart, and that the animal became mute because rendered comatose: and hence the name of carotids, or soporific vessels (from *καρπος*, *sopor*), was given to the arteries whose ligature was supposed to produce this very singular result. Galen, however, demonstrated very satisfactorily that the dumbness is, in this case, en-

tirely owing to the pressure of the ligature on the accompanying nerves: and he afterward produced to his opponents two cases of boys, who in a greater or less degree had lost their voice in consequence of the recurrent nerves being cut by surgeons unacquainted with anatomy, in extricating strumous tumours from the neck. In the one case, only one of these nerves was divided, and the voice was merely much weakened, or about half destroyed; in the other, both were divided, and the voice was lost altogether. A whizzing senseless noise, indeed, remains in most instances, as Vezalius has correctly observed; but there is no vocal sound, articulate or inarticulate.

Where the speechlessness has followed upon an injury of some branches of the lingual nerves, we have numerous examples of recovery. In one instance the dumbness ceased suddenly, after the patient had been speechless for not less than ten years.—(*Sammlung*, 1721, ii., 406, 503, Bresl.)

In other instances, dumbness is produced suddenly, from a total exhaustion of nervous power in the vocal organs, without any organic lesion whatever. A sudden and overwhelming emotion of the mind from terror, anger, or any other passion, has frequently had this effect in irritable habits. So has a violent fit of hysterics, or any other vehement shock which* instantaneously deprives the nerves of their sensorial power, and the muscular fibres of their irritability: as a stroke of lightning, or a severe and unexpected blow on the stomach, will sometimes exhaust the vital energy of the entire system, and make life immediately cease. A sudden chill, as from drinking cold water during a violent heat, or the shock of a sudden fall, has frequently produced it, of which numerous instances are recorded in the Ephemerides of Natural Curiosities. Speechlessness of this kind has sometimes arisen from deleterious exhalations; from eating mushrooms; and in one instance, recorded in Hufeland's Annals, by repeatedly rubbing the wound made by a poisonous insect with saliva, and as often putting the finger to the mouth to obtain a supply of fresh fluid.—(*Dupau*, in *Journ. de Médecine*, Sept., 1789.) In like manner, Bonet informs us that the same effect has followed from putting into the mouth a piece of money cankered with the rust of verdigris.—(*Bonet*, *Scpulchr.*, lib. i., § 22.)

Where medical aid is required, our dependence must be on tonics, local or general, and topical stimulants. Blisters and masticatories have chiefly been made use of, and frequently with good effect; as has the vellication of a hair-brush contrived for the purpose. The dumbness has sometimes yielded to emetics, at others to electricity (*Krazenstein*, *Pr. Hist. res. Loquelæ par Elect. Hafn.*, 1753), and, in a few cases, to a cough (*Iperen. Abh. aus holl. Schriften*, b. i., p. 356; *Morgagni, De Sed. et Caus. Morb.*, ep. lxiii., art. 15); and occasionally the same, or a like violence which occasioned the

* Büchner, *Miscell.*, 1729. Bartholin, *Act. Hafn.* i., Obs. 101, Schurig, *Chilologia*, p. 205.

disease, has removed it, and the cause has become the cure; as is reported of Athys, the son of Cæsus. In like manner, we have examples of its having yielded abruptly to a fit of anger, or terror; in one instance, to a fit of laughter (*Ipercn.*, op. cit.); in another, to a blow on the head.—(*Ephem. Nat. Cur.*, dec. iii., an. v., obs. 236.)

SPECIES III. APHONIA SURDORUM. DEAF-DUMBNESS.

SPEECHLESSNESS FROM DEAFNESS, CONGENITAL OR PRODUCED DURING INFANCY.

THE ears are as necessary to speech, or articulate sounds, as the tongue, or even the glottis; for, if such sounds be not heard, and distinctly discriminated, they can never be imitated. Persons who become deaf after a thorough acquisition of speech, do not become dumb, for the very reason that articulation has already formed a habit, and can easily be preserved by practice. But, if deafness be congenital, or take place antecedently to such habit, articulation can never be acquired afterward, unless, by some rare good fortune, the ears should acquire hearing; and the unfortunate individual can only receive and interchange ideas by the eye, through which medium, however, he may be taught written, though not oral language, and thus still, happily for himself, have his mind almost as richly stored, though not his ideas as readily communicated, as through the outlet of speech. Persons thus organically defective are denominated *sourds-muets*, or *sordi muti*, on the continent, and sometimes deaf-dumb among ourselves.

[In eastern courts, it has been usual from time immemorial to retain a number of mutes. These are not only employed to amuse the monarch, but also to instruct his pages in an art, to us little known, of communicating every thing by signs, lest the sound of their voices should disturb the sovereign. The mutes are also the secret instruments of his private vengeance.—(*See Edin. Med. Journ.*, vol. vii., p. 61.)]

This is an interesting subject, and not unconnected with pathological science, since it opens to us the only remedy that can be resorted to, where the defect before us, or that of deafness prior to articulation, is the subject of discussion. It is interesting also to us from the very considerable proportion of human beings which in all countries, and, apparently, in all ages, have been sufferers from this melancholy affection; a proportion that has been ingeniously calculated from a comparison of various tables, deduced from the extent of the disease in different parts of the world, as amounting to 1 in 2441 individuals.—(*Quarterly Journal of Foreign Med.*, vol. i., p. 319.) [In Germany, it is estimated that, in every million of people, one hundred are deaf and dumb; and, in the Danish dominions, the deaf and dumb amounted to 515 in the different bishoprics, whose population was only 820,621, according to returns, made

at the first anniversary of the Copenhagen Institution for this class of afflicted persons. In Bornholm, the proportion was still greater.*—(*Allgemeine Literatur Zeitung*, June, 1807.) And it is peculiarly lamentable to observe that, when the defect has once made an entrance into a family, whether from the influence it produces on the nervous system of the mother, or from any other less obvious cause, it is particularly apt to become common to those children which are born afterward: inasmuch that we often meet with a third, or a half, and, in a few instances, where the first-born has been thus affected, with every individual of the progeny, suffering from the same distressing evil. "The late investigation in Ireland discovered families in which there were two, three, four, or more, thus circumstanced. In one family there were five children, all deaf and dumb; in another, seven; in another, ten; and, in that of a poor militia officer on half-pay, there were nine born deaf and dumb in succession."—(*Quarterly Journ. of Foreign Med.*, vol. i., p. 321.) Yet it is consoling to reflect that the defect is not always propagated to a succeeding generation, when the deaf-dumb have married, and even when both the husband and wife have been thus afflicted. [Still, it is said that such propagation is not uncommon (*Edinb. Med. Journ.*, vol. vii., p. 62), and, as deafness is, without doubt, often hereditary, the experiment of marriage should be carefully avoided.]

To pursue the calamity, however, into the various plans which the benevolence and ingenuity of the human mind have invented to supply the defect of speech, from the times of [Juan Pabbo Bonnet,† of Madrid], Ammanus of Amsterdam, and Wallis of our own country, to the wonderful degree of perfection attained under the Abbé Sicard, in the Royal Institution at Paris, would carry us far beyond the limits to which the present work must be confined. And I shall therefore only observe, that the grand principle laid down under almost all the

* According to a late census, the United States, with a population including slaves of 12,854,874, contain 7136 deaf mutes. The estimated proportion of deaf mutes to the population, as given in the *Troisième Circulaire de l'Institut Royal des Sourds Muets de Paris*, 1832, varies materially from that stated by Dr. Good. A census of 47,339,952 souls gives 29,853 deaf mutes; being about as 1 to 1585. Switzerland presents the greatest proportion of deaf mutes to her population, of any country in Europe. Reports from five cantons show, that of a population of 895,000, 1777 are deaf mutes; being nearly as 1 to 500. In the canton of Berne the proportion is as 1 to 350; while in the commune of Weyach, it is as 1 to 63. The number of institutions, in Europe and America, for the instruction of these unfortunates, as stated in the French report, is 128, at which about 3732 deaf mutes are pupils. For many interesting facts on this subject, see *An Address, &c.*, delivered by Dr. Samuel Ackerly, formerly Physician and Sec. to the New-York Deaf and Dumb Institution, New-York, 1826.—D.

† Reduccion de las letras y arte para ensennar a ablas los Muets. En Madrid, 1620, 4to. The earliest known work on the subject of instructing the deaf and dumb.—Ed.

various plans and systems that have been devised, in order to obtain the proposed remedy, and supply the want of speech, is that of commencing with picture-characters, and making these the key to alphabetical and arbitrary signs: and, in this manner it is, that the eye is rendered subservient* to the purposes of the ear. When the deaf-dumb scholar is made to understand that the picture of a knife or of a ship is to be regarded as the representative of such objects or ideas, there is no great difficulty in teaching him that the arbitrary letters of which these words are composed, and which for this purpose are always written or should be written underneath these pictures, are intended to stand for the same purpose as the pictures themselves, and to import the same objects or their ideas, whenever they are met with in a certain arrangement: and so of other pictures, and other combinations of letters which are equivalent to them. And hence, such combinations of letters, when the learners are accustomed to them, will as effectually become the signs or representatives of the objects they are intended to express, as the pictures which preceded their use. The power that appertains to each separate letter is a lesson to be learned long afterward; and still longer afterward an idea, for it can never be any thing more, of the vocal or articulate effects produced by different movements of the lips, cheeks, and throat, which that letter is designed to express.* An accurate and habitual attention, however, will teach the scholar this; and he will, in a considerable degree, be able to make out what is spoken by the motion of the lips and other vocal organs alone; and, if he possess a facility of copying these, he may be taught, still farther, how to measure and modulate them, so as to produce the articulations they are intended to convey, and to speak with tolerable accuracy, without hearing himself: while a fellow-scholar labouring under the same defect, and having made an equal progress in the same kind of education, will understand his meaning, or the vocal terms he conveys, by the mere movement of the vocal organs alone. I have myself borne a part in such conversations at that excellent institution of this metropolis, the Asylum for Deaf and Dumb Children, and have seen scholars conversing in this manner without hearing a single syllable on either side, but at the same time with a perfect understanding of each other's meaning.

Mr. Waller relates a singular case of this kind, in a man and his sister, who lived together to an advanced age, neither of them having the least sense of hearing, but who understood each other as well as other persons by the motion of the lips alone; supporting themselves by daily labour. They became deaf,

* See the Abbé de l'Épée's *Institution des Sourds et Muets par la voie des signes méthodiques*, &c., Paris, 1776.

As also the Abbé Sicard's "*Théorie des Signes, ou Introduction à l'étude des langues; où le sens des mots, au lieu d'être défini est mis en action*," tom. ii., 8vo., 1808.

however, when children, after they had learned to speak; and hence, in moving their lips, they continued to articulate, though not very distinctly.—(*Phil. Trans.*, vol. xxv., 1707, No. 312, p. 2468.)

[A curious account is given by Bishop Burnett of a girl at Geneva, who could hold a conversation in the dark, by laying her hand upon her companion's lips. The possibility of such a circumstance, it is said, has not been confirmed by subsequent experience. The mode adopted for conversing in the dark, is by writing the word intended to be communicated upon the palm of the hand, or the back of the neck, thus addressing the sense of touch, which, as well as that of sight, is rendered by attention and exercise wonderfully acute.—(*Edin. Med. Journ.*, vol. vii., p. 62.)]

I have said that the mode of commencing instruction in almost all the schools of the kind before us, is by pictures or other imitative signs, and that a knowledge of alphabetical characters does not take place till long afterward. The limitation is introduced, because in a few of the French schools in the present day, and particularly that at Bourdeaux, under the superintendence of the Abbé Gondelin and M. Gard, this easy and natural order is reversed, and the tutors have voluntarily loaded themselves with a very unnecessary difficulty, and their scholars with a useless and incomprehensible burden of many months' duration. For what reason the disciples of the Abbé Sicard, or of the Abbé de l'Épée, should thus intricately deviate from the plain and simple path of their masters, it is not easy to conceive.

The extent of knowledge, and even the expansion of genius, which the deaf-dumb have occasionally exhibited, are truly marvellous; of which, indeed, M. Gard himself, to whom we have just referred, is a striking example. This gentleman was born with the faculty of hearing, and only lost it in his seventh year of childhood: so that his mind must have become stored with a multitude of ideas, derived from the inlet of hearing, which he could not have acquired afterward. It is said that, in consequence of his deafness, he so completely lost the power of speech, as to forget even the commonest words that had been familiar to him. This feature, however, in his history seems to be considerably overcoloured; yet, it is well known, that he did not commence any plan of education till he was twenty-seven years old: from which time, such was the vigour of his mind, and the assiduity of his pursuit, that the able and professional critic, to whom I have just referred, affirms, "he is perfectly well informed upon all subjects which are usually studied; well versed in history, literature, politics, and languages. He has been taught Greek and Latin; and has, by himself, acquired the English language, of which he even showed us a grammar written for his own use. On presenting him with a printed report of one of our institutions, he immediately translated a part of it into French.—(*Quart. Jour. of Foreign Med.*, vol. i., p. 322, 1819.)

Yet it is well known, that there are several

other scholars of the same school that have excelled even M. Gard; and who, having been born perfectly deaf, have been necessarily dumb, from the same period; of whom it may be sufficient to mention M. Clerc and M. Massieu. The last was literally taken from the plough, in the department of the Gironde, and was carried by a stranger, who happened accidentally to see him, and took compassion on him, to M. Sicard, at that time stationed at Bourdeaux. By dint of hard study, and a comprehensive capacity, he has also raised himself to the office of assistant instructor to M. Sicard, in the Parisian school, where he teaches the departments of syntax, history, geography, and religion. On one occasion, happening to be robbed, he pleaded his own cause in the court of justice; and when, during the French revolution, his revered master was put into prison, he addressed a letter of so much force and feeling to the President of the National Assembly, as to obtain his liberation.

There are a few instances on record of a recovery from deafness many years after birth, and of a gradual acquisition of speech in consequence hereof; chiefly produced by some violent but fortunate affection of the brain. Thus Lambzweerde relates the case of a fortunate fracture of the scull, through a fall from a considerable height, by which a young person, deaf-dumb from birth, was suddenly endowed with hearing, and, in process of time, with speech.—(*Append. ad Amani.*) In like manner, Mr. Martin gives an account of a native of Strathcraig, near Inverness, of the name of Fraser, who was born deaf, and continued dumb till seventeen years of age, when he was attacked with a fever which affected his brain for some time; on recovering from this he began to have a sense of hearing, and soon afterward to understand speech, which he gradually imitated, and at length acquired, so as to converse fluently; though, from commencing at so late a period, he never attained perfect accuracy in articulating many words.—(*Phil. Trans.*, vol. xxv., No. 312, p. 2469.)

[Rosenmüller has dissected most carefully the organs of hearing and of speech in persons born deaf, but could discover nothing peculiar in them. As a means of cure, he has tried galvanism without success, and it has been tried by others quite as ineffectually. One child suffered acute pain during the application of the pile, and seemed to be benefited for a month, but afterward relapsed.]

Puncturing the tympanum has been recommended by M. Delear (*Journ. Complémentaire*, *Juin*, 1822); and in a few instances with ourselves, as well as abroad, it has succeeded. It is hence worth trying, though the success has been very rare.

[In 1825, the particulars of a deaf-dumb boy, to whom the faculty of hearing was first communicated when he was nine years old, were read to the Royal Academy of Sciences at Paris. The treatment from which this success was derived, consisted in injecting air and fluids into the tympanum through the Eustachian tube; a

practice very commonly adopted by Dr. Itard. The boy, named Claude Honoré Trézel, had a physiognomy of little expression; the emblem of his understanding. He slodged and reeled about as he walked; could not even blow his nose; and made his principal wants known by signs. The first few days immediately following the first establishment of his hearing, were a period of ravishment to him. All kinds of noises gave him excessive pleasure; and, while listening to a musical snuff-box, he seemed in a sort of ecstasy. But it was some time before he could comprehend, that speech was a means of social communication. Hence, at first he did not attend to the sounds by which it was formed, but only to the movements of the lips. For this reason, he fancied that a child, seven years old, spoke exactly like grown-up persons. At length, however, he was taught, that the sounds were of more importance than the motions specified. In this stage of improvement, he unluckily happened to hear a magpie utter some phrases, and, generalizing from this particular fact, he inferred that all animals were gifted with speech, and he actually beat a favourite dog to make it pronounce "*papa*," "*du pain*," the only words he could himself speak.

These first advances in hearing produced a considerable alteration in the boy's physical state. His gait became firmer, his dull countenance assumed a smiling gay air, and he learned to blow his nose. A month passed away without much further improvement; and it was a quarter of a year before the lad could understand a few compound words, and the meaning of some plain short phrases. It was a good while also before he could ascertain the direction of sound. Hence, when a person concealed himself in his room, and called him, he had the utmost difficulty in finding out the place in which the speaker was hidden, and then traced it rather with his eyes and reason than his ears.

The earliest sounds which he acquired the power of forming, were low and grave; and the first words which he learned to speak were, "*papa*, *tabac*, *du feu*," &c. But when he wished to pronounce more complex words, he exhibited various contortions of his lips, tongue, and all the agents of pronunciation, the uses of which he was completely ignorant of; resembling in this respect a beginner in dancing or swimming, who exhausts himself by useless ungraceful efforts. At last he succeeded in pronouncing a few compound words which had previously baffled him. His progress continued, however, to be very slow; and he either skipped over many syllables, or pronounced them imperfectly. Perhaps, indeed, he would never have overcome this difficulty, had not the plan of instructing him through the sense of vision, instead of through that of hearing alone, been put in practice. Various syllables were now written down, and pointed out to him; and, from this period, his pronunciation improved fast, as he comprehended with greater clearness the assemblage of vowels and consonants, and their reciprocal influence. Here, as M. Magendie observes, we see a very remarkable fact; namely, that the

association of vision with the motion of the larynx was prompt and easy, while that of hearing with the organs of voice was always difficult, and but slowly acquired. Thus, when the boy looked at the written syllables, and they were pronounced near him, he could pronounce them himself; but if the writing were removed, the clearest pronunciation of certain syllables, close to him, did not enable him to articulate them himself.

By dint of the foregoing method, the boy learned to read and write tolerably fast; but, like persons who study a foreign language, and who generally learn to read and write it long before they can speak it, he still reads with his eyes, and writes infinitely better than he speaks. One curious circumstance is particularly recorded: whenever a word is distinctly pronounced to him, he immediately repeats it. For instance, when he is called, he never fails to repeat his name. When his preceptor tries to make him understand things, it is by gestures and looks; the means by which the boy himself most readily expresses his own ideas.

The improvement of his condition is wonderful: a year previous to the date of this history he was so deaf that he was insensible of the loudest explosions; he now hears all noises very well; knows whether they come from a distance; can distinguish their nature; gets out of the way of carriages and horses, and runs to open the door when it is knocked. He relishes music, and understands and repeats by memory certain phrases within his compass, and gives answers to them. He is also able to do what his tutor directs him to do by words, though he cannot yet do this with other persons.

Finally, as M. Magendie observes, when it is reflected how much the boy must have learned to attain his present improved state; what new ideas and combinations must have taken place in his mind; what instinctive associations must have been formed between his ear and understanding, between this and his organ of voice, and his ear and his larynx, there is every reason to hope that his moral and physical state will yet continue to receive further melioration.—(*Journ. de Physiol. Expér.*, tom. v., p. 223, &c.)]

GENUS V.

DYSPHONIA.

DISSONANT VOICE.

THE SOUND OF THE VOICE IMPERFECT, OR DEPRAVED.

VOICE, as we have already observed, is the sound of the air propelled through, and striking against the sides of the glottis: while speech is the modification of the voice into distinct articulations, by means of particular muscles in the cavity of the glottis itself, or in that of the mouth or the nostrils, employed as signs of ideas. Hence, voice belongs to many animals in common with man: speech, thus limited as to its object, belongs to man alone: for no other animal can distinctly articulate, and make use of articulations, as signs of what is occurring in

the mind: though a few animals may be taught to imitate articulate sounds without having ideas attached to them. The present genus embraces the inorbid affections to which the voice is subject; the next, those which appertain to the speech. It includes three species:—

1. Dysphonia Susurrans. Whispering Voice.
2. ————— Puberum. Voice of Puberty.
3. ————— Immodulata. Immelodious Voice.

SPECIES I.

DYSPHONIA SUSURRANS.

WHISPERING VOICE.

VOICE WEAK, WHISPERING, AND SCARCELY AUDIBLE.

MANY of the causes of atonic dumbness, when operating with a less degree of violence, become causes of the present affection, while a few are peculiar to itself. The following varieties may not unfrequently be noticed:—

- | | |
|-------------------------|--|
| <i>a</i> Oblæsa. | From lesion of the nerves of the larynx. |
| <i>β</i> Pathematica. | From sudden emotion of the mind. |
| <i>γ</i> Compressorica. | From permanent compression of the trachea. |
| <i>δ</i> Catarrhalis. | From neglected catarrh. |
| <i>ε</i> Enervis. | From simple debility of the larynx, without any obvious cause. |

Independently of which the present species is occasionally met with as a symptom in melancholic, paralytic, and hysteric affections, as also in quinsy, dysphagia, and catarrh.

The nerves which, when injured, chiefly produce whispering, are the recurrent. When these are divided, dumbness, as we have already observed, is the result; but they are often weakened, and, perhaps, otherwise injured, without being divided: and in this case the voice is not actually lost, but dwindles to a whisper, and is recovered as soon as the nerves resume their tone. The voice has, in this manner, frequently been injured by straining the ligaments and the minute muscles which move the parts of the glottis on each other; and in elevating the voice to a high pitch in public addresses, or striving at a note in singing which the natural compass of the voice will not reach. So Pliny tells us, that the voice of Gracchus, during a violent exertion in speaking, suddenly sunk to a feminine treble. Astringent gargles, blistering the throat, cold local bathing, external and internal, with perfect quiet and silence, are the best means of recovering the voice under such circumstances. The last I have found most serviceable, and have made the patient gargle four or five times a day with ice-water, which, at the same time, should be applied to the throat with a wet napkin.

A sudden and overwhelming emotion of the mind from various causes, will sometimes totally choke or stifle the voice, which is particularly the case with rage: but, where the effect is not so violent, the voice becomes an almost inaudible

whisper, and particularly when the passion is fright or terror. Rest, and return of confidence, will usually restore it in a short time; but in some instances the effect has been permanent.

There are various cases in Morgagni and Bonet, in which the voice was rendered almost inaudible from the pressure of an enlarged heart, a bronchocele, or an aneurism of the aorta against the vocal avenues. Sauvages has referred to these; and it is highly probable that such a pressure, by diminishing the capacity of the trachea, may lower the power of the voice.

A catarrhal whisper is a frequent occurrence, and there can be few practitioners who have not met with examples of it. The voice is often injured from the commencement of the catarrh, as well in consequence of the inflammatory affection of the mucous membrane of the glottis, as of the increased secretion of mucus that issues from the interior of a great part of the trachea: and in some cases in which the inflammation had become chronic, by pulling forward the tongue, I have seen the epiglottis covered with a cream-coloured coating, which was probably extended lower, and was the chief source of the difficulty of utterance. But the variety before us is the result of that weakness which inflammatory action induces in the vocal organs, as a sequel, rather than a symptom, of the inflammatory action itself.

Mr. Archdeacon Squire relates a singular case of this kind in an attorney at Devizes, of the name of Axford, who, at twenty-eight years of age having caught cold, was seized with a hoarseness that in six days rendered him totally speechless; in which state he continued after the cold left him, being totally incapable of distinct articulation, and scarcely able to make the least inarticulate sound. Four years afterward, he got so much intoxicated as to fall from his horse several times on his way home; and was at last taken up by a neighbour, and put to bed in a house on the road. He fell asleep; and dreaming that he had fallen into a furnace of boiling wort, he was put into so great a fright, that struggling with all his might to call for help, he actually did articulate aloud, and recovered the use of his speech from that moment as effectually and perfectly as he had ever had it in his life.—(*Phil. Trans.*, vol. xlv., 1747–8, p. 148.)

For habitual hoarsenesses, leading to the present affection, the siliquosæ offer the best class of medicines; and, with respect to many of them, there is no great difference, except what results from their greater degree of acrimony. It is common to all these, on being swallowed, to stimulate the fauces, and especially their mucous glands, and thus to excite a more copious excretion of mucus. Of this family of medicines the *crisimum officinale*, or hedge-hyssop, was at one time in higher reputation for habitual hoarseness than any of the rest: and Dr. Cullen seems disposed to support this preference, chiefly upon the ground of its being less violent in its stimulant power than the generality of them. He recommends the juice of this plant, mixed with an equal quantity

of sugar or honey into a sirup. And where the *crisimum* is not at hand, he recommends its place to be supplied with a sirup of horseradish, but made weak, so that it may be frequently used, or long continued, without rendering the fauces sore or uneasy.—(*Mat. Med.*, part ii., class v., p. 166.) For this purpose, a drachm of the root, fresh and scraped, may be infused in four ounces of boiling water for two hours in a close vessel, and made into a sirup with double its weight of sugar. Of this a tea-spoonful, swallowed leisurely for a dose, will often be found highly serviceable.

We sometimes meet with a debility in the organs of the voice which reduces it to a whisper, without being able to ascribe it to any particular cause.* This is often temporary, and seems to occur from a sudden deliquium of nervous power in these organs; as when, in the middle of speaking or reading, and this too in an agreeable tone, the voice abruptly fails, and is as abruptly resumed. In the case of the orator Gracchus, to whom I have just adverted, Pliny informs us that the voice was restored by the sound of a pipe, that, being struck by his servant, gave the proper pitch. In some instances, however, this failure of the voice has been more or less permanent or intermissive. I had lately a lady under my care, of about forty-five years of age, who was usually attacked in sudden and irregular paroxysms, each continuing for several weeks. Repeated blisters, stimulant astringent gargles, as of port-wine or alum-water with tincture of myrrh, and a steady perseverance in a tonic regimen and pure country air succeeded. She recovered by degrees the full power of her voice, which, during the paroxysms, was nothing more than a weak and almost inaudible whisper; and has had no return of the affection for several years. In another case of the same kind, adverted to in the Nosology, the same plan proved less successful. The patient was a gentleman of about forty years of age, otherwise in good health, who had never spoken, except in a whisper, for more than eight years. [Electricity, galvanism, and tonic medicines might be tried; and, in a few examples, the editor has known the application of strong liniments, blisters, and antimonial ointment to the integuments covering the larynx, give the voice its proper strength.†]

* A variety of aphonia sometimes arises from the long abuse of mercury in cases of this kind. For the cure of this, an alterative and tonic mode of treatment should be pursued. Dr. Francis has found stimulating gargles and the free use of the *alliaceæ* to be useful in restoring the functions of the parts.—D.

† Dr. Elliotson refers in his lectures to a species of aphonia, in which the voice is sometimes lost, or reduced to a mere whisper, without any inflammation, œdema, or obstruction of the parts. It occurs chiefly in females, and is regarded altogether as a nervous complaint. Frequently it comes on suddenly, and ceases in the same manner, and is sometimes accompanied by other nervous affections. The shower-bath, and attention to the general health, are the means of relief advised by Dr Elliotson.—Ed.

SPECIES II.

DYSPHONIA PUBERTUM.

CHANGE OF VOICE. VOICE OF PUBERTY.

THE VOICE DISSONANT AND UNTRUE TO ITSELF, IRREGULARLY ALTERNATING FROM HARSH TO SHRILL : CONFINED TO THE AGE OF PUBERTY.

THE change that, during the period of puberty or adolescence, takes place in the sexual system for the purpose of giving perfection to its organs, is well known to be connected, by sympathy, with an equal change in various other parts of the body. In females, the breasts assume a soft and beautiful swell, and the nipples a pleasurable irritation. In males, the chin is covered with a beard, and the voice becomes fuller, deeper, and more sonorous. Before the voice, however, acquires this important change, it often exhibits great irregularity ; and the youth, incapable of modifying his own tones, passes abruptly from harsh to shrill, and from grave to acute. And it is this irregularity and uncontrollable dissonance of voice, which constitutes the present species.

There is no great difficulty in accounting for this abnormal state of the voice, at the period before us. The glottis is nearly as complicated in its structure as the eye or the ear, and the modulation of its tones depends upon an equal degree of elasticity and pliability in all its moveable parts, and in their perfect submission to the authority of the will. To the attainment of a correct voice, it is necessary that there should be great accuracy of ear ; a perfect symmetry of the vocal organs ; equal tenseness in the ligaments of the larynx, which must be also nicely balanced by the powers of the muscles on each side ; the cartilages of the larynx must be delicately adjusted to each other ; the lateral cavities equally deep, and the cornua of the os hyoides of a like length. With such an organization, the voice is perfected for exact modulation in speaking or singing ; and it is from different defects in this requisite mechanism, that some persons cannot speak, and others cannot sing in tune.

Now in the change that takes place during puberty, every part does not always harmonize with the rest ; some parts become more tense, others less, and yield more easily ; some are more relaxed, others more contracted ; and of the effect produced by such a state of the glottis, a tolerably distinct idea may be formed from a remark of Dodart, that a variation in the capacity of the glottis, not exceeding the fifty-fourth part of a silkworm's thread, or one three hundred and fifty-fourth part of a hair, will occasion a difference of tone. Time, however, and repeated exercises of the will, usually triumph over these discrepancies, wherever they exist, in a few months ; when the voice recovers its unity of tone, and becomes graver in proportion as its motive powers become firmer and denser ; and hence the reason why the voice of males is graver than that of females. In males, also, the glottis becomes more capacious, which forms another cause of gravity of tone. THE

VOL. I.—R

deepest tones are struck by animals that have the largest glottis, as the phoca, the ox, the *ardea stellaria* ; while singing-birds which sound the acutest tones, have a glottis capable of the closest contraction. The deepest roarings are produced by animals that have the cartilages of the trachea entire, or imbricated, or tessellated with bones, as the lion, the elephant, and the peacock.

SPECIES III.

DYSPHONIA IMMODULATA.

IMMELODIOUS VOICE.

THE VOICE PERMANENTLY DEPRAVED, OR INHARMONIOUS.

THIS species offers the six following varieties :—

- | | |
|----------------------------|--|
| <i>a</i> Rauca. | The voice naturally or |
| Rough or harsh voice. | habitually hoarse, harsh, or rough. |
| <i>β</i> Nasalis. | The voice sent with a |
| Speaking through the nose. | cracked and grating sound through the nostrils. |
| <i>γ</i> Clangens. | The voice shrill and |
| Squeaking voice. | squalling. |
| <i>δ</i> Sibilans. | The voice accompanied |
| Whizzing voice. | with a whizzing or hissing sound. |
| <i>ε</i> Stertens. | The voice accompanied |
| Guttural voice. | with a snorting, snoring, guttural, or stertorous sound. |
| <i>ζ</i> Palatina. | The voice hoarse, obscure, indistinct, with |
| Palatine voice. | a fissure, or other defect, in the palate. |

Of most of these, the cause will be obvious from the observations already offered. Thus the squeaking voice proceeds ordinarily from too narrow a glottis ; the rough or harsh voice, from a glottis too wide, and not sufficiently moistened with mucous secretion. In the whizzing voice there is too much secretion, but of too limpid a consistence.

The guttural, or stertorous variety is commonly the result of a relaxed glottis, or velum palati, with an accumulation of thickened mucus ; and here local stimulants, astringents, and tonics, together with a steady and determined exertion to obtain a modulated voice, will frequently prove successful. If we put out of consideration a few cases, in which some fissures in the palate have been cured on the principles applied to the harelip, the obscure palatine voice, commonly congenital, but sometimes a sequel of lues, can only be assisted by filling up the fissure in the palate with a silver plate, properly secured by a spring, or, when necessary, by an entire false palate of the same metal. Yet the most dexterous artist will sometimes find his ingenuity unavailing, and the defect beyond his skill. The nasal voice is produced ordinarily by an obstruction of the nasal fossæ from condensed mucus, as in a cold of the head, a polypos, or some other organic defect ; the remedy

or removal of which, where this can be attained, will restore the voice to its proper clearness. In common language, we denominate this variety *speaking through the nose*, but most incorrectly; for it is occasioned alone by our not having the nasal passages clear; and consequently from not being able to speak through them with our usual facility.

This last is often the result of affectation, or a foolish habit, not easy to be conquered when once acquired.

GENUS VI.

PSELLISMUS.

DISSONANT SPEECH.

THE ARTICULATION IMPERFECT OR DEPRAVED.

In the preceding genus the imperfection or depravity exists, not in the articulation, but in the sound of the voice; whence the distinction between that and the present is clear. Psellismus embraces two species; that of STAMMERING, and that of a VICIOUS ENUNCIATION.

- | | |
|-------------------------|-------------------|
| 1. Psellismus Bambalia. | Stammering. |
| 2. ————— Blæsitas. | Mispronunciation. |

SPECIES I.

PSELLISMUS BAMBALIA.

STAMMERING.

THE FLOW OF THE ARTICULATION DISTURBED BY IRREGULAR INTERMISSIONS OR SNATCHES.

This affection may be regarded as a sort of clonic spasm, or St. Vitus's dance, confined to the vocal organs, and offers us the two following varieties:—

- | | |
|--------------------|-------------|
| <i>a</i> Hesitans. | Hesitation. |
| <i>β</i> Titubans. | Stuttering. |

In the HESITATING VARIETY, there is an involuntary and tremulous retardation in articulating peculiar syllables. The organs are generally too mobile and unsteady, and the will has lost its control over them, if it ever possessed any. By reverting to the remarks made on *Dysphonia puberum*, the physiology of the affection will be easily understood. As bad habits are more easily learned than good ones, because they are more striking, and more strongly arrest the attention, this complaint is often caught by imitation, and especially among children; who, for this reason, ought never to be intrusted in the company of a stutterer, till their speech has become steady and confirmed.

In the SECOND VARIETY, we have a higher degree of stammering than in the first; accompanied with more impetuosity of effort. It consists in an involuntary and tremulous reduplication of some syllables, alternating with a tremulous hurry of those that follow. "I would thou couldst stammer," says Shakspeare, with a striking illustration of this morbid affection, "that thou mightst pour out of thy mouth, as wine comes out of a narrow-mouthed bottle, either too much at once, or none at all."

The convulsive actions of the muscles of the glottis, and which are communicated to the

other organs of speech, whether productive of the present or the preceding variety, may often be overcome by a firm and judicious discipline; insomuch that some of the most distinguished orators of both ancient and modern times are well known to have been subject to this affection in their youth. In ordinary conversation, or where a man has time to pick out single words, instead of speaking whole sentences, the stammerer always hesitates most; and hence always least where his attention is completely engrossed. On which account, there are many stammerers that scarcely utter a word in speaking without betraying themselves, who nevertheless sing, and enunciate the words of the song, without any hesitation whatever, their whole mind being led away with the tune, and a strong desire to keep in time and harmony; while there are others who hesitate as little in reading, the words being immediately before them, and their attention being swallowed up in the subject. One of the worst stutters I have ever known was one of the best readers of Milton's *Paradise Lost*. He was a scholar of considerable attainments, and had taken some pains with himself for his natural defect, but without success; yet the moment an interesting poem was opened, his defect completely vanished, from his being led captive by the force of the subject, and the great interest he took in this branch of polite letters.

This affords us one means, therefore, of remedying the evil before us; the stammerer should learn by heart and repeat slowly whatever most arrests his attention. But, at the same time, he will must learn to obtain a control over the muscles of articulation; and, for this purpose, single words should be uttered for hours at a time deliberately, and when alone; and perhaps too, as was the custom of Demosthenes, a practice of haranguing by the seashore, or on the brink of some awful waterfall, where the fearful noise and the magnificence of the scenery have a tendency to break in upon the habit, and render the conquest the easier, may be often found advantageous. It would at least stimulate the speaker to strain his voice to the full extent of its power, and thus fit him for public speaking before large bodies of people, where a loud and elevated voice can alone be heard distinctly; which was probably the chief object Demosthenes had in view; for we are expressly told, that his voice was weak, as well as his speech tremulous and hesitating. Adults who have firmness and perseverance enough for the purpose, may undertake the task of disciplining themselves; but children should always be put under the care of a judicious tutor, whose best qualifications will be patience and good temper. A very few words only should be marked down at a time for trial, and these should be attempted separately; nor should a second lesson be entered upon till the first has been completely mastered, although the effort should demand many weeks, or even months. An acquisition of one lesson will always facilitate that of another.

[Dr. McCormac (*Treatise on the Cause and Cure of Stammering*, Lond., 1828, 8vo.) con-

ceives, that the cause of stammering arises from an attempt to speak while the lungs contain an insufficient quantity of air. This habit, he says, is acquired from undue haste and imitation; and the successful method of treatment consists in making the patient always inhale a proper quantity of air into the lungs before he attempts to speak, and to direct him always to pronounce very slowly, until the bad habit is broken. When the patient stutters very much, the practice of making long inspirations and expirations is stated to be a good preliminary exercise. The main thing to be attended to, and what in fact is the groundwork of the whole system of cure (Dr. M'Cormac says), is to expire the breath strongly each time when attempting to speak, the lungs being previously filled to the utmost. As it will be some time before the patient can husband the air of his expirations, so as to say all he would wish in one breath, he must not commence by repeating sentences during each expiration, but only simple monosyllabic sounds. During the intervals, all conversations should be avoided, until the cure is somewhat advanced. It appears to the editor, that although the practice here inculcated is unquestionably right, the theory on which it is founded is not altogether so free from doubt. While the practice recommended by Dr. M'Cormac comprises slowness and deliberation, which are, indeed, indispensable parts of it, the theory of the lungs not having air enough in them, and of this being the cause of the infirmity, may not be correct. The voice of some stammerers whom the editor has known, has been so strong as scarcely to justify such a conclusion; and he is still inclined to believe, that a want of proper control over the muscles concerned in articulation, must be regarded as the chief cause of the present affection. At the same time it must be granted, that the attempt to speak while the lungs have so little air in them, that an interruption will arise from the necessity of a fresh inspiration, cannot fail to embarrass a person addicted to stammering. The practice inculcated, therefore, is in every respect commendable, and the suggestion of it highly meritorious.]

SPECIES II.

PSELLISMUS BLÆSITAS.

MISENUNCIATION.

ARTICULATE SOUNDS FREELY, BUT INACCU-
RATELY ENUNCIATED.

THE elementary articulate sounds which the organs of speech are capable of enunciating are but few; and hence they are the same in all languages, which are alone founded upon them: differently, indeed, modified in several of them, and with a difference of number in still more; for diversities of language consist, not in different sets of articulations, to which the vocal organs are not competent, but only in their different modes of combination, and the different ideas which such combinations indicate. So seven notes comprise the whole of music, and by their different arrangements, pro-

duce that variety of harmony which we admire in the works of Handel or Mozart. If we would ascend higher than eight notes, we only commence another series of like proportions. In the same manner, to quote the words of the author of *Hermes*, "it is only to about twenty-four plain elementary sounds that we owe that variety of articulate voices, which have been sufficient to explain the sentiments of so innumerable a multitude as all the present and past generations of men."—(*Book iii., chap. ii., p. 324.*)

The twenty-four plain elementary sounds here referred to, are those which are denoted by the letters of the greater number of our European alphabets. Yet, of these, many are rather mere modifications of other sounds than distinct sounds in themselves; inasmuch that the ingenious Wachter has endeavoured to reduce the twenty-four to ten primary articulate enunciations, and to show that these alone would be sufficient for the purposes of the most polished languages; and, consequently, that an alphabet of not more than ten marks or signs might be sufficient to express its entire range.* In making this reduction, he regards all the five vowels as modifications of each other, or rather of one common articulation, the simplest belonging to the organs of speech, formed with least difficulty, and, on this account, composing a very great part of the languages of savage nations. In like manner, he regards all the gutturals as only modifications of another common articulation, as *k, c, ch, q, g, h*. So *b* and *p* have nearly a common sound; as have *d* and *t*; and *ph, v, and w*. While *l, r, s, m, and n*, are distinct articulations, and will not readily blend with any others.

These, no doubt, might be sufficient for all the purposes of speech; for we find that ten simple numerals are adequate to all the purposes of arithmetical calculations, which extend to infinity; and that able mathematician Tacquet, who has worked the problem for the purpose, informs us, that the combinations capable of being produced by the ordinary series of twenty-four letters, amount to not less than 620,448,401,733,239,439,360,000, without any repetition.—(*Arith. Theor., p. 517, edit. Amst., 1704; Astle, ut supra, p. 20.*) So that the richest vocabulary has made but a small inroad into that inexhaustible mine of wealth which the wisdom of Providence has bestowed upon the few distinct and primary sounds, be they more or less, which the vocal organs of man are capable of articulating; thus devising a plan, which is equally entitled to our admiration for the simplicity of its design, and the comprehensiveness of its power.

I have observed, that some languages have more elementary sounds than others; and as these are expressed by elementary characters or letters, it follows, that some languages must also have a more extensive alphabet than others. The proper Phœnician alphabet, which is, perhaps, the oldest of which we have any distinct

* Nat. et Script. Concord., p. 64; Astle, Origin and Progress of Writing, p. 20.

account, seems to have consisted of not more than thirteen letters at first ; it had afterward three added to it, making sixteen in the whole ; and, in this state, it seems to have been earliest employed by many of the adjoining countries, and is distinguished by the name of the Samaritan, or ancient Hebrew : for the terms and characters of this last are so nearly those of the Phœnician in its improved form, that it is difficult and altogether unnecessary to make a distinction. The Chaldeans introduced some change into the shape of the letters, rendered them more elegant, and added six other letters, as the Samaritan alphabet did not seem sufficiently full to express all the articulations of their speech ; and the Jews, during the Babylonish captivity, readily adopted the improvement, and have continued the Chaldaic characters in their writings ever since. And, in this manner, with various changes and augmentations, the Phœnician alphabet can be traced through every part of ancient and modern Europe, every region of Africa where writing of any kind is current, and the western countries of Asia.

Over a very extensive portion of this last continent, however, we meet with an alphabet that has no common origin, or conformity of principle, with any hitherto described. This is the Nagari, or Devanagari, as it is called by way of pre-eminence. It consists of not less than fifty letters, of which sixteen are vowels, and thirty-four consonants, all arranged in the order of the alphabet, with a systematic precision that is to be found nowhere else. The vowels take the lead, beginning with those most easily uttered, and terminating with those that approach towards a consonant sound. The consonants then follow, in five regular series of gutturals, compounds, palatines, dentals, and labials ; the whole closing with letters symbolical of sounds that do not exactly enter into any of the preceding series, and which may be regarded as a general appendix. This alphabet is asserted by many learned Bramins to be of a higher antiquity than any other ; and there can be no doubt that it has a just claim to an exceedingly remote date. But its very perfection is a sufficient confutation to its having been invented first of all. Something far more rude and incondite must have preceded, and paved the way for it : and, in the complex characters of which it consists, we seem to have the relics of those emblematic or picture-symbols, which, there can be little doubt, were first made use of ; which are still employed by the Chinese and the uncivilized tribes of America, and seem to have laid a foundation for alphabetical characters in every quarter of the world. With a few trivial variations, this correct and elegant alphabet extends from the Persian Gulf to China ; but it has no pretensions to rival the antiquity of the Phœnician. It is unborrowed, but of later origin.

Whatever be the number of simple articulations that enter into the constitution of a language, or however modified in enunciation, they can only be learned with accuracy in early life, when the vocal organs are most pliable, and the

untutored infant is most prone to imitation. And hence, unless care be taken to imprint upon the organs of speech a just and correct enunciation of the first elements of words at this time, it is with great difficulty that the art can be acquired afterward. This occurs to us under the best and most favourable circumstances. Foreigners coming into our own country after the age of thirty, though urged by an ardent desire of speaking English, seldom pronounce the language tolerably. An Englishman at the same age can hardly be taught to utter the guttural sound which the Welshman gives to the Greek χ , or even the French sound of the vowel u : and of the stray and solitary savages that have been caught in the forests of Lithuania, and a few other regions, there is not, perhaps, a single instance of their having been able, after the age of manhood, to articulate any language, so as to be understood with facility.

But we sometimes meet with less favourable circumstances to an acquisition of proper articulate sounds, and this too in a state of childhood, which is the immediate age of imitation. For, firstly, we sometimes see children, brought up under the care of those who have a vicious articulation themselves, from whom they will be sure to catch it ; and hence those pronunciations and rude dialects that are so frequently found in the remoter and less polished districts of almost every extensive people. Secondly, we occasionally meet with some natural disability or want of harmonious power in the organs of speech themselves ; one or two of them evincing a greater mobility than the rest, and consequently taking the lead of them, and interfering with their office. And, thirdly, there is, not unfrequently, a defect of structure in the organs of articulation, as a want or loss of the fore teeth, or a fissure in the palate or the lips.

Many of the articulate sounds, moreover, in most, perhaps in all languages, though called simple, are produced by the joint exertion of two or more distinct organs : and unless these organs precisely accord in flexibility and power, and are equally under the command of the will, the sound will be imperfectly imitated. The Arabic ث and the Saxon ð or þ , in English expressed by *th*, is an articulation of this kind, being compounded of a dental and an aspirate or guttural sound. From early habit, the natives of both countries are able to enunciate it perfectly, and they enunciate it alike. But there is scarcely an individual in any other country, who can ever be taught to sound it accurately, unless he should have an opportunity of trying it in early life ; for the motive powers concerned in the sound will not move in sufficient unison. For the same reason, it is as difficult for a foreigner to catch the German *ch* in the pronoun *ich*, the *sch* in *schätzen*, or both in *schädlich*, or *schmächtigkeit*. But even these combined sounds have sometimes shades of distinction which constitute other sounds, and are expressly intended to do so ; and, in such cases, the difficulty of an accurate enunciation is

greatly enhanced. Thus the English *th* in *thing*, and in *thou*, is a different articulation; and the Arabians, who have both, express them by different marks or letters; for the sign of the first mode is **ث** and of the second **ض**, which,

if expressed by our own letters, would, perhaps, be best written *dth*. And it is on this account, that where a common language spreads over different countries, as the Arabian, or different parts of a country, which formerly made use of a diversity of tongues, as the English, varieties will necessarily take place in the utterance; and the dialectic may be more in favour than even the original or normal enunciation. There are some persons who prefer the English of Edinburgh to that of London; and the Arabic of Delhi, Ispahan, and Constantinople, has modifications of sounds as well as of inflections, which, though regarded as barbarisms by a native of Cairo, are contemplated as excellences by those who make use of them.

The organ chiefly employed in the articulation of sounds, is the glottis; and subordinate to this are the fauces, the nostrils, the tongue, the lips, and the teeth. And hence the division of articulate sounds into VOWEL or VOCAL, which are formed by the glottis alone, and are the simplest of all sounds; GUTTURAL, or those which are formed in the fauces more or less acting conjointly with the glottis, of which the fauces are only a continuation, as *h, ch, q, g, h*; NASAL, as *m, n*, and the compound *ng*; LINGUAL, as *l* and *r*; LABIAL, as *b, p, f, v, w*; and DENTAL, as *c, d, t, z*.

If we were to be more particular than we have time to be, or than is necessary, it would not be difficult to derive very numerous examples of vicious enunciation, and consequently varieties of the species of morbid utterance before us, from every one of these divisions; but the following are the chief which occur in our own tongue, and those that are cognate with it:

- α Ringens. Vicious pronunciation of the letter R.
- β Lallans. Vicious pronunciation of the letter L.
- γ Emolliens. Vicious substitution of soft for harsher letters.
- δ Balbutiens. Vicious multiplication of labials.
- ε Mogilalia. Vicious omission of labials, or exchange for other letters.
- ζ Dentiloquens. Vicious employment of dentals.
- η Gutturalis. Vicious pronunciation of gutturals.

THE VICIOUS PRONUNCIATION OF THE LETTER R is produced by a harsh or aspirated vibration or redoubling of it. Examples of this inelegance are common to several of the northern provinces of our own country, as it is to the ruder provinces of France. Among the Greeks, from the letter ρ (*ro*), it was denominated rotacismus, and was common to the Eretrienses in the Island of Eubœa. It is generally ascribed to the

possession of too large and tardy a tongue. But it is rather produced by pressing the point of the tongue downward towards the root of the teeth of the lower jaw, instead of upwards, with a slight vibration towards the palate.

In the SECOND VARIETY of vicious enunciation, the letter *l* is rendered unduly liquid, or substituted for an *r*. As when delusive is pronounced delusive, as though the *l* possessed the power of the Spanish *ll*, or the Italian *gl*; or as when parable is pronounced pafable. Alcibiades is said to have laboured under this defect. The Greeks, from the letter λ (*lambda*), denominated this *lambdacismus*; the Romans, with more severity, *lallatio*, or *lullaby-speech*. This is often the result of affectation; sometimes, perhaps, from not having the tongue sufficiently free, as where there is too great a breadth of the frenum which ties it to the base of the mouth, or too large and oppressive a flow of saliva. As the articulation of *r* does not enter into some languages, as those of Mexico and China, the *l* is often substituted for it; hence the Jews of the former country, who, from long disuse, have lost the power of pronouncing the *r*, employ the *l* in its stead; and for the first Psalm, read **אשרי האיש אשר** in the opening of the first Psalm, read **אשרי האיש אשר**.

In the NEXT VARIETY, the harsh letters are viciously dropped for softer; as in the substitution of *anzel* for *angel*; *capitol* for *capitol*; *dat* for *that*. This may be the result of a debilitated articulation in children who have been brought up too daintily; but it is more usually the result of affectation; or is founded upon a general principle of softening the rougher or harsher sounds of a language into a smoother and more limpid flow; as is the case with most of the modern dialects of the south of Europe, and particularly those of Italy and Spain, which are well known to be derived from the Latin. Thus, in the former, we have *piano* for *plano*; *piangere*, and still further *piagnere*, for *plangere*, and *egli* for *ille*: and in the latter *llamar* for *clamare*; *llaga* for *plaga*, and *hermosa* for *formosa*.

It is curious to observe how, in this respect, the most barbarous and the most polished languages agree. It is generally, but erroneously conceived, that the former are peculiarly harsh and dissonant; for savages, in speaking, as in any other exertion, take no more pains than are absolutely necessary, and hence content themselves with the soft and simple vowel sounds, or those of the glottis, drawled out indeed at too great length; and when they are driven to the use of consonants, select those that give them least trouble to enunciate. On this account Lord Monboddo is correct in observing, that "the words of barbarous languages are long, and full of vowels; not short, and full of consonants, as has been imagined."* And the following remark of my excellent and distinguished friend, Dr. Perceval, of Dublin, in the manuscript commentary with which he favoured me

* Origin and Progress of Language, second edit., vol. i., b. iii., p. 496.

on the volume of Nosology, already spoken of in the Preface, is peculiarly in unison with this statement :—"In a paralytic affection of the organs of articulation, the patient pronounced the word *cocoa*, *toto*. The Otaheitans call Cook, Toote. Their language is beautifully soft and vocal. A sentence, reported in Cook's second voyage, is distinguished by the harmonious and expressive collocation of its words : 'Tootaha, taio Toote—mutte Tootaha.'—Tootaha, the friend of Cook—dead is Tootaha." Man, in savage life, is fond of ease, and would not move a muscle if he could help it : in the voluptuousness of polished life he loves it equally, and is, if possible, still less disposed to exertion : and hence this extraordinary accordance in the character of their articulations.

In the BALBUTIENT VARIETY, we have the labial letters too frequently repeated, or enunciated too harshly, or used instead of other letters. The Welch are proverbially addicted to this inelegance, by confounding the *v* with the *f*, and the *b* with the *p*; of which Sir Hugh Evans, in the *Merry Wives of Windsor*, affords a correct and amusing example :—"Ferry goot," says he, "I will make a prief of it in my note-book !" So *infringe* is often used for *infringe*, and *ibory* for *ivory*. And thus *Veda* is pronounced *Beda*, and *Venares Benares*, in Bengal, the Bengalee having no such letter or articulation as *v*.

Infants, before they cut their teeth, are constantly using labials too freely, as the lips press together without resistance ; and hence they delight in iterating the same labial sound ; and it is from a copy of such infantile iteration, that we derive the names of *pa-pa* and *ma-ma*, which they first learn to utter : for the original Hebrew terms, from which these names have descended to Europe, and, indeed, to most other parts of the world, savage as well as civilized, are without any iteration whatever, being simply *אב* (*ab*) *אם* (*am*) ; the first importing *love*, and the second *sustenance* ; in Syriac rendered *aba* or *abha*, and *ama* ; and the same in Chaldee : whence the Greek terms and their correlatives, *πάππα* or *πάππας* and *μάμμα* (*pappa* or *pappas* and *mamma*), produced by a mere infantine balbutiation, or substitution of *p* for *b*, in the first term, and a reduplication of the consonant in each : and hence, too, *am-o* and *am-or*, in Latin.

Persons in a state of intoxication, from the tremulous debility of their lips, often exhibit the same reduplication of the labial sounds ; and thus make an approach towards one of the varieties of the last species. It is also often to be found in persons whose lips are unduly thick and broad, a deformity distinguished vernacularly by the name of *lobber-lipped* : to which cause Quintilian, who notices this variety of vicious expression, chiefly ascribes it, and hence distinguishes it by the name of *plateiasma*, probably from Theocritus (*Idyl.* xv., 88) :

Τρυγόνες εκκνίσαιεντι πλατυσδοῖσαι ἀπαντα.

"Cooing like pigeons with your blobber lips :"

A verse designed to ridicule the Doric dialect, and consequently intimating that this kind of vicious enunciation was common to a considerable part of Achaia.

The erroneous articulation constituting the NEXT VARIETY, is of a character precisely opposite to the preceding ; and consists in omitting the harsher labials altogether, or exchanging them for others that are softer and more easily uttered.

Thus *mantle* is broken down into *antle*, *fish* into *vish*, and *pilfer* into *filfer*. So in the Spanish the Latin *farina* becomes *harina*, and *fabā*, *hara*, and in French the Latin *sibilo*, *siffler*. This blemish is especially common to those who are hare-lipped, or have any other kind of defect in either lip, so that the two will not play in harmony ; and more particularly still, if any of their front teeth be wanting.

In the DENTILOQUENT VARIETY, the dental sounds, as of *c*, *s*, *t*, *z*, are too frequently employed, producing the effect of what is called lispings, or in common language, speaking through the teeth. This, also, is often an affected blemish, as though it were an elegance, instead of a fault in enunciation. It is produced by having a tongue naturally too long, and hence perpetually thrust against the front teeth from necessity, and from a habit of pressing it in this direction too frequently.

The CUTTURAL or PALATINE LETTERS, as *g*, *h*, *j*, *c*, *z*, are sometimes uttered imperfectly, by being introduced where they ought not, or withheld where they should be distinctly enunciated ; and in this consists the last variety it may be necessary to notice.

One of the most common examples is in the superfluous use of the aspirate, or *h*, by means of which exalt and exasperate are pronounced *exhalt* and *exhasperate* ; so collar is called *khollar*, and custom *khustom*. And not unfrequently among men of unfinished education, the aspirate is just as uniformly omitted where it ought to be employed, as employed where it ought to be omitted ; whence for this sentence, "the upper part of the house is to be let unfurnished," we have "the hupper part of the ouse his to be let hufurnished." And if the palate be fissured, or in any other way imperfect, "ghost" is pronounced "host," "jolly," "iolly," or "yolly," "coffee," "dhoffee," "Xerxes," "Zherzes."

Where these defects depend on organic misformation, they will mostly be found without a remedy, though they may be palliated by a laborious discipline. Where they are the result of debility or vicious habit, the remarks with which we closed the preceding species will be equally applicable here.

ORDER II. PNEUMONICA.

AFFECTING THE LUNGS, THEIR MEMBRANES OR MOTIVE POWER.

THE RESPIRATION IRREGULAR, IMPEDED, OR PAINFUL.

THE idiopathic diseases that appertain to this order, differ very widely in their respective degrees of severity and danger; and, upon the whole, are but few; though the number is very considerable in which the lungs and their auxiliary powers are deeply implicated, by sympathy or continuity, in disorders that originate in other organs, and primarily affect other functions.

The genera are as follow:—

I. Bex.	Cough.
II. Dyspnœa.	Anhelation.
III. Asthma.	Asthma.
IV. Ephialtes.	Day-mare. Night-mare.
V. Sternalgia.	Suffocative Breast-pang.
VI. Pleuralgia.	Stitch.

GENUS I.

BEX. COUGH.

SONOROUS AND VIOLENT EXPULSION OF AIR FROM THE LUNGS.

THIS genus of diseases was by the Latins named *tussis*, a term that has been more generally employed by nosologists than any other. I have ventured, however, to restore the Greek name *BEX* (*BHE*) for the sake of uniformity; so that the generic terms may all be derived from a single tongue.

Cough, defined as above, is well known to accompany, as a symptom, a great multiplicity of other affections, some of which are very remote from the seat of coughing. Thus it occurs to us in pleurisy, in pneumonitis, hepatitis, paristhmitis, empyema, asthma, catarrh, phthisis, hæmoptysis, hysteria, helminthia, and dropsies of various species. Hence Dr. Cullen has omitted cough as an idiopathic affection, and has only introduced it as a symptom or synonyme of catarrh; although it belongs at least as much to phthisis, and perhaps to every one of the diseases just enumerated: but Dr. Cullen's system did not allow a place for cough as a primary disease; and in this, as in various other cases, he was obliged to bend to the force of necessity.

Cough, undoubtedly, occurs in its most frequent appearance as a symptom of some other complaint; but it is at times as truly idiopathic as any complaint whatever, and ought to be treated of as such. Under this form, its seat is in the chest; and the parts principally affected are the trachea, bronchiæ, the membranes, and substance of the lungs. In the act of coughing, the lungs, like the stomach in vomiting, continue inert; and the active or convulsive part, by which the lungs are emptied, is performed by the muscles of respiration.

"It is not necessary," observes Mr. John Hunter, "that the stomach should act violently

to produce the evacuation of its contents; nor is it even necessary that it should act at all: for the lungs themselves do not act in the least when any extraneous matter is to be thrown up: and coughing is to the lungs what vomiting is to the stomach. The muscles of respiration are the active parts in emptying the lungs, and can act naturally and preternaturally. The action of vomiting is performed entirely by the diaphragm and abdominal muscles; and we know by the same action that the contents of the rectum can be expelled."—(*Anim. Economy*, p. 199.) In the *Physiological Proem* to the present class, I have endeavoured to establish this remark in respect to the lungs; and, under the species *EMESIS*, in the preceding class, I have noticed experiments of M. Magendie that confirm Mr. Hunter's opinion in respect to the stomach.*

Generally speaking, idiopathic cough is not dangerous in itself, or while running its regular course; but it has often proved highly dangerous in its results, by superinducing peripneumony, hæmoptysis, hectic fever, or phthisis.

The whole of these remarks apply not more to common coughs than to pertussis, or whooping-cough: which unquestionably, therefore, ought to be arranged as a species under the present genus. In truth, the commencement of both is in most cases so much alike, that it is often impossible, and always difficult, to distinguish them. Both are, in many cases, accompanied with a slight degree of fever; the most obvious and assignable cause of both is cold; I mean, where the whooping-cough is original; and in both, the sonorous fits, how much soever they may differ in violence and a few other circumstances, are produced by a spasmodic action of the same muscles.

Thus explained, the genus *bex* or *tussis* may be divided into the three following species:—

1. *Bex Humida.* Common or Humid Cough.
2. — *Sicca.* Dry Cough.
3. — *Convulsiva.* Whooping-cough.

SPECIES I.

BEX HUMIDA.

COMMON COUGH. HUMID COUGH.

THE COUGH ACCOMPANIED WITH AN EXPECTORATION OF A MUCOUS OR SEROUS FLUID.

TO this species the Greeks gave the name of *anaptyxis*, and *anacatharsis*; which last has been copied by Sauvages, and appropriated to the present purpose. The species affords us four varieties; one *entonic*, or accompanied with an excess of power, and three *atonic*, or distinguished by enfeebled action.

- a* Mucosa. Common mucous cough.
- β* Anhelans. Chronic cough of old age.
- γ* Acrida. Frothy saline cough.
- δ* Periodica. Nervous cough.

In the *FIRST VARIETY*, the discharge is chiefly mucous, and excreted freely. The exhalants

* The opinions of various other physiologists on the mechanism of vomiting will be found at p. 27, and 93, of the present vol.

of the bronchiæ are stimulated by an irritation of some kind or other, frequently by a reverse sympathy, in consequence of cold and torpid feet, to act more powerfully than in a state of ordinary health, whence the bronchial vessels become overloaded, and relieve themselves by an expectoration, that takes place freely, and without the hoarseness which usually accompanies catarrh, or any other very troublesome disturbance of the respiratory organs.

There is another variety, commonly called the CHRONIC COUGH OF OLD AGE, which occurs in long paroxysms, with a viscid and mucous discharge, excreted with difficulty and laborious breathing. Here the bronchial secretion of mucus is perhaps less copious than in ordinary health; and, being peculiarly tenacious, is thrown up with great labour and repeated efforts. This kind of cough is particularly common to persons in advanced life; or whose lungs, or bronchial vessels, are rendered weak and irritable from a neglect of common mucous coughs; which have at length run into the present variety, and become almost habitual; showing themselves on every change of the atmosphere; and particularly during the inclemency of winter.

In the THIRD, or ACRID VARIETY, the fluid coughed up is thin, frothy, and saline; and for the most part excreted with difficulty. It is evidently, like the last, an atonic affection of the lungs; though often produced by diseased action in some remote organ with which the lungs associate. It is hence sometimes found in transferred gout, and still more frequently in cases of diseased liver; especially where the liver has been affected from a habit of ebriety; and, in these cases, it is peculiarly troublesome on first rising from bed in the morning. There is, as I suspect, in this form of humid cough, not only great torpor and imbecile action in the mucous membrane of the lungs, but a depraved secretion, small in quantity, and thinner and more acrid in quality than it ought to be.

This cough is sometimes extremely pertinacious. Dr. Darwin tells us that he met with it twice in the same person, at a distance of some years, during a fit of gout, so intractable as to resist venesection, opiates, bark, blisters, mucilages, and all the usual methods. It was, for a time, supposed to be the whooping-cough, from the violence of the spasmodic fits of coughing: it continued two or three weeks, the patient never being able to sleep more than a few minutes at once during the whole time; and never for a moment, unless propped up in bed with pillows.—(*Zoonom.*, Class iv. ii., 1, 9.)

There is another variety of the present species to be met with, which develops a striking tendency to recur at STATED PERIODS. The cough, instead of being violent, is here partly restrainable, and the discharge, though thin, is not acrid. It is the NERVOUS COUGH of Dr. Whytt, who, in his Treatise on Nervous Diseases, has described it with great accuracy and judgment. It is a frequent attendant upon persons of a nervous or irritable temperament, and hence common to the hysteric, dyspeptic, and choleric. Like the last variety, it is also occa-

sionally found in repelled gout. There seems here, also, to be some depravation in the nature of the secretion, dependant on the debility of the secreting organs. And hence we sometimes find, that the morbid phlegm forms a nidus, as in various cases of phthisis, for the eggs of minute insects floating in the atmosphere, which are conveyed with the inspired air to the bronchial vessels, where they are hatched in the secreted fluid, and often thrown up in the shape of larvæ or maggots. In like manner, we sometimes meet with hydatids formed and thrown up in the same way; of which we have a singular example in the Medical Transactions, in a lady, thirty-seven years of age, of a delicate constitution, and nervous or hypochondriacal habit. For half a year, she expectorated more or less of these in the midst of thick viscid phlegm, sometimes to the amount of twelve, fifteen, or twenty-four in a day, of various sizes, from that of a pea to that of a pullet's egg.*

From the difference of causes and symptoms which these varieties evince, a very different mode of treatment is evidently required.

The first variety, produced by excess of action in the mucous membrane of the lungs, and mostly by sympathy with a remote organ, as in the case of cold and torpid feet, will be best relieved by diaphoretics and the warmer sedatives; and especially the compound powder of ipecacuanha, which will restore to the system its harmonious balance of power. The warm bath, or bathing the feet in warm water; warm and copious apozems, and oily or mucilaginous demulcents, are also peculiarly adapted to this species of cough. At the same time, the bowels should be kept open by any gentle laxative, as the neutral salts, or the confections of cassia or senna.

On the continent it has lately been a very popular practice to employ tartar-emetic in preference to ipecacuanha, whether alone or combined with opium, as in the compound powder. It has been given in all complaints of the chest attended with defluxion, and in all possible proportions: in some instances, so diluted with water as to form a part of the common beverage; and, in others, so concentrated as to rival our boldest wholesale prescribers of calomel. This is especially the practice of the supporters of the contra-stimulant Italian school. Thus Rasori has given a gradual increase of tartar-emetic, to the amount of two drachms a day; and, according to his account, without producing vomiting, except in the first instance. He adds, that when the patient gets better, the emetic property again comes into operation, and the remedy is left off. M. Peschier of Geneva has imitated this innovation. He declares bleeding to be useless, and that he cures all fluxions of the chest with tartar-emetic alone, which he

* Dr. Elliotson, in his Lectures at the London University, mentions a case which he met with, where a communication was formed between a cyst full of hydatids and the air-passages, so that the patient was in the habit of coughing up hydatids for some time before she died.—Ed.

gives in doses of fourteen grains in a day, without producing vomiting. And Dr. Duffin has lately informed us, that he swallowed from twenty to twenty-five grains of tartarized antimony by mistake, but without suffering from any remarkable symptom. From all which we may learn, I fear, that, in the present day, the powers of experiment are more widely afloat, than the powers of judgment and sobriety.*

In the disease before us, we have also reason to expect benefit from many of the expectorants, properly so called; those medicines, which rather promote the separation of the viscid phlegm with which the bronchiæ are loaded, than simply inviscate or dilute it, though these are also treated of as expectorants by many writers.†

The list of the proper expectorants employed formerly was very voluminous; in the present day, they are comparatively but few, and the proscription has, perhaps, been carried too far. The principle upon which they act is, in some degree, doubtful. The simplest way of accounting for it is, by means of a specific determination to the lungs. For, as we have pretty clear proofs of medicines operating specifically upon other organs, as that of mercury upon the salivary glands, and cinchona upon the irritable fibre, there is no reason why we should not expect a like operation upon the viscera of the chest. Dr. Cullen is quite at a loss upon this subject, from not admitting of specific medicines, or a specific action upon any organ. As a general rule, he supposes expectorants to operate on the bronchiæ merely by a diaphoretic power, or that of increasing the flow of the superficial exhalants at large, and consequently of the exhalants of the lungs, by which the mucus present in the follicles may be poured out in a less viscid form, and hence in a state to be more easily thrown up by the trachea.

But this is a very unsatisfactory view of the question. For, first, admitting that some medicines act directly upon the exhalants of the skin, a specific power is hereby immediately conceded to one set of organs; and if such power exist in respect to one set, there is no reason why it may not in respect to fifty. Next, we see evident proofs of an expectorant power in many medicines, as in gum-ammoniac, where we have no proof whatever of increased exhalation from the surface of the body. And further, the general explanation gives us no clew to the different operations of particular expectorants.

It is possible that in all these there is a peculiar stimulus; but whether this depends upon

any sensible quality they possess, we cannot easily determine: for though many of them are more pungent to the taste than others, their degree of expectorant power does not in every instance keep pace with their degree of pungency.

In the variety, however, of a common mucous cough from cold, it is obvious that where expectorants are employed, they should be of a mild rather than of an acrimonious nature, as we have already an excess of action to encounter. And hence honey, the rob or jelly of the sub-acid fruits, as currants or raspberries, liquorice-root, and perhaps hyssop, butterbur, and inula, may be used with advantage, though the virtues of the last two or three are but doubtful, notwithstanding the high repute in which they were held formerly. The official inula of our own day, however, does not appear to be that of the Latins; for among them its farina is represented as having been particularly sapid; so much so, indeed, as to have formed a favourite ingredient in the most celebrated sauces of their public feasts. Horace speaks of it in one place (*Sat.*, lib. ii., viii., 51) as possessing a bitter taste; for he thus makes an epicure boast of having invented the sauce:—

“—INULAS ego primus AMARAS
Monstravi incoquere.”

And in another (*Sat.*, lib. ii., ii., 44), he describes it as acrid, or stimulating; for it is probably in this sense that the ACIDAS should be understood:—

“—ACIDAS mavult inulas.”

While Lucretius (*De Rer. Nat.*, ii., 430) makes it rather a mild general stimulant, or aromatic:—

“—quæ
TITILLARE magis sensus, quam lædere possint,
Fæcula jam quo de genere est, INULÆQUE saporēs.”

But let the quality of the Roman inula be what it may, we do not seem to possess the plant in the almost tasteless and inert root employed under this name in our own day.

In the second variety, or chronic cough of old age, where the mucous discharge is peculiarly viscid, much smaller in quantity, and excreted with great difficulty and laborious breathing, and the general symptoms evince great torpor of the extreme vessels of the lungs, the warmer and more pungent expectorants can alone be of any service, as the alliacea, and stimulant gum-resins, especially ammoniac, benzoin, styrax, and perhaps all the turpentine modifications.*

Tar-water was at one time a famous remedy; but has long fallen into great disesteem. From its warm terebinthinate impregnation, and the

* There is reason to think that the excessive use of tartar-emetac, as now adopted by some American practitioners, in not a few instances may prove detrimental. With Rasori and his disciples, fancy seems too frequently to have assumed the place of facts.—D.

† Expectorants are usually defined to be medicines which promote the excretion of mucus and fluids from the surface of the lungs and trachea. The reader will find an admirable chapter on the principles of their operation in Professor A. T. Thomson's *Elem. of Materia Medica*, vol. ii., p. 137.—Ed.

* In the chronic cough of old age, moderate bloodletting will often be useful: depletion in this way, and by mild aperients, followed by the use of stimulating expectorants, as the syrup of squills, &c., is not to be overlooked. Dr. Rush has well sustained the importance of occasional bloodletting in several varieties of this complaint; and the experience of the best clinical observers accords in the utility of this practice.—See Dr. Scudder's *Dissertation on the Diseases of Old Age*, New-York, 8vo., 1813.—D.

approach it makes to camphire and the gum-resins just enumerated, it may doubtless prove serviceable in many cases. It is for the same reason that the vapour of tar, exhaled from a tin pan with an oil or spirit-lamp beneath, as recommended by Sir Alexander Crichton in phthisis, is, in the present cough, frequently employed with advantage. The *acidum abietis*, another old preparation of the same kind, seems, however, to be the most deserving of trial of all the terebinthinate forms, and has sunk into disrepute without reason: it is the peculiar acid liquor, yielded along with the essential oil, in distillation of the fresh branches or fruit of the *pinus sylvestris* and *p. alba* of Linnæus. It is too acrid to be drunk alone, and is usually diluted with water: and combines in itself some portion of the terebinthinate-oil, with an acid very nearly resembling the acetous.

The same tribe of medicines will generally be found useful in the third variety, or that in which the cough is followed by a thin, frothy, and saline excretion; for here we meet with as much local atony and torpor of the excretories as in the preceding. We may here also with advantage employ several of the narcotic bitters, and especially the hop, in the form of pills or tincture; and occasionally the narcotics themselves, as opium, or hyoscyamus, or the extract of the common potato, *solanum tuberosum*, as recommended by Dr. Latham.—(*Med. Trans.*, vol. vi., art. 6.) But where the cough is dependant upon morbid affection of some remote organ, and the lungs are only influenced by sympathy, as is often the case in chronic hepatitis, it is obvious that our chief attention should be directed to the primary disease.

In the nervous or periodic cough, narcotics should be employed very cautiously, and only where the irritation is perpetual, or otherwise unconquerable; demulcents will also be of no service. Though the warmer expectorants may be useful, our chief dependance must be on general tonics, as the columbo, cusparia, and cinchona, with which may be combined several of the metallic oxides, especially those of bismuth and zinc. When the flowers of zinc were in the height of their popularity, they were supposed to be an unfailing remedy; and Dr. Percival, of Manchester, has given numerous examples of their complete success. By having been too highly advocated, this medicine has now fallen into an undue degree of disesteem. Camphire and ammonia will often prove palliatives for the cough, and may be occasionally had resort to; but moderate exercise and change of air should uniformly make a part of the tonic plan, wherever the patient's means will allow.

In this modification of cough, more than in any other, we have reason also to expect benefit from a cautious employment of the prussic acid,

* *Recherches Physiologiques et Cliniques sur l'emploi de l'Acide Prussique ou Hydro-cyanique, dans le Traitement des Maladies de Poitrine, &c. Par F. Magendie, &c., 8vo., Paris, 1819.* Under the name of *spasmodic cough*, Dr. Elliotson refers to a cough that comes on in long and violent paroxysms, and occurs in adult subjects: if united

which has the peculiar power of diminishing the general sensibility, without affecting the functions of respiration or circulation. Of all the cases published by Magendie and Brera, in proof of its beneficial qualities, none are so decisive as those of chronic and nervous coughs.* Six drops of the acid, prepared according to Scheele's method, may be given in a wineglass of infusion of cusparia every four hours.

SPECIES II.

BEX SICCA.

DRY COUGH.

COUGH UNACCOMPANIED WITH EXPECTORATION.

The symptom in the definition sufficiently shows that the seat of the disease is here, either in a remote organ or in the parenchyma, or general substance of the lungs, rather than in the mucous membrane of the bronchiæ. The disease is commonly, indeed, produced by some irritable substance generated within the lungs, as in the case of a scirrhus or calcareous affection of these organs; or conveyed into them from without, as is common to glasscutters, hewers of freestone or sandstone, workers of metals, and similar mechanics, in consequence of the finer particles of the materials on which they operate, being occasionally inhaled with the inspired air, and afterward making their way through the delicate tunics of the air-cells.

The dry cough is also at times to be traced to a remote irritation, as that of worms, or an inflammatory action in the intestines, liver, or other abdominal organs: in most cases, the lungs themselves are probably quite passive, and only yield to the propulsive action of the diaphragm, and its auxiliary muscles, to which the remote stimulus seems to confine its sympathetic power.

The minute and invisible eggs of various insects floating in the atmosphere, are also sometimes swallowed in like manner, and in a few instances hatched into larvæ, which have been thrown up by the coughing.—(*Bartholin. Act. Hafn.*, iv., obs. 46.) Minute pieces of bone, and the kernels of cherries and other fruits, have, moreover, occasionally slipped into the trachea accidentally; and, after exciting great irritation, and a hard dry cough for a considerable period of time, have ultimately been thrown up. A bean, in this manner, dropped into the trachea, was rejected on the fifth day in a violent fit of coughing.—(*Beaussier de la Bonchardiere, Journ. de Med.*, xlv., p. 267.) It is more extraordinary that materials, introduced into or engendered in wounds in the thorax, should at times be found to work their way into the bronchial vessels, and in like manner be thrown up by coughing. Yet in this way have been discharged surgical tents that have slipped beyond

with inflammation, it is out of all proportion to it. In this disease, he has found the carbonate of iron the best remedy, sometimes preceded by bleeding, if the patient be robust.—(*Lect. at London University.*) The carbonate of iron might be tried in the chronic cough of elderly persons.—Ed.

the lips of the wound ;* and the splinter of a fractured rib.†

The varieties chiefly worthy of notice are the three following :

- a *Ingenerata*. From irritation produced locally, as a scrofulous, scirrhus, or calculous affection of the lungs.
- β *Extranea*. From irritating materials inhaled from without, as in various operations on glass, metals, sandstone, and marble.‡
- γ *Vermisosa*. From some remote irritation, chiefly that of worms burrowing in the intestines, liver, or other abdominal organ.

Of these, the LAST is only to be removed by removing the primary disease. It is most common to children, and has the associate signs of a tumid belly, and pale emaciated countenance. For the medical treatment we must therefore refer to the genus *HELMINTHIA*, in the preceding class.

When the irritation proceeds from a SCROFULOUS or CALCULOUS AFFECTION of the lungs themselves, our attention must be directed to the peculiar diathesis on which the disease is dependant. In the former case, small doses of the milder mercurial preparations, combined with the usual narcotics of the lurid and umbellate orders, as conium *Œnanthe* (dropwort), hyoscyamus, and solanum, may afford local relief by their narcotic and alterative power : while the general state of the system should be subjected to the regulations which will be found laid down under the diseases *STRUMA* and *MARASMUS Phthisis*, in the ensuing class.

The deposit of calcareous matter in the substance or air-cells of the lungs, may be the result of a morbid affection confined to the lungs themselves ; for we often find them loaded with a deposit of this kind, while all the other viscera are in a state of health ; or it may proceed from a calcareous diathesis, of which we shall have to treat more at large under the genus *OSTHETIA*, in Class VI., Order I., of the Nosological Arrangement. In the former case, acid inhalations, or fumigating the chamber with the vapour of tar, which always contains a portion of acid, after the manner proposed under the preceding species, will afford a prospect, not merely of temporary relief by their tendency to dissolve the calcareous deposit, but probably of more permanent benefit, by changing the nature of the morbid action.

Where the formation of calcareous matter appears to depend upon an osthetic diathesis,

or a constitution prone to generate lime, diluting apozems drunk freely will be serviceable ; and particularly a very free beverage of aerated mineral waters ; which, while they dilute, will tend to invigorate the system generally, and produce a beneficial change upon the habit. Where calculi are disposed to form in the kidneys or bladder, Dr. Russell has recommended a very liberal use of seawater ; De Haen of lime-water, of which he tells us, that in one case, not less than 1500 pints were drunk with very essential advantage. Many foreign physicians advise the continental mineral springs, as those of Pyrmont, Carolina, and Baréges : while other pathologists have found large quantities of pure water, hot or cold, prove as good a palliative or remedy : in all which, we trace out one common principle, which is that of dilution, and we can trace out nothing else. A warm climate, which proves a perpetual diaphoretic, and urges perpetually to the surface, will also in all probability be found serviceable ; and, above all things, pure air, and as brisk exercise as the patient can bear without fatigue, so as to strengthen the system, and at the same time keep the skin soft and moist.

Mechanics engaged in working on metals, glass, freestone, or any other material, minute particles of which are apt to fly about and impregnate the atmosphere, and pass by inhalation into the lungs, should be peculiarly careful to keep their mouths and nostrils covered with a handkerchief. And if the lungs be irritated with sharp spiculæ, and a distressing and chronic cough be excited, all similar labour must be abstained from ; the diet be peculiarly light ; emetics be frequently administered ; and, in the interval, diluting apozems be used copiously, with bland demulcents. And if, by these means, we can check the irritation for some weeks or months, the lungs will often, by a growing habit of exposure to its cause, cease to be materially affected by it ; and the patient may pass through life without much inconvenience. But if hereby we should not be able to succeed, inflammation, hemorrhage, or phthisis, will probably be the result.*

In this variety, we have also great reason to expect benefit from the use of mild expectorants and demulcents.

Of the nature and operation of expectorants I have spoken already : and as there is no com-

* Though various morbid affections of the lungs are imputed by Dr. Good, with many ancient and modern pathologists, to the inhalation of dust and other extraneous particles by several descriptions of workmen in their different employments, the correctness of the doctrine is denied by Professor Laennec (*On Diseases of the Chest*, &c. ed. 2, p. 137, transl. by Dr. Forbes), whose arguments, however, turn chiefly on the escape of some individuals from the mischief, though exposed to the suspected cause, and on the fact of dust taken into the lungs being expectorated afterward with the mucous secretion of the bronchiæ. Both these circumstances are true, and yet the temporary or partial lodgment of the extraneous matter may give rise in many instances to pulmonary disease. —ED.

plaint in which demulcents can be employed to more advantage, and few in which they will prove so pleasant and tranquillizing, let us digress for one moment to examine into their nature and operation.

Demulcents are medicines that obtund the action of acrid or spicular materials, not by changing their acrimony, but by covering them with a viscid and inirritant fluid. They are of two sorts, mucilaginous and oily; and of the manner in which they act, when applied to the surface of the body, there is no doubt whatever. But, by what means they are able to retain their inviscating power, when passing through the stomach to a remote organ, is far less clear, and has been a source of considerable controversy. Where the irritation is in the lungs, as in the case before us, it has been supposed by many writers, and especially by Dr. Cullen, that by swallowing these substances leisurely, as we necessarily besmear the fauces and upper part of the glottis, we directly take off all irritation from these organs: and that the quietism hereby produced in the upper extremity of the trachea, is propagated by sympathy through the whole of the bronchial ramifications and the air-cells of the lungs; and that it is in this manner demulcents prove remedial in all pulmonic irritations.

But this is no explanation of their obtunding power in remote quarters, as for instance in the kidneys and bladder, where these organs have been stimulated by a blistering plaster: and as Dr. Cullen is not willing to allow of a specific power in medicines of any kind, nothing has remained to him but to cut the Gordian knot abruptly, and to contend that "the operation of demulcents in covering acrimony in the mass of blood, must be very inconceivable."—(*Mat. Med.*, part ii., cap. xii., p. 412.)

But this is to uphold an hypothesis by an assertion, opposed to the experienced train of events, and to which he himself submits on other occasions; for Dr. Cullen has no hesitation in recommending the use of demulcents, when we follow him into his practice, almost as freely as any other physician whatever. I pretend not to determine whether they act in every instance when employed internally by their sensible quality of viscosity, or by some insensible specific power; but that, by some means or other, they are capable of allaying irritation in organs remote from the stomach, is a fact so generally known, that it would be a waste of words to bring examples of it. And notwithstanding the difficulty of conceiving how a few drachms of bland oil, or a few ounces of gumarabic, can be intermixed with many pounds of serosity, and still retain their sensible quality of inviscating sedatives, it is by no means more difficult to conceive this, than that moderate doses of sulphuric acid, introduced into the stomach, should pass copiously by the skin in its acid state, as Dr. Cullen allows it to do, and cure the itch; or that the muriate of soda, employed as an ingredient in the manufacture of glass, should, in the melting of this material, impregnate the atmosphere of the glasshouse, be inhaled by the lungs of the

workmen, and passing with the matter of perspiration through the pores of the skin, once more concrete in crystals on their foreheads.

As several of the vegetable oils are obtained from narcotic plants, it is well worth inquiring, though a different question, whether, in any of these, there is a combination of any portion of the narcotic principle; as such oils would in many cases possess a high advantage over the rest. The oils of this description which have been most tried, are those obtained from the seeds of the *lactuca virosa*, and the *papaver somniferum*: and both these kinds of seeds, while they make pleasant emulsions, are said by many writers to communicate a slight degree of narcotic power at the same time; an assertion, however, which Dr. Cullen does not give credit to, and which seems to be disproved by repeated trains of experiments in France, and especially by those of the society of agriculture in 1773, with respect to the former. But as I have not tried them sufficiently to speak with decision on the subject, I merely throw out the hint, that it may be followed up by others, and extended to plants not yet examined for this purpose. The seeds of both plants give forth oil pretty freely; those of the poppy often in the proportion of six or seven ounces of the oil to every two pounds of the seeds.

In hot weather, sultry climates, or long voyages, where rancidity may be apprehended, the best, as well as the pleasantest of all the vegetable oils, is the expressed oil of the cocoanut, commonly known by the name of BUTTER OF CHOCOLATE. It is of a brownish hue when first obtained, but may be whitened by abluion in hot water, and still more so by an alkaline ley, quicklime, or spirit of wine. It will keep for years without becoming rancid, and may even be left for a month in a copper vessel without undergoing this change.

Of the vegetable mucilages, the best fitted for keeping is that obtained from the Iceland moss. If infused in water before it is boiled, it will lose much of its rough bitterness and colouring material, and its taste will be pleasant. Its viscosity is more than double that of gumarabic; and emulsions, thus formed, have been kept fourteen weeks without the slightest marks of putrescence.

SPECIES III.

BEX CONVULSIVA.

HOOPING-COUGH. KIN-COUGH.

THE COUGH CONVULSIVE AND SUFFOCATIVE; ACCOMPANIED WITH A SHRILL REITERATED HOOP; AND FREQUENTLY WITH VOMITING; CONTAGIOUS.

THE Greeks denominated this disease *Bex theriodes* (Βηθηριδης), which the Latins translated literally *Tussis ferina*, "wild or untameable cough," from its violence. The name of Pertussis, by which it has often been called in later times, is of doubtful origin and meaning; and I have hence followed M. de Sauvages and exchanged it for *Tussis convulsiva*, the specific epithet being far more expressive than that of

the Greek writers. Our own name of Hooping-cough is evidently derived from the convulsive clangour which accompanies the fit. The name of *Kind-cough*, by which it is distinguished in the north, and which should rather be written *Kind-cough*, is derived from the Saxon or German term *Kind*, "a child," as being peculiarly common to this age. This cough is contagious, though not in a very high degree; whence Stoll and other writers have fallen into the error of asserting, that it is not so at all.* [Even Laennec (Op. cit., p. 96) deems the contagious nature of hooping-cough not satisfactorily proved, and regards alternation of temperature quite as much a cause of this as of other catarrhs.]

The remote cause of hooping-cough is often difficult to trace. Frequently, indeed, like common or humid cough, it seems to proceed from cold, from some irritability of the stomach (*Allgem. Deutsche Bibl.*, lvii., p. 434), or some peculiar affection of the lungs.—(*Stoll, Prælect.*, p. 289.) I have already observed, that the dry cough (*tussis sicca*) has occasionally been produced by larvæ of insects, whose minute eggs, being inhaled with the air of respiration, have found a convenient nidus in the bronchial vessels; and hence Linnæus, who at one period of his life endeavoured to resolve almost all diseases whatever into an animalcular or insect origin, taught that the hooping-cough was also produced in the same way by an insect of a peculiar kind.—(*Amæn. Acad.*, vol. v., p. 82.) This opinion has not been adopted beyond the precincts of the Linnæan school. But we are, nevertheless, very considerably in the dark upon the subject; for there are numerous cases of the disease occurring daily in which it originates from a source that eludes our research altogether. It is most common to children, though sometimes to be met with in adults; is often epidemic; but rarely, if ever, attacks more than once in a man's life. And from all these circumstances, it may be inferred that it proceeds, in most instances, from a miasm of a specific nature and peculiar quality; which, like those of the influenza or epidemic catarrh, and the measles, has a direct determination to the lungs; though it is not, like these contagions, essentially linked with fever.

The excretion is at first small in quantity, but afterward more copious, though always viscid. The hoop, or sonorous spasm, is often accompanied with a rejection of the contents of the stomach;† and the whole system, during the

paroxysm, suffers great violence. The face is turgid and purple from suffusion, and the eyeballs swollen and prominent. The little patient, with a forewarning of the attack, falls on his knees at the time, or clings closely to any thing near him. Yet the violence is instantly forgotten; and, after deeply panting for breath, he returns with as much eagerness as ever to his play, or other pursuit: while the vomiting, which is commonly a good sign, is succeeded by a craving for fresh food. [In the words of Laennec, a colourless, and scarcely frothy, but ropy phlegm, rather flows than is rejected from the mouth, after each paroxysm, while the patient leans forward to favour its escape. The paroxysms at first recur several times every day, being almost always most severe towards the evening, but less violent in the night. After a certain time, they return only in the morning and evening, and towards the end of the disease, in the evening only. Before it terminates the paroxysms are shorter, lose their peculiar characters, and are attended with an expectoration more decidedly mucous. Sometimes the disease degenerates into a chronic mucous catarrh, with emaciation, and other symptoms resembling those of consumption. In the interval of the paroxysms, the patient coughs but little, and though Drs. Cullen and Watt represent some slight febrile indisposition as being mostly observable at certain periods of the day, Laennec states, that the patient rarely has any fever, except in the case just now mentioned, or at the beginning of a very severe attack.*]

lent a cough as the rest.—Elliotson's Lectures, Med. Gaz. for 1832-3, p. 194.

* See Laennec on Diseases of the Chest, &c., transl. by Forbes, p. 96, ed. 2, 8vo., Lond., 1827. As bronchitis is not an infrequent complication of hooping-cough, especially of the most dangerous forms of it, febrile symptoms must occasionally attend the disorder. Dr. C. Johnson distinguishes four states of hooping-cough: 1. Simple hooping-cough. 2. Hooping-cough complicated with bronchitis, or peripneumony. 3. Complicated with disordered bowels, or infantile remittent fever. 4. With convulsions, or hydrocephalus. The latter ought, perhaps, to have made two varieties. We see then that the disease is liable to be combined with infantile remittent fever, as well as the common sympathetic fever of inflammation. A great number of the long-protracted cases are complicated with remittent fever, which sometimes begins with a rigour, but more frequently comes on so gradually, that the date of its commencement cannot be fixed. "The paroxysms of coughing become more frequent, and the breathing is quickened and oppressed; but still it may be, with a little care, distinguished from the attack of bronchial inflammation. The stethoscope affords us useful though negative evidence. The usual symptoms of bronchial inflammation are absent. The frequency and force of the respiration are increased; but this increase is not accompanied by any râle, indicative of bronchial inflammation; while the daily remissions, the loaded tongue, the nature of the alvine discharges, the aspect of the child, constantly picking his nose and lips, all serve to determine the true character of the disease."—Cyclop. of Pract. Med., art. HOOPING-COUGH, by Dr. C. Johnson.—Ed.

* Rat. Med., part ii., p. 184. It is not an uncommon belief, and it was adopted by Cullen, that hooping-cough is not contagious beyond a month or six weeks from its commencement, just as is the case with some other contagious diseases, as for instance gonorrhœa, though, as Dr. Elliotson well observes, nobody will venture to fix the period of the commencement of its innoxious character.—Lect., Med. Gaz., 1832-33, p. 194.

† When the child vomits, it is generally considered a good sign: if there be no vomiting, the case is often found to be very severe. Dr. Gregory knew a lady who never hooped in the disease, but, instead of doing so, always fainted. The disease prevailed in the family, and she had as vio-

The disease lasts irregularly from three weeks to as many months.

[Each fit is composed of a quick succession of sonorous coughs, with scarcely any perceptible intervening inspirations, except that, from time to time, the expirations of coughing are suddenly interrupted by a very deep, seemingly convulsive, and noisy inspiration, accompanied by a lengthened hissing, that constitutes the pathognomonic sign of the disease. Laennec represents the peculiar sonorous inspiration as seated exclusively in the larynx and trachea. He also considers the spasmodic character of the whooping-cough as sufficiently proved by certain phenomena, which occasionally show themselves in the glottis, larynx, and even in the pendulous veil of the palate. The extraordinary noises made by certain patients in breathing, or coughing, he imputes to a spasmodic or voluntary contraction of these parts. The same, he says, is true of the peculiar sounds which attend the whooping-cough. He has seen patients who crowed like a cock, or barked like a dog. Dr. Bally sent him a patient with whooping-cough, in whom the paroxysms were accompanied with a cooing, like that of a woodpigeon. Laennec was convinced by observation, and the aid of the stethoscope, that the sound arose from a spasmodic contraction of the veil of the palate and sides of the glottis. The opinion was further confirmed, by the suspension of the sound by an accidental inflammation of the throat, and its renewal, in a less degree, on the subsidence of the latter complaint.—(Op. cit., ed. 2, p. 96–98.)]

The whooping-cough, when in the height of its career, is usually accompanied with very copious secretion of mucus, a free discharge of which mitigates the general symptoms. From this circumstance Dr. Butter concludes, that a morbid irritability of the mucous glands is the primary affection, to which the spasms are only secondary.—(*Treatise on the Kin-cough*, with an Appendix, &c., 8vo.) It is somewhat singular, that, with this view of the disease, he should place its seat, not in the larynx, or any part of the trachea, but in the alimentary canal. In infants, it is mostly alarming from its tendency to produce convulsions, suffocation, apoplexy, inflammation of the brain, ruptures, and incurvation of the spine. [The younger the subject, the more dangerous the disorder generally; and the large majority of those who die from its attacks, are observed to be under two years of age. Children born of phthisical, asthmatic parents, are most likely to suffer from the violence of the disease. Yet it is said that a healthy child under six months, who has a good nurse, will get through the disease better than one a few months older, who has been recently weaned, or in whom dentition has commenced. The following circumstances are also enumerated by Dr. C. Johnson, as justifying a favourable prognosis: dentition being completed, and the head, bowels, and lungs not being subject to determinations or irritations; the season of the year being mild and dry; the patient not suffering, or not having recently suffered from any of the other diseases of childhood, and having a sound healthy

constitution; finally, the accessions being at long intervals, the remissions complete, and the night, during which the symptoms are usually most severe, well spent. In adults, the prognosis is more favourable than in infants.] In adults, it excites pneumonitis more frequently than in children; and, in pregnant women, has often led to abortion. A moist skin, warm extremities, open bowels, plentiful expectoration, and free vomiting, are favourable symptoms. Frequent hemorrhage protracts the disease; and if it proceed from the lungs, a foundation will often be laid for phthisis. The violence of the action occasionally excites inflammation in the trachea. Dr. Marcus, among other singular opinions that distinguished his career, brought himself at last to believe, that such inflammation was always present: and having advanced thus far, he next undertook to show that whooping-cough and croup are one and the same disease. He died, indeed, while dictating the preface to his treatise on the former affection, which he hoped would establish this opinion. Dr. Dawson has since revived a part of this hypothesis, by conceiving that whooping-cough is a specific inflammation, seated in the glottis, or upper part of the trachea, and spreading more or less widely, according to the degree of its violence: but he does not identify it with croup.—(*Nosological Practice of Physic*, 8vo., 1824.)

[Dr. Watt inculcated the opinion, that whooping-cough is essentially an inflammation of the mucous membrane of the bronchiæ, which statement agrees with Laennec's description; and, if correct, the complaint should properly be regarded, with Laennec, as a species of catarrh, and classed accordingly. The disease, when fatal, generally becomes so from severe bronchitis. In several instances, in which the state of the lungs was ascertained by dissection after death, the most remarkable appearances were an inflamed condition of the trachea and bronchiæ, particularly of the latter, and an almost complete obstruction of the bronchial passages with a serous or mucous fluid, interspersed with flakes of semipurulent matter.—(*Treatise on Chin-cough*, &c., p. 123, 8vo., 1813.) These effects may be supposed to be only the consequence of the violent cough; but as Dr. Forbes has remarked, the opinion, delivered on the seat of the complaint by Dr. Watt, is amply confirmed by the early symptoms, and the indications of the stethoscope.*]

* Note in transl. of Laennec on Diseases of the Chest, &c., p. 98, ed. 2. In the greater number of cases where children die, says Dr. Eliotson, there is a violent bronchitis, sometimes combined with an extensive inflammation of the substance of the lungs. But he adds, that, on opening children who have died of this disease, you sometimes find very little the matter with the lungs, and death may have arisen from some other cause; for the disease has a great tendency to produce hydrocephalus and convulsions. When the air-cells inflame, and the lungs become more or less hepatized, the silvery rattle may be heard with the stethoscope, and the breathing is excessively loud and rough throughout the chest.—(Lect. at Lond. Univ.—See Med. Gaz. for 1832–3, p. 194.) The

In a few rare instances, whooping-cough assumes a periodic character, and is then sure to become peculiarly intractable. Dr. Perceval, in his *Comments on the Nosology*, has favoured me with a singular case of this kind, which occurred daily at a certain hour, attended with a tremor of the whole body : the fit terminating by a shriek, rather than a hoop. The complaint was obstinate for several months, and returned at the same season for two years. It yielded to no medicine, and was supposed to depend on some morbid condition of the liver.

[Notwithstanding the contrary statements sometimes made, Dr. C. Johnson believes that the whooping-cough rarely, if ever, affects the same individual twice ; and that it is seldom met with in adults, of which, however, instances are upon record.]

Dr. Cullen, in laying down his own mode of treatment, indulges in an ingenious, and I believe correct hypothesis, and divides the disease into two stages. The first consists of that part of it during which he supposes the contagion to be present and operative, which possibly may include the first three weeks ; the second embraces the remainder of its duration. Throughout the former stage, our attention should be directed to whatever will moderate the influence of the contagious stimulus, retard the return of the convulsive paroxysms, and mitigate their violence. [If the patient can be made to drink by small and repeated portions during the paroxysm, its severity and duration, according to Laennec (*Op. cit.*, p. 98), will be diminished ; perhaps from the effort of deglutition facilitating deeper inspirations, by counteracting the spasms of the bronchiæ.] Bleeding, in severe cases, will usually be found necessary for this purpose ; but it should be avoided under other circumstances ; and it will generally be found better to employ blisters as a substitute. The most effectual remedy is emetics ; whose action tends equally to interrupt the return of the paroxysms, and to keep the lungs unloaded, by producing a determination towards the surface. [Laennec recommends them to be repeated every day, or every second day, for a week or a fortnight ; and prefers tartarized antimony to ipecacuanha, on account of the great inequality of power in the latter, and the solubility of the former allowing it to be more easily administered in doses proportioned to the exigency of the case.] The food must be light, and costiveness carefully prevented ; but no benefit seems to be derived from purging.*

danger is in proportion to the affection of the head, the bronchitis, and the peripneumonia.—Ed.

* A better founded division of whooping-cough is into the inflammatory and merely spasmodic forms. If there should be a constant oppression of the breathing, with spasmodic attacks, and a violent cough at times, an accelerated pulse, and a sonorous, sibilous, and crepitous rattle, there is inflammation of the bronchiæ, or the substance of the lungs. Here, as Dr. Elliotson properly remarks, you might give all the antispasmodics, all the narcotics, and all the medicines that are supposed to have a direct influence over spasm, and yet do no good. If the patient be old enough, he must be

In this manner, upon Dr. Cullen's mode of treatment, we are to guide the patient through that part of the disease which we may suppose to be kept up by the stimulus of contagion. In its latter part, or second stage, in which a morbid habit alone is, in all probability, the irritative power, a different course is demanded. For we have now nothing more to do, than to oppose the spasmodic habit by an antispasmodic process ; and hence different tribes of medicines have been resorted to, which may be arranged under the three divisions—of SEDATIVES, for the purpose of taking off the morbid irritability of the affected muscles ; STIMULANTS, for the purpose of local or general revulsion ; and TONICS, for that of both local and general reinvigoration.

The sedatives chiefly recommended, have been opium, hyoscyamus, belladonna, conium, musk, and the hydrocyanic acid.

Though opium has the authority of many distinguished practitioners (*Hufeland, N. Annalen*, i., p. 367 ; *Demachy, Manuel de Pharmacie*, Paris, 1788 ; *Rüling, Beobachtung der Stat. Northeim.*, p. 107), it has often been found of no avail, even where it has been given in large and frequent doses ; and, still more generally, it has been productive of greater mischief than good. The compound powder of ipecacuanha is one of the best preparations of opium which can be employed in this disorder. The conium has acquired a far higher degree of public favour, for which it is much indebted to the writings of Dr. Butler, who represents it as having the double virtue of retarding the returns of the convulsive paroxysms, and of mitigating their violence ; and on this account, he prescribed it through every stage of the disease, and however complicated with other affections. He employed it, moreover, in every form, whether of powder, extract, plaster, or cataplasm ; but, for internal use, he gave the powder, allotting a grain a day to infants under six months, and ten grains to adults, with a gradual increase as they persevered. [After emetics, Laennec also prescribes narcotics in small doses, and considers the extract and powder of belladonna as the best medicine of this class. The dose is from $\frac{1}{4}$ to $\frac{1}{2}$ of a grain. Its efficacy in lessening the severity of the cough, and shortening the duration of the disease, he conceives, may be accounted for by its lessening the necessity of respiration, and consequently the dyspnoea ; obviating the spasm of the bronchiæ ; diminishing the irritation produced by the vascular congestion of the mucous membrane ; and lessening the augmented secretion.]

bled occasionally in the arm ; leeches should be applied to the chest, and mercury and emetics exhibited. " In the greater number of cases, the inflammation is such as will yield to the application of a few leeches and the exhibition of emetics ; but it is of great use likewise to clear out the bowels by calomel, provided the inflammation is severe, and to give it steadily in small and repeated doses." —(*Med. Gaz.*, loc. cit.) Dr. Elliotson is also an advocate for the warm bath, and for not letting children with this disease overload the stomach, or move or run about a great deal ; circumstances always aggravating the cough, and the bronchitis, if any degree of it be present.—Ed.

Musk has been tried both abroad and at home, from six grains to half a drachm at a time; but its effects are so various, and, indeed, contradictory in different individuals, as to prevent confidence in its use.

The prussic or hydrocyanic acid has unquestionably subdued the spasmodic irritation, and consequently relieved the cough, in a variety of instances. It is here, indeed, and in nervous cough, that it seems to act with most advantage.—(*Recherches Physiol. et Clin. sur l'Emploi de l'Ac. Prussique, &c., par N. Magendie, D. M., Paris, 1819.*) I have known it succeed when there was the utmost degree of danger from general convulsions; the dose for a child of four years old being from a drop to a drop and a half, or even two drops of Scheele's preparation of the acid, every four hours, till a decided impression is produced.*

The stimulant plan, if it have not been more successful than the sedative, has at least been as powerfully supported. Its intention I have already stated to be that of taking off the propensity to spasmodic action in the trachea, by exciting a general or remote local revulsion. And the medicines chiefly employed for this purpose, have been cantharides, ammonia, ether, camphire, the herb Paris, and rhus Vernix.

[Laennec has seldom found blisters of much use: instead of them, Autenrieth has proposed the application of tartar emetic ointment to the chest, a plan, from which more benefit has sometimes resulted than from blisters.]

When blisters were formerly employed with great freedom in the whooping-cough, it was thought to be ascertained, that they always answered best when they irritated the bladder and occasioned strangury. And, on this account, some practitioners have endeavoured to produce the latter effect without the pain of the former, and have for this purpose employed cantharides in tincture, in the proportion of twenty minims to a dose.—(*Forbes, loc. cit.*) Dr. Barton of York first joined it with bark and the compound tincture of camphire, a practice afterward adopted by Dr. Lettsom, Hufeland, and others. But whether given alone or in combination, I have never found any decided benefit from its use.

Where the intention is to divert the tendency to convulsive action by local revellents, it is far better to employ them externally, and particularly on the chest, and down the chain of the spine. The most common stimulants for this purpose are camphire, ammonia, ether, and the essential oils of amber and turpentine, which, in different combinations, have been long used, and still preserve their reputation.

I have reason to believe that embrocations of this kind have often proved highly beneficial: and it is not difficult to account for such an ef-

fect: since the cervical and dors l nerves are so generally distributed over the muscles of the chest, the diaphragm, and the scapulæ; and some of them, as the accessory nerves of Willis, form an integral part of the par vagum, and assist in giving rise to the cardiac and pulmonic plexus.*

Many stimulants have also been occasionally employed internally for the purpose of producing an excitement generally, and thus of acting as universal revellents; as camphire, ammonia, and the sulphuric and nitric ethers. These have often been found useful, and, where narcotics are given, they rather assist than oppose their good effect.

[Dr. Andrews (*Glasgow Med. Journ.*, vol. i., p. 178) prescribed the tincture of lobelia inflata† with striking success. He says that there is no other medicine that so effectually frees the bronchial vessels of their viscid secretion. It is emetic and antispasmodic. The dose generally given by him was thirty or forty minims, every twenty minutes.]

The *rhus vernix* comes also strongly recommended by many foreign writers of distinguished character, as a stimulant and antispasmodic of considerable power, and highly useful in the whooping-cough. Dr. Fresnoi, to whom we are chiefly indebted for our acquaintance with it, employed its leaves in the form of an extract. Of this he dissolved four grains in four ounces of sirup, and gave a table-spoonful every three hours to a child.

[By Dr. Millar, a high opinion was entertained of asafetida, as a remedy for whooping-cough, as well as asthma.]

After all, if no bronchitis exists, perhaps the best antispasmodics are tonic medicines, and a tonic regimen. Dr. Cullen trusts almost exclusively to the cinchona: "I consider," says he, "the use of this medicine as the most certain means of curing the disease in its second stage; and when there has been little fever present, and a sufficient quantity of the bark has been given, it has seldom failed of soon putting an end to the disease."

The best and most convenient form of the bark for children is the sulphate of quinine. [It is observed by Laennec, that, when the paroxysms of whooping-cough assume a periodical type, cinchona, and the sulphate of quinine, are as efficacious as in cases of ague.] When the sulphate of quinine disagrees, as it will sometimes do, I have employed the mineral tonics, as the oxyde of zinc, from half a grain to a grain, two or three times a day; or the nitrate of silver, from the twelfth to the eighth part of a grain, repeated in the same manner.

[Dr. Elliotson considers the preparations of iron as the best tonics which can be employed

* If the child be young, Dr. Elliotson recommends one minim to be put in an ounce or two of almond emulsion, one teaspoonful of which, he says, will be the proper dose, three or four times a day.—Ed.

* The inhalation of tar fumes, sometimes recommended, is only allowable when no inflammation is present.—See Elliotson, *Med. Gaz.*, 1832-3, p. 196.—Ed.

† This medicine is highly recommended by Dr. Thatcher also. See *Am. Modern Practice of Physic*, Boston, 8vo., p. 248. See also Barton's *Veg. Mat. Med. of the U. States*, vol. i., p. 127.—D

in cases of whooping-cough, where no occasion for antiphlogistic treatment exists. The sulphate can be conveniently given to children in mixtures, or the carbonate blended with treacle.]

As an important part of our tonic plan, may be mentioned change of air, and especially where the difference of temperament, or even temperature, can be rendered very considerable, as from a low to a high atmosphere, or from the interior of a country to the seacoast; but cold-bathing, so far as my own experience extends, has proved more certainly and rapidly remedial, than any other prescription whatever; and particularly where it has never been made use of before, and hence introduces a new action into the system.*

* The diversity of views presented in the text concerning the nature and treatment of whooping-cough, seems to demand a word from the American editor. It is a truth painfully familiar to every observer, that, in our country, death by whooping-cough is not uncommon. The disease may fairly be considered as arising from a specific cause: of a contagious character, and as affecting adults of an advanced age as well as infants a few months old. "I have seen the disorder," says Dr. Francis, "sometimes occurring in children of some six or eight months of age, and but recently it proved fatal to an adult in his 82d year; nor does the system always enjoy an immunity from a second attack." From the circumstances which accompany it, it may be deemed occasionally of a spasmodic character, without inflammation; but in most cases, it must be classed strictly among the phlogistica: it involves the glottis, and the mucous lining of the bronchiæ is primarily affected with inflammation. The characteristics of spasm which so generally marks it, is doubtless attendant upon the peculiar seat of the inflammation; and this principle is illustrated also by the phenomena which croup often exhibits. A practical writer of eminence, Dr. Eberle, in speaking of the pathology of whooping-cough, remarks, "It appears to me that whooping-cough is essentially a spasmodic or nervous affection, the proximate cause of which consists principally in a peculiar irritation of the eighth pair, or the pneumogastric nerves."—(*Practice of Medicine*, vol. ii., p. 229.) This opinion has been advanced by several German writers; post-mortem examinations, however, of bodies dead by whooping-cough, often present various and opposite conditions, and some doubtless which have no connexion with the disease. A late writer, Desruelles, maintains that it is a bronchitis, which in its progress becomes complicated with cerebral irritation and congestion; that this encephalic irritation assumes an intermittent form, and is the primary organic cause of the convulsive cough which characterizes the disease. He therefore proposes to designate the disorder by the term, broncho-cephalitis.—(*North Am. Med. and Surg. Journal*, vol. ii., p. 156.) Inasmuch as there is a predominant tendency in this complaint to congestion of the brain and hydrocephalus, this name is not without its practical advantages. If whooping-cough be neglected, or badly treated, without reference to its acute character, it terminates so frequently in hydrocephalus, that the physician cannot be too mindful of this serious result. "Whooping-cough," says another distinguished American writer, "like catarrh, divides itself into two stages: the first febrile or inflammatory, to be treated by bloodletting, emetics, small doses of antimony, abstinence, and

VOL. I.—S

[The extract of common daffodil (*narcissus pseudo-narcissus*), and the infusion of its petals, were proposed, a few years ago, as a specific against this disease. Laennec, who tried the extract, found it, however, much less efficacious than belladonna. The dose is half a grain, a grain, or two grains, every two, four, or six hours, according to the patient's strength. Its mode of action is imperfectly known.*]

GENUS II.

LARYNGISMUS.

LARYNGIC SUFFOCATION.

SENSE OF SPASMODIC SUFFOCATION IN THE LARYNX, COMMENCING SUDDENLY, AND RELAXING, OR INTERMITTING; COUGH TROUBLESOME; SCANTY DISCHARGE OF VISCID MUCUS.

THERE is a disease that often attacks the larynx, and especially of infants and children, which has so near a resemblance to croup, as to be very generally confounded with it, and which is hence commonly known by the name of *spasmodic croup*: but which, notwithstanding the resemblance of many of its symptoms, is essentially different from it, and ought to be arranged in a different place. It is for this purpose the present genus has been formed, and the present name invented, with a termination that sufficiently distinguishes it from laryngitis, or inflammation of the larynx, yet a termination that has the sanction of the best medical writers in every age.—(*See Prelim. Diss. to the Author's System of Nosology.*) The distinctive characters of bronchlenmitis, or

the usual means constituting the antiphlogistic treatment. The second or passive stage, like the chronic state of catarrh, is frequently of long duration, and continued by the sensibility of the lungs attendant upon weakness. Exercise, change of air, stimuli, in the form of food and medicine, the external application of various embrocations, with the occasional use of vitriolic emetics, Mosely's solution, or the fashionable antiperussians, are now indicated. I have also oftentimes given the combination of the tincture of bark and cantharides, as recommended by Dr. Lettson, with the best effects.—(*Hosack's Essays*, vol. ii., p. 459. After suitable depletory means have been adopted, corresponding to the activity of the disease, emetics are among our most valuable remedies. Ipecacuanha is often efficient, and is generally a safe article: in this state of the disorder, however, Dr. Francis advocates a free use of the vitriolic emetics, particularly of the sulphate of zinc; "they have the advantage," he says, "of not adding to the debility of the sufferer, and relieve promptly and efficiently by ejecting the overloaded excretion of the bronchial vessels, and by harmonizing the disturbed and oppressed respiration." Our remedies may control the violence of whooping-cough, and safely modify its course; but except in cases purely spasmodic, can have but little influence in cutting short its duration.—D.

* When whooping-cough is complicated with infantile remittent fever, depending on constipation, or on derangement of the abdominal secretions, purgatives and alteratives are called for; especially, in the former case, calomel, rhubarb, and scammony; and in the latter, rhubarb and carbonate of soda, or the hydrarg. cum creta, or Dover's powder, followed by castor-oil.—Ed.

croup, are, inflammation of the mucous membrane of the trachea and bronchial vessels, and the secretion of a peculiar concrete and membrane-like material that lines the tracheal tubes, and threatens suffocation by obstructing them. In the disease before us, we have neither inflammation nor membrane-like secretion; while the sense of suffocation is produced, not by obstruction, but by spasm. The only known species belonging to this genus is the following.

SPECIES.

LARYNGISMUS STRIDULOUS.

STRIDULOUS CONSTRICTION OF THE LARYNX.

COMMENCING USUALLY IN THE NIGHT; VOICE SHRILL AND CROAKING; COUNTENANCE FLUSHED AND SWOLLEN; DISTRESSING STRUGGLE FOR BREATH.

THIS species forms the spasmodic asthma of Millar, Parr, and various other writers. Yet it is not strictly an asthma, though it makes an approach to it; and the name under which it has been thus described, shows sufficiently that the present is the proper place for its reception. In asthma, the constriction begins in the chest, and chiefly exerts itself there, though the spasm may extend to the upper part of the trachea. In spasmodic laryngismus the constriction commences in the larynx, and is chiefly confined to that organ, though it may extend to the chest. In the former, the respiration is wheezy, but the voice is not stridulous; in the latter, the voice is stridulous, but the respiration is rarely wheezy, or seldom so in an equal degree; evidently showing a difference in the seat of the two diseases. And hence I have found it necessary to separate it from asthma, and arrange it under a different head.

As already observed, the general symptoms make a nearer approach to croup. "The inconvenience," observes Dr. Parr, "is the greater, since, from the resemblance of the symptoms, remedies have been celebrated as successful in croup which were never used in the disease; and the less experienced practitioner, trusting to them, has felt the severest disappointment."

The suddenness with which this complaint commences its attack, forms another mark of distinction between itself and croup, almost as pathognomonic as the absence of inflammation, and the peculiar secretion in the latter. There are instances, indeed, in which genuine croup has also commenced abruptly, but these are very rare; for it has usually the precursive symptoms of a slight cough and hoarseness for a day, and sometimes two days, as though the patient were labouring under a catarrh. In croup, also, the inflammation, when it has once taken effect, becomes a permanent cause of excitement, and the anxiety and struggle for breath continue, with little if any abatement, till the inflammation is subdued. In the disease before us, the spasm suddenly subsides in

a short time, though it may perhaps return in an hour, or half an hour, or even a few minutes; and, in the interval, the patient enjoys perfect ease, though the voice is rendered hoarse from the previous straining. Croup is, moreover, an exclusive disease of children; stridulous spasm of the larynx is sometimes found in adults. Those who have been dissatisfied with the name of spasmodic asthma, have, however, treated of it under the name of spasmodic croup, but merely because they have not known how else to distinguish it; for almost every one who has thus noticed it, has acknowledged that it is a different disease, and demands a different plan of cure.

The exciting causes are not always clear: cold and teething are the most common. It appears most frequently in relaxed and irritable habits, where, in truth, we should soonest expect a display of spasmodic action. As there is mostly some degree of cough, and always a secretion of a small portion of viscid mucus, and a croaking voice, there is indeed great reason for supposing some degree of local irritation; and it is on this account that I have preferred entering the disease here, to an arrangement of it under the fourth class, consisting of diseases that are purely and idiopathically nervous. It is possible, however, that some of these symptoms may be the result of the spasmodic struggle itself.

An active plan of treatment is imperiously demanded. Yet an antimonial emetic generally effects a cure as soon as it begins to operate, if employed early: but the diaphoresis which it excites should be maintained for some hours, by keeping the child in bed, and the use of diluents; which will be the most effectual means of preventing a return of the spasm. The bowels should also be excited by a purgative of calomel. And if the emetic do not prove sufficient, or the stricture should be renewed, laudanum should be exhibited according to the age of the patient, and a blister be applied to the throat. But bleeding, which is indispensable in croup, should here be avoided, as it will only add to the irritability. Those who regard this affection as an asthma, have strongly recommended the fetid antispasmodics, as asafoetida, both by the mouth and injections; but I have not found them successful.

Generally speaking, after the action of the emetic, the child falls into a deep and quiet sleep, and awakes with few remains of the complaint. Yet, if the spasm be not attacked at once, suffocation may soon follow. Those who have once laboured under it, are more susceptible of it than before; and the younger branches of some families seem much more predisposed to it than those of others.

This disease has been noticed by M. Bretonneau of Tours, and described under the name of *angina stridula*. It was mistaken occasionally for a peculiar form of *angina maligna*, which was then prevailing as a contagious disease, and in which the local inflammation, instead of producing ulcerations, threw off membranous or croupy exfoliations, and was accom-

panied with a croupy suffocation. But, in the case before us, there was no swelling of the lymphatic glands at the angle of the jaws; the tonsils and velum palati were free from redness or tumefaction, and no pain was complained of in the region of the larynx. While the attendants were about to apply leeches, and exhibit an emetic, the little patient fell into a refreshing sleep; a gentle moisture appeared on the skin, the cough became looser and little troublesome; and next morning the complaint was nothing more than a common cold, which required no further medical aid. M. Bretonneau regards this affection as only a simple œdematous tumefaction (une simple tumefaction œdémateuse) of the mucous folds in the ventricles of the larynx.—(*Des Infl. spéciales du Tissu Muq.*, &c. Par P. Bretonneau, Paris, 1826.)

GENUS III.

D Y S P N Œ A.*

ANHELATION.

PERMANENT DIFFICULTY OF BREATHING; WITH
A SENSE OF WEIGHT IN THE CHEST.

THERE has been no small perplexity felt by nosologists in arranging the various diseases which are chiefly characterized by irksome or distressful breathing. The lungs, like the stomach, maintain a close connexion with most of the functions of the body, and the organs which are instrumental to them; while the complaints affecting respiration that originate in the chest, run so frequently into each other, as to require the utmost nicety in drawing the line between what ought to be regarded as genera and what as species. There are three thoracic disorders that are peculiarly obnoxious to this remark; I mean those which among recent writers have been described under the names of dyspnœa, orthopnœa, and asthma. Celsus, following the Greek physicians, regards them as only modifications of the same malady, merely differing from each other in degree.

"Each," says he (*Medicinæ*, lib. iv., iv., 2), "consists in difficulty of breathing. When this

difficulty is moderate and unobstructive, it is called dyspnœa; when it is more vehement, so that the breathing is sonorous and wheezing, it constitutes asthma; and when it can only take place in an erect position, it is denominated orthopnœa. The first is usually a chronic affection, the latter two acute." Galen, on the contrary, treats of these diseases as distinct genera, and discusses them in remote positions.

The same diversity of view has occurred in modern times. Sir John Floyer and Dr. Bree have reduced the three divisions of Celsus to two, and have used the term *ASTHMA* as a generic name under which to arrange them. These two divisions are *CONTINUED ASTHMA*, and *CONVULSIVE, or PERIODIC ASTHMA* (*Inquiry into Disordered Respiration*, 5th edit., p. 231); the former being the *DYSPNŒA* of the Greek writers and of Celsus, and the latter uniting their *ASTHMA* and *ORTHOPNŒA*. I call these divisions rather than species, because Dr. Bree makes four subdivisions of the latter, derived from their supposed causes, and assigns the name of species to them when thus subdivided: though, if asthma be employed generically, it would perhaps be more consistent with the rules of classification to name the primary ramifications species; and the secondary, sub-species or varieties.

Almost all the continental writers make each affection a separate genus, as does Macbride among those of our own country. Cullen makes a genus of dyspnœa, as well as of asthma, but merges orthopnœa in the former; Dr. Parr and Dr. Young take as little notice of orthopnœa, and, with Celsus, reduce dyspnœa and asthma to the rank of species, under a genus which they denominate *anhelatio* or *pneusis*, which are a Latin and a Greek synonyme; the former of which is applied by Sauvages to an entire order.

Yet Dr. Cullen himself, in his First Lines, is untrue to his Nosology; for having in his earlier work arranged and defined dyspnœa as a distinct genus, in his later he expresses doubts whether under almost every modification, it is to be regarded otherwise than as a vicarious or symptomatic affection. On which account, probably, Dr. Crichton, though for the most part very

* Dyspnœa is generally only a symptom of disease. It is correctly observed by Dr. Williams, that as the elements or principal parts concerned in the function of respiration are three, namely, the blood, the respiratory machine, and the air, the causes of dyspnœa may arise from changes in any of these. Hence, in the consideration of this subject, he divides it, 1st, into derangements which interfere with the respiratory movements; 2dly, derangements which obstruct the passage of air to and from the pulmonary cells; 3dly, derangements in the pulmonary tissue, obstructing the action of the air on the blood. Dr. Williams conceives that the muscular act of inspiration is excited by a sensation arising from the presence of black blood in the lungs. The views adopted in the following passage should never be forgotten in the investigation of dyspnœa and asthma. "As the peculiar condition of the blood, which is called venous, is the immediate cause of the sensation of dyspnœa, so the blood being (if we may use the expression) *more venous* than usual, may give rise to the feeling of dyspnœa, without any derange-

ment of the respiratory apparatus. Of this nature is the dyspnœa arising from violent exercise, which ceases as soon as the flow of venous blood to the lungs becomes moderated by rest. Whether other processes, such as increased secretions, the digestion of blood, &c., be capable of producing the like effect, that is, of so changing the blood, that although the respiration be healthy, this fluid is arterialized with sufficient rapidity to prevent the feeling of dyspnœa, is uncertain: but the stethoscope teaches us, that the function of respiration is more active in some individuals than in others, and that there is also a difference in the same individual at different times." Dr. Williams then adverts to individuals whose lungs are defective from disease, and who experience dyspnœa after taking food, though not usually sufferers from this complaint at other times. "It is," says he, "through the blood rather than in any other way, that diseases of the heart sometimes give rise to dyspnœa; any impediment to the pulmonary circulation causing imperfection in the oxygenating process."—Cycl. of Pract. Med., art. *DYSPNŒA*.—ED.

scrupulous in adopting Dr. Cullen's views, has banished dyspnœa as well as orthopnœa from his catalogue, and has only retained asthma of the whole three. Dr. Wilson Philip seems to make little distinction in the use of the terms asthma and dyspnœa, for his habitual asthma and asthmatic dyspnœa are synonymous for the same disease, and run parallel with the present genus.—(*On Indigestion, &c.*, p. 377, 384, 4th edit., 8vo., Lond., 1824.)

There is, nevertheless, a distinctive character, which, if steadily adhered to, may easily settle the question, and designate the proper place to which each respectively belongs. The difficulty of breathing is sometimes permanent; and sometimes recurrent, with considerable intervals of perfect ease; and, where it is permanent, it is occasionally distinguished by sudden and irregular exacerbations. These characters are clear, and cannot well be mistaken; and it is upon these pathognomonic marks that the arrangement we are now about to pursue has been founded. Dyspnœa distinguishes the cases of permanent difficulty of breathing; asthma, those of the recurrent; and orthopnœa, the cases of permanent difficulty of breathing with irregular exacerbations. The first two, therefore, form distinct genera; the last is necessarily a peculiar species of dyspnœa, linking it very closely with asthma.

Thus bounded and distinguished, dyspnœa, as a genus, offers us the two following species:

1. Dyspnœa Chronica. Short Breath.
2. ——— Exacerbans. Exacerbating Anhelation.

SPECIES I.

DYSPNŒA CHRONICA.

SHORT BREATH.

THE BREATHING UNFORMALLY SHORT AND HEAVY;
MOSTLY ACCOMPANIED WITH A COUGH.

The causes of this complaint exist in the chest locally, or in the habit or constitution generally: they are inbred, or the result of accident; and hence the disease exhibits the following varieties:

- | | |
|---------------------|--|
| a Organica. | From organic deformity, |
| Organic dyspnœa. | oppression, or accidental injury. |
| β Extranea. | From calcareous or other |
| Extraneous dyspnœa. | spicular materials, inhaled while working on stones or metals. |
| γ Vaporosa. | From the mischievous |
| Mephitic dyspnœa. | action of metallic or other poisonous exhalations. |
| δ Phlegmatica. | From a phlegmatic or |
| Phlegmatic dyspnœa. | cachectic habit. |
| ε Pinguedinosa. | Accompanied with op- |
| Corpulent dyspnœa. | pressive fatness. |
| Pursiness. | |

When the chest labours under an ORGANIC DEFORMITY, or oppression, or the effects of an accidental injury, its cavity is contracted, and its motive powers are usually enfeebled, or cur-

tailed in their action. This is by far the most frequent variety under which the disease makes its appearance. In some instances, the lungs have been found peculiarly small (*Sandifort, Observat. Anat. Pathol.*) and shrivelled (*Bonnet. Sepulchr.*, lib. x., sect. i., obs. 45) in persons who have died of this complaint. [Laennec says, that they diminish in size only from the effects of external pressure, or in consequence of the growth of accidental productions within their substance, which may be considered as exerting a pressure from within outwards. This opinion he illustrates by a reference to what happens in cases of empyema and tubercles.—(*On Diseases of the Chest*, p. 147, 2d edit.)] The lungs are sometimes peculiarly hard, and cartilaginous in the duplicature of the pleura which surrounds them.—(*Schreiber, Nov. Comment. Petropol.*, iii., p. 395.) There has been adhesion between the folds of their membrane; or adhesion, sometimes ossification (*Schachier, Diss. de Ossificatione Præternaturali, Lips. 1726*), between the pleura and the ribs, sufficient to lay a foundation for difficulty of breathing. The lungs have been found loaded with hydatids, which have diminished their elasticity;* and sometimes these animalcules have been thrown up by coughing (*Ephem. Nat. Cur.*, dec. ii., ann. i., obs. 80); and still more frequently the lungs have been indurated by scirrhus, or oppressed with steatomatous, or other tumours.

In Bonet and other writers, we have also examples of internal oppression, and a diminution of cavity, produced by an excessive magnitude in the substance of the lungs, offering a sort of parabsma of this organ, so as to leave little room, and allow little elasticity for their proper play.† And still more generally the oppressive cause lies without, and the capacity of the chest is diminished by rickets, or a softness of the bones (*parostia flexilis*), or some accidental injury, by which the ribs or sternum have lost their proper form, and are become incurvated, and without a power of elevation.

In all these cases the healing art can do little. It may, perhaps, occasionally palliate some of the distress to which the patient is irrevocably doomed, but it cannot go further. Perfect tranquillity of body and mind, gentle exercise, a light diet, with a total abstinence from flatulent vegetables and fermented liquors, and an undeviating habit of regular hours, comprise, perhaps, the whole that can be recommended by the physician, or attempted by the patient. [Where dyspnœa depends on the presence of hydatids, or, as Laennec terms them, acephalocysts in the lungs, common salt appears most deserving of trial as a means of cure. Sheep which feed in salt meadows are exempt from

* Bonet. Sepulchr., lib. ii., sect. i., obs. 33. Also, valuable observations on this subject, by Laennec, p. 373, 2d edit.

† Sepulchr., lib. ii., sect. i., obs. 57, 58. Ruysch, obs. 19, 21. Eph. Nat. Cur., dec. i., ann. i., obs. 6. Id., dec. ii., ann. x., obs. 175; and Laennec on Diseases of the Chest, chap. on Hypertrophy of the Lungs, p. 146, 2d edit.

the rot and staggers, which are occasioned by the development of two species of vesicular worms in the abdominal viscera and brain. If attacked, a removal to such meadows generally cures them. Salt water baths have appeared to Laennec (Op. cit., p. 377) to benefit patients afflicted with analogous complaints. It is not necessary, he says, that the hydatids should be expelled, to effect a cure: it suffices if they be deprived of their vitality, after which their liquid is absorbed, the cyst shrinks into a small compass, and, upon cutting into the tumours, we find the hydatids quite flattened, and sometimes stratified with layers of albuminous and friable matter.]

Sawyers and hewers of freestone or other fossil masses; glass-cutters, china-manufacturers (See *Hastings on Infl. of the Mucous Membrane of the Lungs*, p. 273), lapidaries, and workers upon metals, are often subject to dyspnœa, from having the LUNGS LOADED WITH FINE PULVERULENT PARTICLES, detached from the materials on which they are employed, and floating in the atmosphere that surrounds them. And to these may be added, millers, starch-makers, horn and pearl-workers, needle, edge-tool, and gun-barrel grinders; and, for a like reason, weavers, wool-carders, and feather-dressers. This affection is so nearly similar to the variety β of *dry cough*, on which we have treated already, that it is only necessary to refer the reader to the remarks there laid down. The cause and mode of treatment are the same; and the symptoms chiefly differ from a difference of constitution. Where the lungs are peculiarly irritable, a troublesome cough will ensue from the first, before any considerable quantity of buoyant particles can have entered into the bronchiæ; but, where there is little irritability, no cough demanding particular attention has shown itself for years; and the lungs, from a habit of exposure to the same influence, have betrayed no uneasiness, till they have gradually been transformed into almost a mine or quarry of the material worked upon.—(*Hecquet, Maladies des Artisans*, tom. ii.) Various contrivances have been devised for straining off the floating particles from the air inhaled, and thus producing a preventive. Dr. Johnstone, long ago, proposed a muzzle of damp crape for this purpose; Dr. Gosse, a sponge; and M. D'Arcet an apparatus which he calls a fourneau d'appel: but, for workers in steel or iron, one of the most ingenious is a peculiar kind of magnet, that concentrates the metallic spiculæ, and thus prevents them from floating loose in the inspired air. It is an invention of Mr. Abrahams, of Sheffield, and has justly met with the approbation of the Society for the Encouragement of Arts.

[The doctrine of diseases of the lungs being produced by the inhalation of dust, and other extraneous particles, was considered by Laennec to be destitute of foundation. The dust, he observes, is quite dissimilar from the cretaceous formation occasionally met with in the lungs. Such productions he correctly regarded as the result of perverted secretion, and he had

never met with them, except in dilated branches of the bronchiæ, or in the vicinity of old tuberculous excavations, cured by the formation of a fistula, or cartilaginous cicatrix. The production of cretaceous matter, he says, frequently succeeds that of tubercles.

Dr. Forbes coincides with Laennec respecting the secretion of the chalky matter; but differs from him in believing, with the author of this work, that the habitual inhalation of dust of various kinds is a frequent source of bronchial inflammation among various kinds of artisans, and more especially, in this country, needle-grinders, leather-dressers, and miners. An immense proportion of the miners in Cornwall, he says, are destroyed by chronic bronchitis, one cause of which is the inhalation of dust.]

Exposure to the VAPOUR OF MINERAL ACIDS, or of metallic or other mischievous exhalations, is also frequently found to produce a permanent difficulty of breathing. This affection is peculiarly common to those wretched beings who are condemned by the laws of their country to work in metallic mines as an expiation of crimes proved against them; a melancholy and interesting picture of whom is given by Diodorus Siculus, in his description of the mines of Arabia and Ethiopia. The air-cells of the lungs are often found constricted to half their proper capacity; whilst, in many mines, the vapours are so irritable as to excite a perpetual cough. They are loaded, according to the nature of the mine, with oxides, sulphurets, or comminuted reguline particles of lead, copper, antimony, silver, arsenic. Metallurgists and the labourers in chymical laboratories are often severe sufferers from a like cause. Gold-refiners become dyspnoetic from inhaling the vapour of aquafortis. Etmuller gives an account of his having been seriously injured in his breathing while carefully superintending an antimonial preparation.—(*Ranmazini, de Morbus Artificum*.—*Ephem. Vratisl.*) And Heurnius saw the lungs of a printer, so changed by inhaling an atmosphere impregnated with lead, as to resemble a shrivelled apple.

The treatment of this variety must be regulated by the variety of the cause; but, perhaps, in all cases, a free inhalation of oxygen gas will be serviceable. An inhalation of moderately stimulant vapours, as of an infusion of lavender, marjoram, and, indeed, most of the verticillate plants, or of diluted wine-vinegar, has also proved frequently of use; to which may be added, a current of the electric fluid passed two or three times a day from the upper part of the spine to the diaphragm. An atmosphere impregnated with tar heated over an oil or spirit lamp, has also in many instances been found essentially to invigorate the respiratory powers; and to these, where there is much cough, should be added expectorants and the warmer demulcents. After pursuing this plan for some weeks, pure air and the aerated mineral waters, where the case is not inveterate, will add a healthy degree of tone, and restore the respiratory organs to their natural action. Galvanism has also occasionally produced considerable, and,

in some instances, permanent relief, after a few applications; the opposite wires being applied, the one to the nape of the neck, and the other to the lower part of the epigastric region, and each fixed upon a thin plate of metal wetted with water, as recommended by Dr. Wilson Philip.—(Op. cit., p. 379.)

We sometimes find a permanent difficulty of breathing in persons labouring under GREAT TORDOR OR SLUGGISHNESS OF VASCULAR ACTION. The pulse is slow and unresisting; the muscles are soon fatigued; the mind has little energy; the face is pallid; the skin cold and soft: the urine scanty, and the extremities œdematous, without any pathognomonic symptoms of dropsy in the chest, or at least any sensible fluctuation in the thorax. It is the *dyspnœa aquosa* of Cullen, and the *dyspnœa pituitosa* of Sauvages. Whatever has a tendency to depress the living power, and particularly in flaccid and atonic habits, will readily lay a foundation for this variety of dyspnœa; and hence it is a frequent result of catching cold in the feet, and, still more frequently, of suppressed perspiration. It also occasionally follows chronic catarrhs, and pneumonitis.

A tonic and gently stimulant plan, consisting of the warm gums, camphire, and other terebinthines, the warmer bitters, the oxydes of zinc and iron, the compound squill pills, the warm-bath, moderate exercise, and a generous diet, will be the most successful mode of treatment; occasionally interposing antimonial emetics; which will relieve the lungs far more effectually than those of *ipeacacuanha*, as operating longer on the moving powers of the chest. Of the terebinthinate tribe, the best, perhaps, is the balsam of copayva, given in doses of a drachm or a drachm and a half three or four times a day. Nothing succeeds so well in restoring the secretion of mucus where it has ceased or become deficient; or in producing a healthy discharge where its nature has been changed by morbid action: on which account, this medicine may almost be regarded as a specific in morbid secretions of mucous membranes, whether of the lungs, the intestinal canal, or the urethra; as it has often proved highly serviceable in croup. The chief difficulty is in devising a convenient form for its exhibition, since it sometimes excites nausea.

The variety of least moment, perhaps, to the dyspnoetic patient, is that which proceeds from, or is accompanied with, a short, stunted figure, and considerable corpulence, or, at least, OBESITY OF THE CHEST. We see persons of this description, significantly described by the colloquial term *pursy*, pant, and perspire, and grow fatigued, day after day, upon very little exercise, and yet press on without any serious inconvenience to a late period of life; or, if they sink suddenly and sooner, they yield rather to apoplexy as a result of their general habit, than to the idiopathic affection before us. [According to Laennec, this case is in a great measure nervous, and is to be attributed to the great expenditure of nervous influence, required to move a mass so disproportioned to the ordinary

powers of motion.—(Op. cit., p. 404.)] Abstinence from spirits, wines, and fermented beverages, a meager allowance of animal food, a soluble state of the bowels, and exercise, rather persevering than violent, will form the best plan for the present ease, and the best guard against threatened mischief. Bleeding has often been tried, but it affords only temporary relief. Sauvages gives us the history of a female, who for two years had been so far suffocated, that it had often been judged necessary to bleed her three times a day at least, and she had undergone not fewer than two thousand venesections, when she applied to him. She was plunged into a warm bath, the bath was frequently repeated, and friction at the same time made use of, so as to excite violent perspiration: by this means she was convalescent in ten days.

Dyspnœa has also sometimes been produced by causes somewhat more singular, as common respirable air obtaining an entry into cavities in the chest, or to which it does not naturally belong. Stoll gives a case of dyspnœa, in which air-bladders, or vesicles, were seated on the surface of the lungs.—(Rat. Med., part vii., p. 135.) [This state is particularly described by Laennec (Op. cit., p. 149) in his valuable account of emphysema of the lungs: after mentioning the enlargement of the air-cells, he says, sometimes we observe on the surface of the lungs single vesicles, distended to the size of a cherry-stone, or even larger, quite prominent, exactly globular, and apparently pediculated. The term *apparently* is used, because, on cutting into them, we find that there is no real pedicle, but merely a constriction at the point where the cell begins to rise beyond the surface of the lungs. The dilated cell, in fact, communicates with the adjoining ones and the bronchiæ; and the case is not one of a mere extravasation of air under the pleura. What he calls pulmonary emphysema consists essentially in the dilatation of the air-cells; and the projection of air on the surface of the lungs, constituting the larger and more prominent vesicles, is a posterior affection, and of slight importance, compared with the dilatation of the cells; because hopes may be entertained of its removal by absorption, while we cannot well see how nature or art can remedy the other morbid alteration, which, however, Laennec does not pronounce absolutely incurable.] Gooch and various others mention examples of air let loose between the lungs and the pleura. In Timæus we have a specimen of a very extraordinary idiosyncrasy, giving rise to a difficulty of breathing upon an inhalation of the smell of roses.—(Case, p. 216.) The morbid influence of metallic action is not confined to vapour locally applied; for in Schenck we have a case of dyspnœa produced by mercurial inunction (Observat. Rad., lib. ii., p. 63); and, in other books, of a like effect on peculiar constitutions by a solution of the oxydes of lead taken internally, or even applied externally.—(Eph. Nat. Cur., dec. iii., ann. iv., obs. 30.)

[According to Laennec (Op. cit., p. 151), some of the air-cells of the lungs of subjects

who have long suffered from any kind of dyspnœa, are almost always found preternaturally dilated. In other words, these organs are in a state of *vesicular* or *pulmonary* emphysema, which he distinguishes from the *interlobular*, well known to surgeons. He looks upon vesicular emphysema as being almost always the consequence of dry catarrh, and presenting the same indications of cure. "Frictions with oil are often very useful in lessening the susceptibility to be affected by catarrh. In the case of pallid, cachectic subjects, the subcarbonate of iron has occasionally seemed to have a similar effect, and to tend at the same time to diminish the congestion of the mucous membrane, and spasmodic stricture of the bronchiæ. In the severer asthmatic paroxysms, it is frequently necessary to have recourse to venesection, in order to relieve the congestion of blood in the lungs; and it is always proper to diminish the necessity of respiration by means of narcotics."*†

Chronic dyspnœa appears also as a symptom or sequel in various other diseases, or affections of various other organs; as aneurism, ossification, or other mischief in the heart, or aorta; any morbid change in the diaphragm, ribs, or pleura, by which the cavity of the thorax is diminished, or the moving powers restrained in their action; parasympic enlargements of the liver, spleen, or omentum; whence it is obvious, that it must, in a greater or less degree, be an attendant on the latter period of pregnancy. It has also followed occasionally, not only suppressed perspiration, but the suppression of various cutaneous eruptions, and in a few instances, the sudden closure of an issue, or seton, of long standing.†

SPECIES II.

DYSPNŒA EXACERBANS.

EXACERBATING ANHELATION.

THE DISEASE SUBJECT TO SUDDEN AND IRREGULAR EXACERBATIONS; BREATHING DEEP, STERTOROUS, ACUTE, AND SUFFOCATIVE; RELIEVED BY AN ERECT POSITION.

This species admits of most of the varieties of the preceding, which it is hence unnecessary to repeat; and, like it, is often found as a symptom in aneurisms, polypous concretions, and other affections of the heart and larger vessels; in parasympia, and other affections of the abdominal viscera; in empyema, dropsy of the chest, worms, peripneumony, bastard peripneu-

mony, smallpox, and occasionally in severe accessions of intermitting fevers. I have already, indeed, stated, that there is scarcely a function with which the action of the lungs is not connected, and, consequently, scarcely a disease of any importance in which it does not occasionally participate. Whatever be the cause that produces anhelation, or permanent difficulty of breathing, in a patient, any accidental augmentation of it, or any sudden excitement of body or mind, or any diseased action of any kind, capable of uniting with the primary cause, directly or remotely, will increase its power, and not unfrequently induce a spasmodic constriction in the muscles of respiration. And it is this accidental exacerbation, produced irregularly by casual and often occult causes, and especially in irritable or nervous temperaments, that peculiarly distinguishes this species from the preceding. In asthma the returns are for the most part strictly periodical, and the intervals perfectly free from difficulty of breathing. In exacerbating dyspnœa the constriction occurs with the utmost irregularity, in the daytime, at night, in hot or cold weather, in a moist or dry atmosphere, and it is hence sufficiently distinguished from asthma. A catarrhal cough will sometimes prove an occasional cause; several of the varieties of heart-burn, and especially *cardialgia syncopalis*, still more frequently; other causes are, indigestible food, a fit of hysterics, or any violent commotion or agitation: while, as already observed, the occasional cause is often beyond the power of detection.

When the constrictive paroxysm makes its attack, it must be immediately opposed by an erect position, without which suffocation would often instantly ensue; and by the most powerful antispasmodics. Tincture of opium, ether, and ammonia, are what I have chiefly trusted to, and have uniformly found far more to be depended upon than castor, or any other odorous antispasmodics, in whatever quantity given. A large blister to the chest should also be immediately applied; and, if the paroxysm do not yield soon, sinapisms to the feet. Upon its cessation, the gum-ammoniac mixture, or a solution of asafetida, with camphorated tincture of opium, will be found a convenient guard against fresh attacks, provided due attention be paid to the state of the bowels, which ought indeed to form an early consideration. Issues have been recommended as a preventive of the paroxysm, where its approach has been expected, and I

* Moderate venesection will be found useful in several of the forms of dyspnœa noticed by the author, particularly in that arising from great torpor or sluggishness of the vascular action.—D.

† Riedlin, *Lin. Med.*, 1695, p. 91. There is a form of dyspnœa, noticed by Laennec, and described by him as a "*besoin de respirer*," and by Dr. Williams, as a case of "*increased want of breath*;" a disorder which the latter physician refers to the venous condition of the blood being augmented beyond its natural standard. If not idiopathic, this affection, he thinks, cannot be ascribed to any distinct disease. It is to be detected only by the absence of the signs of every other

cause: when, therefore, a dyspnœa occurs, while pure air is found to penetrate freely into every part of the lungs, and the diseases, which modify the state of the bronchial membrane and its secretion, have not existed, the disorder, as Dr. Williams conceives, must be necessarily referred to an unusually venous or carbonized state of the blood; the result, perhaps, of "an excessive formation of those secretions, which are, in relation to the blood, defective in carbon" (*Cyclop. of Pract. Med.*, art. *DYSPNŒA*), as, for instance, urea. Belladonna, stramonium, and conium, are the medicines which Laennec preferred for the relief of the "*besoin de respirer*."—ED.

have sometimes thought them of efficacy. For this species, however, perhaps the most effectual means of relief are to be derived from the application of the voltaic battery, as already proposed for anhelation from poisonous vapours; and as has been successfully tried in numerous instances of the present species by Dr. Philip, who was first induced to apply this remedy from observing that animals, whose eighth pair of nerves had been divided, exhibited the oppressed breathing and accumulation of phlegm that characterize both species of dyspnœa, and were relieved by having a stream of voltaic aura sent through the lungs.

The accompanying cough, instead of being increased by the use of the voltaic power, is hereby diminished, in consequence of its diminishing the accumulation of phlegm in the lungs. In proper asthma, which is characterized by intervals of free and healthy breathing, little or no benefit has been derived from this process; and hence Dr. Philip very ingeniously reasons, that although in both diseases the nerves of the respirable organ are alone in a morbid condition, and not the brain or spinal marrow; yet, in the former, they are still capable of being recalled to a state of healthy activity, or of becoming sufficiently cleared to form a passage for the supply of nervous influence to the lungs, which effect he supposes to be obtained by the use of the voltaic machine.

The American pathologists have found great benefit from various preparations of the *lobelia inflata*, or Indian tobacco, which certainly possesses powerful antispasmodic and expectorant virtues; and has hence a fair claim to more extensive trial than it has yet received. The ordinary form is that of a saturated tincture of the leaves, prepared by digesting two ounces in a pint of proof spirit: the dose of which is from a tea-spoon to a table-spoonful, repeated every half hour, or oftener, till the paroxysm is conquered.*

GENUS IV.

A S T H M A

ASTHMA.

DIFFICULTY OF BREATHING TEMPORARY, RECURRENT; ACCOMPANIED WITH A WHEEZING SOUND AND SENSE OF CONSTRICTION IN THE CHEST; WITH COUGH AND EXPECTORATION.†

ASTHMA, as already observed under dyspnœa, is closely connected with the latter, and particularly with its second species, characterized by what might be strictly called asthmatic exacer-

bations, and which I have hence denominated *dyspnœa exacerhans*.

The definition of the disease now offered, while it shows the proximity of the one to the other, is sufficient, if I mistake not, to form a marked and accurate distinction. The vulgar term for the complaint in our own language is *broken-wind*; which, as scientific precision is seldom an object of popular language, is often also applied to some of the varieties noticed under dyspnœa, or *short-breath*.

Asthma is more commonly a disease of the later, than the earlier period of life; for it does not often appear in infancy or youth, although occasional instances of this have occurred, particularly in infancy, that have been mistaken for cases of croup, which the asthma of infancy very much resembles, though admitting of a more easy cure.* It soon becomes habitual, and seems sometimes to be hereditary.

Asthma afflicts both sexes, but is more common in the male than the female. It makes its appearance in individuals of every variety of constitution, a necessary result, as Dr. Forbes remarks, of its frequent dependance on other diseases of accidental occurrence; but what are called nervous temperaments are those in which the disorder occurs with remarkable frequency, and the same observation may be made with respect to plethoric individuals, with a full hard pulse, a short neck, high shoulders, a great deal of fat, and a voluminous head. It is supposed to be more common in temperate climates, than in either the very cold or the very warm regions of the earth.† Frank found it more common in Poland than Italy.—(Frank, *Med. Univ. Prax.*, tom. vii.)

The paroxysms of asthma are frequently preceded by languor, flatulence, headache, heaviness over the eyes, sickness, pale urine, disturbed rest, and a sense of straitness, fulness, and anxiety about the præcordia. "When the evening approaches," says Dr Bree (*Inquiry into Dis. Respiration*, sect. iv., p. 46), who unhappily describes from his own history, "the weight over the eyes becomes more oppressive, and the patient is very sleepy. Frequently, at this period, there is a tingling and heat in the ears, neck, and breast; and a motion to expel the contents of the bowels is attempted, with

attended by circumstances, which are noticed more or less in all cases, where there is some obstacle to the mechanism of respiration."—Jolly, *Dict. de Méd. et de Chirurgie Pratiques*, art. *ASTHME*, 1829.—ED.

* Asthma, according to the definition commonly given of it, is sometimes considered to be less a disease of old persons, than of adults not so far advanced in years; for the dyspnœa, and disturbance of the respiratory functions, often noticed in aged individuals, are mostly dependant upon organic diseases of the heart, or great bloodvessels, as M. Rostan has satisfactorily proved.—En.

† "A difficulty of breathing, recurring in paroxysms, after intervals of comparative good health, and usually unaccompanied by fever."—(Forbes in *Cycl. of Pract. Med.*, art. *ASTHMA*.) The greater number of writers agree in meaning by *asthma* "a disorder of the respiratory organs, characterized by intermittent or remittent dyspnœa, the attacks of which usually occur during the night,

† The prevalence of asthma seems to depend more upon the humidity of the atmosphere than upon its high or low degree of temperature. It is more likely to affect individuals on the seaboard than in the interior, and is seen in Boston and New-York more frequently than in Philadelphia.—D.

* A Treatise on the Materia Medica, &c., by John Eberle, M.D., 2 vols., 8vo., Philadelphia, 1822. Also Dr. Andrew's Report in *Glasgow Med. Journ.*, vol. i., p. 177.

some violence, and with great uneasiness of the abdominal muscles. When an asthmatic feels these warnings, he may be convinced that his enemy is at hand."

The accession is usually about the middle of the night, and during the first and deepest sleep: the cause of which has not been rendered very manifest, though I do not think it beyond the reach of explanation, and especially in constitutions predisposed to the disease by habit, or hereditary affection. Respiration always takes place most easily in a raised or erect position, but in the night the body is recumbent. Respiration is also so much of a voluntary action, that although it continues during sleep, and when the will is not exerted, it is considerably aided by the concurrence of the will. Now, during sleep, this concurrence is wanting; and hence the most favourable period for the attack of this insidious complaint is that, in which we actually find it makes its appearance—during a recumbent position of the body, when the muscles of respiration are destitute of the stimulus of volition. When the disease indeed has once established itself and become habitual, it will recur at other times also, but less frequently.

For the most part, the patient wakes suddenly, and feels a most distressing tightness about the chest, as if he were bound with cords: his anxiety is inexpressible, and he labours for breath as though every moment would be his last. He is obliged to sit erect, breathes distressfully with a wheezing sound, and cannot bear the weight of the bedclothes. Cool fresh air is the object of his intense desire.* At the same time, the extremities are cold; the heart palpitates; the pulse is sometimes quickened, but usually weak, irregular, and often intermitting; the abdomen is distended with flatulence; the stomach is faint, and often rejects with great violence a slimy and frothy material of a greenish or yellowish hue. The eyes stare prominently, and the face is sometimes pale, but more commonly bloated and livid; and the alvine canal, though costive before, will now perhaps pass a loose stool.

In many instances, there is an ineffectual effort to excrete, with a harsh and dry cough that brings up nothing more than a little clammy or frothy mucus. And in these cases, the fit usually subsides, or perhaps altogether leaves the patient in two or three hours. But, in other instances, the cough is far more violent and suffocative; and when it has lasted for an hour or two, an expiration of tough viscid mucus commences, and gradually becomes copious and affords relief. It is occasionally mixed with blood from the severity of the struggle; but the

larger the discharge of either, or of both, the more the bronchial vessels are relieved.

It is often, however, many hours before a paroxysm of this kind very sensibly subsides; and the patient generally feels some degree of constriction during the whole of the ensuing day; and is fortunate, if the next night be passed without a similar fit. The tendency to such returns usually continues for several nights; in severe cases, for a week or fortnight. Sir John Floyer, who, from describing his own sufferings, has given us one of the best historical accounts of the disease that has ever been written, mentions a case, in which the fits recurred for seven weeks together; during the whole of which time the patient was obliged to sit erect in a chair.

Yet, notwithstanding the violence of the assault, it is not often that asthma, under either of these forms, proves fatal at the time: for this "*morbis maximè terribilis*," as it is called by Willis, "may be carried on to old age, if supervening diseases do not destroy the patient, or disturb the operations of nature, by which a recovery from the paroxysm may be obtained."* But it rarely makes a first attack without subjecting the constitution to subsequent returns; and frequently, by the debility which it hereby produces, lays a foundation for tubercular phthisis, dropsies of the chest or abdomen, aneurisms of the heart, and various other fatal diseases [which, however, according to the editor's reasoning, should generally be considered as causes, and not as effects of the disturbance of respiration]. While it occasionally happens, even where none of these take place, that the mucous glands of the bronchiæ become relaxed, an habitual excess of secretion ensues, and a troublesome dyspnoea is the consequence, from the overloaded state of the air-cells and bronchial vessels; a mischief, which, in such cases, is felt most oppressively on first awaking, and is only relieved by a long labour of severe coughing. This overloaded state of the bronchiæ and air-cells, from too large a secretion of mucus, is indeed, at the time, an original exciting cause of the disease; and has by some writers, and especially in our own day by Dr. Bree, been supposed to be the chief cause.

The exciting causes, however, are numerous, and it is difficult to say which is the chief; nor always easy to ascertain them satisfactorily. Yet they may all be resolved into an irritation of some kind or other, existing within the cavity

* Dr. Forbes has known a poor patient, in such circumstances, not merely remain by the open window, but lean over it, resting on the sill, with the arm hanging on the outside, for several nights together, and even in winter.—(Cyclop. of Pract. Med., art. ASTHMA.) Exposure to cold during a paroxysm of asthma rarely causes any immediate or subsequent ill consequences, a fact which appears to Dr. Forbes to prove how profoundly and extensively the nervous system is involved in the attack.—ED.

* Bree's Inquiry, &c., sect. vi., p. 71. Asthma hardly ever proves fatal as asthma, that is, in the paroxysm; but, as Dr. Forbes has very correctly explained (Cyclop. of Pract. Med., art. ASTHMA), its frequent recurrence not merely aggravates the pathological states in which it has originated, but leads directly to the production of other diseases. "The most common of these," he says, "are emphysema of the lungs, dilatation of the heart, hydrothorax, and other forms of dropsy. But," adds this well-informed physician, "if asthma is rarely fatal, it may be said to be almost as rarely cured, if this epithet is applied only to the entire and permanent removal of the disease. It is, however, frequently susceptible of great mitigation and retardation of the paroxysms."—ED.

of the chest, and stimulating its moving powers to a convulsive constriction.* I say existing *within* the cavity of the chest, because we are now considering asthma as an idiopathic disease. Yet it happens not unfrequently, that it occurs as a mere symptom, or result of some other disease, or of a morbid state of some remote organ, as the stomach, liver, or spleen; in which case, it becomes a secondary affection, and is only to be removed by removing the primary disorder on which it is dependant.†

[The ancients confounded, under the name of *asthma*, several varieties of dyspnœa, arising from different organic diseases, and which they very incorrectly regarded as nervous affections. To *Corvisart* and *Rostan*† belong the merit of having thrown a great deal of light on those varieties, in particular, which depend upon organic diseases of the heart and large blood-vessels.]

Whether the suffocative tightness of the chest be the result of a spasmodic stricture of the bronchial vessels, spreading thence to the muscles of respiration, or produced by an infarction of these vessels from a superabundant effusion from their exhalants, is a question of a very different kind. *Willis* first started the former opinion, which has flowed in a regular current, or with little opposition, through *Floyer*, *Hoffmann*, and *Cullen*, to the present day. [Its possibility has lately received important corroboration from the anatomical researches of *Reisseissen* (*F. D. Reisseissen Ueber den Bau der Lungen.*, Berl., 1822), who has ascertained the existence of a set of completely circular fibres around the bronchial ramifications, beginning at the point where the cartilaginous circles terminate. *Laennec* (Op. cit., p. 408) has also verified the correctness of this observation upon branches of less than a line in diameter; and he remarks that, although it be difficult to follow the muscular fibres to a greater distance, analogy leads us to admit their existence, certainly in the smaller branches, and, perhaps, even in the air-cells. Adopting this view of the subject, he conceives that the spasmodic contraction of these fibres may take place in such a degree as to prevent the transmission of air to a great portion of the lungs. It is also further maintained by *Laennec*, that the study of respiration, by means of auscultation, furnishes

us, both in health and disease, with proofs of the lungs possessing an inherent power of action. This author is too intelligent, however, to refer asthma exclusively to the operation of any single uncombined cause.] *Dr. Bree* has lately proposed the second doctrine above specified, and supported it with great ingenuity and learning; illustrating and fortifying his views by numerous references to unquestionable facts, and the opinions of earlier writers. The same principle, or at least a modification of it, has been adopted by *Dr. Parry*, who places the vascular turgescence in the mucous membrane lining the bronchial cells.

Admitting the former hypothesis, the thoracic convulsion is a diseased action from the beginning, and under every degree and modification, and is so regarded by its advocates: while *Dr. Bree* only allows it to be so when the convulsive action is violent; contending that in its commencement it is altogether a remedial effort, an instinctive attempt to expel the serum or mucus that clogs the bronchial vessels. And he hence accounts for the pathognomonic wheezing, which he does not think the idea of a spasmodic stricture of these vessels is sufficient to explain; as also for the general inefficacy of opium and antispasmodics, to whatever extent they may be carried.

I have already stated, that an excessive secretion from the exhalants of the bronchiæ may be an exciting cause in many cases, and particularly in a relaxed and debilitated condition of the bronchial vessels in consequence of former attacks. But, notwithstanding the masterly manner in which *Dr. Bree* has argued this point, I cannot regard such a secretion as a common cause of asthma, since, in numerous instances, I have observed in the words of *Sir John Floyer*, that “the lungs do not appear to be much oppressed with phlegm before the fit; and, at the end of the fit, the straitness goes off *before* any considerable quantity is spit up:” while in what is commonly called the dry, nervous, or convulsive asthma, there is always very little, and sometimes no mucus whatever, excreted from the beginning to the end of the paroxysm. It may, indeed, be maintained, that the secretion is absorbed, but this is to beg the question, for we have no proofs of such an absorption. The existence of accumulated mucus in the bronchial vessels of those who have died of asthma, and whose bodies have been opened, does nothing more than establish the fact in those particular cases. And even here we are left in total darkness, whether the serum or mucus anticipated the suffocative convulsion, and was the cause of it, or whether the latter anticipated the serous or mucous effusion, and forced it into the vessels in which it has been found on dissection. How far the suffocative convulsion may originate in a spasm of the bronchiæ, as contended for by *Dr. Cullen*, we have no means of determining manifestly. That it may exist, however, as well as a spasm of the alimentary canal, no one has been bold enough to deny; that it must produce that strangling constriction or straitness which is a pathognomonic sign of asthma, where it does

* On this part of the subject, what *Willis* has stated is put, as *Dr. Forbes* has rightly observed, in pithy terms:—“Asthmatics can bear nothing violent or unusual. From excess of heat or cold, from any great bodily exertion, or mental emotion, from change of season or weather, from errors, even of a slight kind, in the non-naturals, and from a thousand things besides, they fall into fits of dyspnœa.”—*De Med. Op.*, p. 209.—*Ed.*

† Among the predisposing causes may be enumerated hereditary transmission; malformation of the chest; small size of the glottis; excessive irritability of the bronchial membrane; and all diseases which directly affect it, as catarrhs, bronchitis, &c. But of all the predisposing causes of asthma, dyspepsy is the most frequent.—*Ed.*

‡ *L. Rostan*, *Mém. sur cette question: l'asthme des vieillards est-il une affection nerveuse?*—Paris, 1809.

exist, can be as little doubted; and I find it extremely difficult to ascribe the disease to any other state of the bronchiæ, in all cases of dry or nervous asthma, in which, as there is little or no discharge from the lungs, we have full ground for inferring, that there is little or no accumulation within them. "It is not, however, intended," says Dr. Bree, "to deny the possible existence of this spasm, but to object to it as a proximate cause; and to state the imprudence of depending upon it as an important indication in practice."—(*Inquiry, &c.*, sect. vii., p. 106.) Yet it does not appear to me, that the practice suggested by the one opinion needs to be so much at variance with that suggested by the other, as this passage would seem to intimate. For, if acids prove a beneficial mode of treatment, and that benefit be ascribed by the upholder of the muculent hypothesis to the astrigent power of the acid, by which the flow of mucus is restrained; it may be ascribed by the upholder of the spasmodic hypothesis to the very same power, by which, as a tonic, it takes off irritability, and allays all muscular irregularities.

[Laennec (*Op. cit.*, p. 405–407) has divided the form of asthma, in which no organic lesion is discoverable, into two kinds; in one, when the chest is examined with the stethoscope, the respiration is very sonorous, like that of children; and hence he calls the disease *asthma with puerile respiration*.* In this instance, the patient constantly feels the want of a more extensive respiration than what he enjoys. The dyspnoea is frequently very intense, and is sometimes so aggravated by the slightest motion, that the patient is condemned to a life of inactivity. Laennec ascribes the disease to the state of the nervous system. He has never met with this species of asthma, except in persons affected with chronic mucous catarrh. The other form of asthma noticed by Laennec as unconnected with organic disease, is what he names, with other writers, *spasmodic asthma*.]

Dr. Bree's division of the disease is founded upon causes, rather than upon symptoms; and he has hence divided it into the four following species:—Firstly, those cases, being most numerous and common, which are produced by the irritation of effused serum in the lungs. Sec-

ondly, those produced by the irritation of aerial acrimony in the lungs. Thirdly, those dependant on irritation in the stomach, or some of the abdominal viscera, and fourthly, those dependant upon habit.

[The author of the present work has not adverted to the valuable writings of Laennec on this subject, who shows that the most common cause of dyspnoea, when of sufficient severity to be termed asthma, is a dry catarrh inducing emphysema of the lungs, that is to say, a preternatural dilatation of the air-cells. In some rare cases, where the progress of œdema of the lungs is very slow, asthmatic symptoms may also be produced. These morbid states have been amply verified by morbid anatomy.]

As the definitions, under the present classification, are founded upon a principle of symptomatology rather than of etiology, it will not be in my power to adopt Dr. Bree's divisions in the exact terms and order in which he has given them; though it will be found that his first two species run nearly parallel with the only two to which I propose to limit the genus; and which will be wide enough to embrace his fourth, or those cases of the disease which, whatever be their symptoms, depend on an established habit: while the third species of Dr. Bree, comprising cases in which asthma is not an idiopathic affection, but a sign or result of morbid action in some organ remote from the lungs, cannot be correctly treated of in the present place; the affections included under it being alone to be remedied by remedying the primary disease on which it is dependant.

From the view then thus offered, and from other symptoms that we shall have presently to take notice of, it will, I think, be found convenient to contemplate the genus *ASTHMA*, as comprising, and limited to, the two following species:

1. Asthma Siccum. Dry Asthma. Nervous Asthma.
2. ——— Humidum. Humid Asthma. Common Asthma.

SPECIES I.

ASTHMA SICCUUM.

DRY ASTHMA. NERVOUS ASTHMA.

PAROXYSM SUDDEN, VIOLENT, AND OF SHORT DURATION; CONSTRICTION HARD, DRY, SPASMODIC; COUGH SLIGHT; EXPECTORATION SCANTY, AND ONLY APPEARING TOWARDS THE CLOSE OF THE FIT.

* Dr. Forbes has given the following explanation of what is revealed by the stethoscope, which "conveys scarcely any respiratory sound during inspiration, except an indistinct hollow sort of murmur, altogether unlike the usual respiratory sound, and so slight as to leave it doubtful if the impression conveyed to the ear is really a sound or vibration. Expiration, however, is distinctly marked over the greater part of the chest; not, indeed, by the sound of healthy respiration, but by a loud, sibilant, or dry sonorous rhonchus, corresponding with the loud sighing wheeze, audible by the naked ear. This rhonchus is often exactly like the sighing of wind through crevices; and sometimes the tone and key of the sound approach nearer those of a moan than a sigh. The sounds are perceptible during expiration over the whole chest, even in the extreme points of the lungs; and equally so in patients, whose respiration is nearly inaudible in the intervals of the paroxysms."—*Cyclop. of Pract. Med.*, art. *ASTHMA*.—Ed.

This is the proper convulsive or nervous asthma of Willis, Hoffmann, Floyer, and Aken-side. Its predisposing cause we are sometimes capable of developing; for we can trace the disease to a morbid structure of the chest, to an irritable condition of the bronchial vessels, or parenchyma of the lungs, produced by a pleuritis, or a succession of severe and protracted winter coughs, or to an hereditary source. Of the occasional causes, however, we are often in great ignorance; and mostly so where the disease appears in its simplest character, and to-

tally unconnected with any other affection. In some instances, it evidently follows the sudden repulsion of cutaneous eruptions; in others, the sudden cessation of œdematous swellings in the extremities of cachectic patients; and, not unfrequently, the inhalation of deleterious exhalations: most of which we have already noticed as occasional causes of dyspnœa, and dry or humid cough. So that it is probably a mere difference in the constitution or habit that renders these causes capable of producing one of these diseases rather than another. And hence dry asthma, like the preceding, as thus diversified by its occasional causes, may be contemplated under the following varieties:—

- | | |
|--------------------------|--|
| a Simplex. | Without any obvious |
| Simple nervous asthma. | cause or connexion with any other affection. |
| β Metastaticum: | From retropulsion of |
| Repelled eruptions. | some cutaneous affection. |
| γ Phlegmaticum. | From repelled œdema |
| A cachectic frame. | of the extremities in phlegmatic or cachectic habits, with a scanty secretion of urine. |
| δ Vaporosum. | From inhaled fumes |
| Deleterious exhalations. | of metals, especially of lead and arsenic; of sulphur, charcoal, nitric acid, and other deleterious or poisonous substances. |
| ε Organicum. | From organic derangement of |
| Organic misformation. | the walls or contents of the chest. |

THE FIRST OF THESE varieties constitutes the second species of Dr. Bree, who supposes the unknown and exciting cause to reside in some "subtile acrimony *always* present in the atmosphere in a greater or less degree, and ready to be inspired."—(*Inquiry*, &c., p. 192.) It is at least difficult to disprove this opinion; but, admitting the fact, we can make little use of it, and are nearly as much in the dark as ever.

It is a position of far more general assent, that this modification of asthma is more likely to occur "in proportion as the habit is disposed to the condition called nervous."—(*Op. cit.*, p. 191.) The paroxysm, indeed, frequently makes its attack under those circumstances, which are most apt to try the strings of a nervous temperament. A sudden emotion of the mind will give rise to it; an alteration of the wind, a change of residence, or a meal that disagrees with the stomach; and often there is a considerable evacuation of pale urine: while on the contrary, as already observed, it more usually makes its attack without any one of these harbingers, or any other that can be traced out. The small quantity of viscid mucus that is excreted through the whole of the struggle, proves evidently, that the inner membrane of the bron-

chial vessels is in a state of peculiar dryness; and leads us to conceive, that, at the onset, it was nearly or altogether destitute of its lubricating fluid. It is on this account that the cough and wheezing are both slight.
